New Charts.—34—England, South coast :—The Scilly isles. 3601—Scotland, west coast :—Loch Dunvegan, including Loch bay. 2582—Orkney islands :—Pierowall road and approaches. 3578—Spain, south coast :—Eastern approaches to the strait of Gibraltar. 337—Canada, Lake Ontario :—Toronto harbour. 1313—Chile; the channels between Maullin bay and port Montt. Plans :—River Maullin, port Abtao, port Montt. 3594—British Columbia; plans on the east coast of Vancouver island :—Ganges harbour and Captain passage; Porlier pass. 69—Ceylon :—Pámbam pass. 3615—Plans in the Philippine islands :—Santa Cruz harbour; port Banalakan; port Boca Engano. 905—Philippine islands :—Ports Masinlok and Matalvi and Palauig bay. 3588—China :—Canton river delta. China, north coast :—Kyau chau bay to Lai chau bay. 913—Korea, west coast :—Mackau group to Clifford islands. Plan :—Ochon to anchorage (Palos harbour). 3114—Japan :—Izumi and Simonoseki ko. 8566—Japan : — Izumi Nada and Harima Nada. Plans :—Yura ko; Sumoto ko; Kata Seto.

New Plans and Plans added.—633—Harbours and anchorages on the east coast of Ireland. New plan :—Malahide inlet. 2063—Malta island, northern portion. Plan added :—Ras in Nieshfa bay. 708—Anchorages on the west coast of Madagascar. New plans :—Nosi Mitsio (Minow islands); Ampasimena (Diamond) bay. 944—Ports in the Philippine islands. New plan :—Port Batan. 991—Anchorages on the coast of Yezo island. New plan :—Kushioro road. 3409—Japan :—Ishinomaki wan (Sendai bay) and Sakata ko to Tsugaru Kaikyo. Plan added :—Obato wan. 210—Japan :—Harbours on the east coast of Nipon. New plan :—Yamada ko. 1648—Japan :—Osumi Kaikyo (Van Diemen strait) to Oshima. Plan added :—Osumi group. 3340—Gulf of Tartary, northern sheet. Plan added :—Sertuna river anchorage. 845—Fiji :—Kandavu passage to Kowata island. Plan added :—Likuri island anchorage. 1386—Islands in the south Pacific ocean. New plan :—Cook bay or Hanga road.

Charts that have received additions or corrections too large to be conveniently inserted by hand, and in most cases other than those referred to in the Admiralty Notices to Mariners : — 1967 — England, south coast : — Plymouth sound. 2978 — Iceland : — Sigle fiord to Niardvig. 2172—Alaska: —Bering strait. 2908—Africa, south coast :—Port Natal entrance. 2062—Cochin China :—Ton king gulf. 3349 — China :— Approach to Kwang chau wan. 1055—Korea :—Southern approach to Ping Yang inlet.

These charts are issued by Mr. J. D. Potter, 145, Minories.

RUSSIAN STEAMSHIP SUBSIDIES.

Russia seems determined to do all in her power to revive her Oriental trade, and to advance her commercial interests in the Eastern world. To this end, she has been systematically at work granting subsidies to lines of steamships plying between her own ports and those of China, Japan, and other ports of Asia. Contracts have been made this year by the Russian Government for subsidised steamship services from Vladivostok to ports of China and Japan, and also along the coast to Nikolaievsk, Petropavlovsk, and other ports. The contract for the China and Japan lines, is for one year, and was given to the Russian East Asiatic Steamship Company, which is closely connected with the Danish East Asiatic Company. It provides, first for a weekly mail and passenger steamer from Vladivostok to the Japanese port of Tsuruga, which lies to south-east on the Japan Sea. This trip, according to the American Commercial Agent at Vladivostok, is scheduled to be made in thirty-eight hours, and from Tsuraga, Kobe and Osaka can be reached by train in eight hours, and Tokyo in fourteen hours. Secondly, for a weekly mail and passenger steamer from Vladivostok to Shanghai, *viâ* Nagasaki, and back by the same route. The voyage from Vladivostok to Nagasaki, takes about fifty hours, and the whole run to Shanghai about four days. Thirdly, for a freight and passenger line from Vladivostok to the ports of Gensan, Fusan, Nagasaki, Chemulpo, Shanghai, Chefoo and Dalny, and return, sailings to be once in two weeks.

It is provided that the speed of the mail and passenger steamers must not be less than thirteen miles an hour, and of the freight and passenger steamers not less than ten miles an hour, and it is stipulated that the sailings must be timed to provide good connections with Russian and foreign railway and steamship lines as the Russian Government may direct. The chartering of foreign steamers is allowed. Mail steamers must have accommodation for eighty first-class, and three hundred third-class passengers, and a cargo capacity of 1,500 tons. Th e freight

steamers must accommodate twenty-five first-class, and two hundred third-class passengers, and be able to carry 1,500 tons of cargo. Russian mails, and mails from foreign ports, for Russia, are to be carried free, as well as the postal clerk to sort them, but the clerk is to be charged half the regular rate for his board. When so ordered by Russian diplomatic or consular officers, the vessels must carry free, Russian subjects found abroad in a destitute condition, but not more than five on each steamer. Freight and passenger rates are not to exceed a maximum approved by the Department of Commerce and Industry. For delay in departure or arrival, the mail steamers are subject to a fine of £5 an hour, and the freight steamers to a fine of £2 12s. an hour. If the delay is caused by inopportune acceptance of cargo, or by touching at a port not indicated in the schedule, the fine is to be doubled. For leaving a port before the scheduled time, a fine of £100 is to be imposed on the mail steamers, and of £50 on the freight steamers. The fines for omitting the whole, or part of a voyage, are respectively £500 and £250 for the two classes of steamers. If delay is due to fogs, storms, lateness of express trains, or other reasonable causes, no fines are to be imposed. Moreover, if on account of late departure from one port, the sailings from succeeding ports should also be delayed, only one fine is incurred. If the company fails twice to complete a voyage, the Government may cancel the contract, transfer the business to another company, impose a fine of £5,000, and cancel all obligation of the Government to the company.

The Russian East Asiatic Steamship Company also has a contract for a coasting line between Vladivostok and Nikolaievsk, with stops at six ports each way. Fourteen voyages must be made during the season. A speed of ten miles an hour, and a cargo capacity of 1,000 tons are required for the vessels employed, which may be under a foreign flag. Maximum freight and passenger rates are fixed, and it is provided that troops shall be carried at half rates. Government mails and couriers are to be carried free. Fines are to be imposed of £25 for a day's delay in arrival at, or departure from a port; of £50 for leaving port before the appointed time, or from omitting any port; of £150 for omitting a voyage or any part of it, and of double the amount for a second offence. The subsidies to be paid to the Russian East Asiatic Steamship Company for all these services, have been kept secret, but it is said that they amount to about £75,000 for the year. A third contract has been made with the Russ Steamship Company for a line from Vladivostok to the ports of the Okhotsk and Behring Seas, the Commodore Islands and the Chukotsk Peninsula. The steamers must have a speed of not less than eight miles an hour, and a cargo capacity of not less than 1,000 tons. Foreign steamers may be used. The subsidy in this case is fixed at £21,500 for the four voyages to be made this season, including one trip from Petropavlovsk to the mouth of the Anadir River.

HOME INDUSTRIES.

Telephone Extension.—It is often said, and not without justice, that the United Kingdom is much behind other countries in the use of the telephone. Elsewhere the telephone service is a good deal cheaper, and its use much more general. But even in England its use is rapidly extending, as is shown in the particulars given by the National Telephone Company in its report upon the business of the half-year ended December 31st, 1906, just issued. The report shows the growth year by year of the business of this great company. In 1904 its income was £738,680, and the amount of the rentals carried forward for unexpired terms, £313,979; for 1906 the figures had risen to £2,436,996 and £1,057,806 respectively. The Post Office royalties in the former year were only £67,223, in the latter they had increased to £231,848. Practically the company doubles its income every seven years. During 1906 no less than £1,129,970 was expended on capital account in the erection of additional exchange and private stations, and in the construction of underground works, the corresponding expenditure for 1905 being £974,849. The official statement is that the the new expenditure to be incurred during the next five years is to be a reproductive one, and the future policy of the company will be to spend no money on capital account which is not of this class, and "only that which will earn sufficient to pay interest and all proper charges, and yet be worth in 1911 what it will then stand at in the books." This policy is, it may be assumed, unavoidable having regard to the Company's limited tenure, much as it may be regretted in the general interest. The field for the extension of the service is immense.

Brewery Companies.—The announcement in the King's Speech that a Licensing Bill is being prepared by the Government (a Government supposed to be less friendly to the brewing interest than its predecessor) was not calculated to make investors more ready to buy brewery shares. For many years the stocks of brewery companies were among the most popular as investments, but of late, and more especially since the Licensing Act of 1904, which, under the compensation fund clause, is said to mulct the brewery companies of something like 1 per cent. on their capital, the investor has looked askance at this form of investment. For several years past the public have not been invited to subscribe to new brewery companies; and such amounts of new capital as have been offered by existing companies have mostly been subscribed for by the shareholders in the companies. There has, too, been steady depreciation in brewery stocks, partly due to the fear of further legislation inimical to the brewery industry, and partly to the general belief that the people are drinking less, and yet the profits of the brewery companies are not, speaking generally, diminishing to any serious extent. The necessary result has been a considerable increase in the net return to the investor, which now

ranges from 6¼ to per cent. to 9½ per cent. The *Economist* takes the accounts issued within the past two months of a number of brewery companies operating in different parts of the country, to show how the profits and dividends of the past year compare with those of the previous twelve months; and also how current prices and yields compare with those of a year ago. Taking fourteen representative English companies, the net profit earned by them in 1905 was £536,752, as against £525,698 in 1906, when brewery materials were a little higher than in the preceding year. The yield at the present time on many brewery stocks is exceptionally high, high enough, as it would seem, to make ample allowance for such depreciation as may arise from legislative interference with the brewing interest, and the falling off in the consumption of alcoholic liquors, consequent upon the smaller consumption per capita.

Solidified Tar.—A process has recently been patented for solidifying tar which promises, it is reported to be a commercial success. There is said to be only a loss of from 4 to 5 per cent. of the total material employed, and the product, if expert calculations are to be relied upon, is produced at much less than the cost of pitch. The inventor has sought to render tar more readily portable, and to make it applicable, at reduced cost, to many commercial uses to which at present liquid tar is unsuitable, such as replacing pitch in the manufacture of briquettes, road making, and water proofing. The process will enable a gas company to recover the more valuable portions of the tar, namely crude, naphtha, and light oils, and these can be further treated for the manufacture of carbolic acid, or used for enriching the gas made. The remaining tar can then be solidified by the patented process, and the finished material be sold locally at better prices than is obtainable for the crude tar. The cost necessary for the process is simple and inexpensive, much cheaper than the ordinary distilling plant, and quicker in operation, the whole process being complete in one day. Again, it is thought that the solution of the motor problem traffic will be assisted by this process. It is only possible to thinly surface a road with liquid tar; even boiling tar will not penetrate the surface of a road to a greater depth than two or three inches, but by the employment of solid tar blocks made by the process under review, a substantial depth may be obtained. The process enables the tar to be used in a granulated form, mixed with sand, shingle, or cement chips, and forms, when heated and pressed, a material said to be second to none for wearing surface, quite acid proof, and non-slippery. If, as is claimed for it, the solidified tar can be sold at a price that will leave a fair profit, it may be expected to have a considerable sale.

The Rubber Trade.—Although the world's supply of india-rubber in 1906, nearly 65,000 tons, mostly went into consumption, and manufacturers were busy throughout the year, largely owing to the increased demands of tyre-makers, the price of fine grades of Para, Bolivian, and Peru, showed a slight decline. No new areas of supply of much importance were opened up. The supply from the West Coast of Africa showed little change, being about 17,200 tons, as against 17,500 in 1905. Nor has there been any increase in Central America and Mexico supplies, although joint stock enterprise has turned its attention to Mexico, where, however, the Americans are said to have secured control of the most promising rubber districts. Messrs. S. Figgis and Co. give the total imports into the United Kingdom of all sorts as 21,269 tons. If these figures are correct, and Messrs. Figgis and Co. are authorities upon the subject, the imports of rubber into the United Kingdom were less last year than in 1905—21,269 tons as againstz 1,700 onst. In his book on "The Cultivation and Preparation of Rubber," Mr. Johnson gives the importation as far back as 1900, as 25,664 tons. However that may be, imports are less large than might be expected, having regard to what would seem to be the rapidly increasing demand for rubber.

Tax on Commercial Travellers.—It is not perhaps surprising that considerable irritation has been shown in this country in consequence of the imposition of the Quebec Commercial Travellers' Tax. It has, of course, to be remembered that this tax is a provincial one, not one that is the outcome of Dominion legislation. But this distinction is not appreciated by home critics. It is argued to be an anomalous state of things which permits a Government part and parcel of the British Empire to tax British commercial men visiting Canada with the one object of doing business there. Referring to the subject in his report to be found in the weekly report issued by the Government of the Dominion, Mr. Harris Watson, who is the Canadian commercial representative in London, says that "quite a few firms have stated that they are instructing their agents to avoid the Province of Quebec altogether, and almost all complain that in their estimation taxes of this description form an obstacle to the development of Anglo-American trade." It is to be regretted that the Quebec Legislature has thought it necessary to impose the tax as against the mother country. The yield from it must be insignificant, whilst the irritation caused by it is considerable.

Exports of Manufactures and Yarns.—Messrs. Helmuth Schwartze and Co. give a condensed statement of the British export of woolen manufactures and yarns, which shows in the period under review—1895-1906—an increase of nearly 10 per cent., of which about 7 per cent. was due to larger quantities, and 3 per cent. to higher values. The total is the best since 1874. The increase went principally to Germany, Australia, Canada, and South America, while China, Japan, and the United States, took took a little less.

The Carpet Trade.—There is a general impression that the British carpet trade is a decaying industry, but in its commercial history and review of 1906 the *Economist* shows that this is a mistaken view. No doubt manufacturers have been heavily hit by reason of the greatly enhanced values of all raw materials, and it is an open question whether they have even covered the cost of production, but the volume of trade was equal to that of 1905. The carpet industry is always one of the last to share in the benefits of national prosperity, as it is one of the first to suffer in periods of depression, but there was a marked expansion in the Colonial and South American demand, which compensated for the quietude, and at the end of the year there was a distinct revival in all the home centres. The Axminster trade has been the most active, but there has been a growing demand for super Wiltons. Brussels carpet remains out of favour, fashion having shifted to deep cut pile carpets, but it is thought there may soon be a revival in the demand for Brussels, and the lower grade Wiltons, said to be the most durable floor covering on the market. Unfortunately, the Axminster manufacturers have had to reckon with something like an advance of 50 per cent. in the raw materials whilst unable to raise the price of their various grades. The export trade has been good. The trade with the United States has improved, and Canada, Australia, the Argentine Republic, and Mexico have been good customers. On the Continent little has been done, and the new Spanish tariff precludes the hope of any improvement in dealings with Spain. The Canadian preference should enable English makers to improve trade with the Dominion at the expense of their German and French competitors, and the *Manchester Guardian* states that three English firms have decided to start mills in Canada.

OBITUARY.

THOMAS WHITE SMITH.—Mr. Thomas Smith, for many years the principal of the Caslon Letter Foundry, died on the 5th inst. after a severe attack of influenza. He was the son of a Wesleyan Minister, and was born at Tiverton in 1835. After six years' schooling at Kingswood, near Bristol, he was apprenticed to a printer at Newport, Isle of Wight. In 1851 he was at a newspaper office in Guernsey, where he obtained the testimonial that he was "a swift and clean compositor." After various changes he obtained, in 1857, an engagement in the counting house of the Caslon Letter Foundry. In 1865, through Mr. H. W. Caslon's dispute with his *employés*, business was suspended for eight months. Mr. Smith, in consequence, became manager of the new London branch of Messrs. Stephenson, Blake and Co. In 1873 he took charge of the Caslon Letter Foundry owing to the illness of the proprietor, Mr. H. W. Caslon. On the latter's death in 1874 he became a partner in the firm, and in the following year started the "Caslon Circular," in which for twenty-one years he wrote almost everything that appeared. In 1895 he became sole proprietor of the historic Caslon Letter Foundry. He withdrew from active partnership in 1900, and left the business in the hands of his sons. Mr. Smith was elected a member of the Society of Arts in 1880.

GENERAL NOTES.

EXHIBITION OF PERIODICALS.—An International Exhibition of Professional Newspapers and Periodicals will be held in the Exhibition Hall of the Society of Industrial Arts in Copenhagen, in May and June next, under the presidency of Sigurd Berg, Minister of the Interior. The Exhibition is promoted by the Association of Danish Professional Papers and Periodicals. The office of the Exhibition, from which information may be obtained, is Colbjprussensgade 14, Copenhagen.

MEXICO.—In his review of the trade of Mexico for 1905-6 (Cd. 2682), Mr. Reginald Tower gives figures showing an increase in the imports of no less than £4,250,000, or 23·82 per cent. on the value of the imports in the previous fiscal year, but he points out that nearly the whole of this increase arises from the imports of minerals. In most of the other branches, trade only shows a normal growth, while in the classes of machinery, dry goods and arms, explosives, &c., there was a slight falling off. The immense increase in the value of minerals imported arose from exceptional and non-recurrent circumstances, being almost entirely due to the importation of the gold coins minted in Philadelphia, and of gold in other forms, with the object of establishing the gold standard, and is counterbalanced by the corresponding increase in the amount of Mexican dollars exported in exchange. It may be noted that the product of the guayule tree figures for the first time among the exports. It is a form of cactus extract used in considerable quantities for mixture with rubber. An export tax was imposed on it in the Budget Bill, 1906-7, and it is expected that with the great demand for rubber throughout the world, the production of guayule will have considerable development.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday Evenings, at 8 o'clock:—

FEBRUARY 27.—"Modern Typewriters and Accessories." By ARTHUR E. MORTON, Examiner in Typewriting to the Society of Arts. SIR JOHN CAMERON LAMB, C.B., C.M.G., will preside.

MARCH 6.—"The Discovery of the South Eastern Coalfield." By PROFESSOR W. BOYD DAWKINS, D.Sc., F.R.S. The Right Hon. LORD HARRIS, G.C.S.I., G.C.I.E., will preside.

MARCH 13.—"Mediæval Stained Glass, its Production and Decay." By NOEL HEATON, B.Sc.

MARCH 20.—"Smoke Prevention in Factories." By JOHN B. C. KERSHAW, F.I.C.

Dates to be hereafter announced:—

"The Underground Water Supply of the Thames Basin." By CLAYTON BEADLE.

"Hungarian Arts, Home Industries and Commerce." By LOUIS FELBERMAN.

"Trypanosomiasis or Sleeping Sickness." By HERBERT W. G. MACLEOD, M.D., B.Sc.

"The Cultivation of India Rubber." By HERBERT WRIGHT, Controller of the Government Experimental Station, Ceylon.

"Aerial Navigation." By MAJOR B. F. S. BADEN-POWELL.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

MARCH 14.—"The City of Madras." By SIR JAMES THOMSON, K.C.S.I., M.A., late Member of Council, Madras. The LORD AMPTHILL, G.C.S.I., G.C.I.E., will preside.

MAY 2.—"The Applicability to Indian Rivers of the Italian System of Dealing with Silt." By SIR EDWARD CHARLES BUCK, K.C.S.I., LL.D., late Secretary to the Government of India, Revenue and Agricultural Department.

MAY 30.—"Irrigation Colonies in India." By LAURENCE ROBERTSON, I.C.S., Under Secretary to the Government of India, Revenue Department.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

MARCH 5.—"British Malaya." By SIR WILLIAM HOOD TREACHER, K.C.M.G., M.A. (Oxon), late Resident General Federated Malay States. SIR FRANK SWETTENHAM, K.C.M.G., will preside.

April 23.—"The Mineral and other Resources of Western Australia." By the HON. C. H. RASON, Agent-General for Western Australia.

APPLIED ART SECTION.

Tuesday evenings, at 8 o'clock:—

MARCH 19.—"Oils, Varnishes and Mediums used in the Painting of Pictures." By A. P. LAURIE, M.A., Principal of the Heriot-Watt College, Edinburgh.

APRIL 16.—"Joinery and Furniture Making." By A. ROMNEY GREEN. HALSEY RICARDO will preside.

APRIL 30.—"Lustre Pottery." By WILLIAM BURTON.

MAY 28.—"Sheffield Plate and Electro-plate." By SHERARD COWPER-COLES.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

F. HAMILTON JACKSON, "Romanesque Ornament." Three Lectures.

February 25; March 4, 11.

LECTURE I.—FEB. 25.—What Romanesque is—French examples—Oriental features—The portals at Chartres—Provençal developments—Direct Oriental influence in France and Italy—Norman Romanesque—Tau croziers — Fonts imported from Tournai—Sicilian Romanesque — The zig-zag—Scandinavian patterns—Spanish churches of 9th and 10th centuries.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEB. 25...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Mr. F. Hamilton Jackson, "Romanesque Ornament." (Lecture I.)

Farmers' Club, Whitehall Rooms, Whitehall-place, S.W. Dr. J. A. Voelcker, "The Fertilisers and Feeding Stuffs Act (1906.)"

Surveyors, 12, Great George-street, S.W., 8 p.m. Mr. Aubrey J. Spencer, "The Agricultural Holdings Act (1906.)"

Geographical, Burlington-gardens, W., 8½ p.m. Mr. George G. Chisholm, "Inland Waterways."

Actuaries, Staples-inn-hall, Holborn, 5 p.m.

Medical, 11, Chandos-street, W., 8½ p.m.

TUESDAY, FEB 26. Royal Institution, Albemarle-street, W., 3 p.m. Professor W. Stirling, "The Visual Apparatus of Man and Animals." (Lecture III.)

Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. Dugald Clerk, "The Limits of Thermal Efficiency in Internal Combustion Motors."

Anthropological, 3, Hanover-square, W., 8½ p.m.

WEDNESDAY, FEB. 27...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Arthur E. Morton, "Modern Typewriters and Accessories."

Geological, Burlington-house, W, 8 p.m. 1. Mr. William George Fearnsides, "The Lower Ordovician Succession in Scandinavia." 2. Mr. Cuthbert Baring Horwood, "The Occurrence of Pseudomorphous Pebbles of Pyrites at the Crown Reef Mine (Witwatersrand)."

Royal Society of Literature, 20, Hanover-square, W., 8½ p.m.

THURSDAY, FEB. 28...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Dr. W. Martin, "Old Dutch Paintings and Painters." (Lecture I.)

Optical, 20, Hanover-square, W., 8 p.m. Annual meeting.

FRIDAY, MARCH 1...Royal Institution, Albemarle-street, W., 9 p.m. Count de Bosdari, "Dante in the Critical and Poetical Works of Carducci."

SATURDAY, MARCH 2...Royal Institution, Albemarle-street, W., 3 p.m. Prof. J. J. Thomson, "Röntgen, Cathode, and Positive Rays." (Lecture III.)

Journal of the Society of Arts.

No. 2,832. VOL. LV.

FRIDAY, MARCH 1, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MARCH 4, 8 p.m. (Cantor Lecture.) F. HAMILTON JACKSON, "Romanesque Ornament." (Lecture II.)

TUESDAY, MARCH 5, 4.30 p.m. (Colonial Section.) SIR WILLIAM HOOD TREACHER, K.C.M.G., "British Malaya."

WEDNESDAY, MARCH 6, 8 p.m. (Ordinary Meeting.) PROF. W. BOYD DAWKINS, D.Sc., F.R.S., "The Discovery of the South-Eastern Coalfield."

Further details of the Society's meetings will be found at the end of this number.

EXAMINATIONS.

The Society's Examinations will commence on Monday, April 15.

The last day for receiving applications from Local Committees is Tuesday, the 12th March, 1907, and after that date none will be received under any circumstances whatever. Application forms from the Provinces should therefore be posted not later than Monday, the 11th March. Committees may, however, close their entry lists at an earlier date, if found desirable.

Copies of the Programme for 1907, with full details, together with the questions for 1906, and reports by the Examiners, can be had, price 3d. (post-free 4d.) on application to the Secretary, Sir Henry Trueman Wood, Society of Arts, Adelphi, London, W.C.

The questions for the years 1900, 1902, 1903, 1904, and 1905 can also be obtained (price 4d. each year post-free) on application as above.

CANTOR LECTURES.

On Monday evening, February 25th, Mr. F. HAMILTON JACKSON, Vice-President of the Society of Designers, delivered the first lecture of his course on "Romanesque Ornament."

The lectures will be published in the *Journal* during the summer recess.

CANTOR LECTURES ON ARTIFICIAL FERTILISERS.

The Cantor Lectures by Mr. A. D. Hall, M.A., Director of the Rothamsted Experimental Station, Lawes Agricultural Trust, on "Artificial Fertilisers: their Nature and Functions," have been reprinted from the *Journal*, and the pamphlet (price one shilling) can be obtained on application to the Secretary, Society of Arts, John-street, Adelphi, London, W.C.

A full list of the Cantor Lectures which have been published separately, and are still on sale, can be obtained on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

Thursday afternoon, February 14; THE RT. HON. LORD CURZON OF KEDLESTON, G.C.S.I., G.C.I.E., in the chair.

The CHAIRMAN, in opening the meeting, said that although he was at present taking no part in public affairs, he could not resist the invitation, which he regarded almost as a command, to be present and introduce the reader of the paper. Sir Frederic Lely was one of the most eminent civilians who had served the Government of India in recent years, distinguished both by the eminence of the posts he had filled and by his notorious sympathy for the people. Rising through the various grades of the Bombay Administration, he was Commissioner at Ahmedabad at the time the terrible famine of 1899-1900—about which he was chiefly going to speak—fell upon the rich province of Gujerat, of which he was the head. How Sir Frederic administered that famine the audience would be able to gather from the paper, modest as it was certain to be, that would be read. It was partly in recognition of his work in that famine that he (Lord Curzon) had the pleasure of inviting him to be a member of the Legislative Council at Calcutta, and later, before the termination of the author's career in India, he made him the head of the Central Provinces. Such were the record and the credentials of the distinguished man who was to read the paper.

The paper read was—

THE PRACTICAL SIDE OF FAMINE IN INDIA.

By Sir Frederic S. P. Lely, K.C.I.E., C.S.I.

As the subject of Indian famine has been already treated on two occasions before your Society, I wish to make it clear that I make no pretension to occupy the ground already covered by the ability and knowledge of Sir Charles Elliott and Mr. Holderness. I only take up the subject because my point of view is different from theirs. They discussed the broad problems of famine policy as they appear from the watch-tower of the Imperial Government. I essay the humbler task of giving some reminiscences of one who was down below in the thick of the fight. Anyone who makes a study of, for example, the great Mutiny, its causes, progress, and results, will, of course, go first to the comprehensive pages of Kaye and Malleson and others, but he will be all the wiser if he adds to his reading such books as the narratives of Lady Inglis and Sergeant Forbes Mitchell. And so I venture to hope my words, though limited in their scope, may have their use in bringing home to you the anguish of famine.

We often hear of invasions of India over the North-West Frontier—of how successive hordes of foreign soldiery have poured down upon its plains to conquer or destroy. But perhaps it is not realised so clearly by those who have not lived in the country that every year there is an overwhelming invasion from the south, which is not feared but welcomed, for it brings not havoc and death, but food and courage to an exhausted land — it brings water, which, in a tropical country, more than wine, "maketh glad the heart of man." The Hindu, who deifies everything, would say it is the advent of the storm-god Indra, "whose mantle is the sky, whose jewels are the stars, whose chariot is a cloud, and who rides on the wings of the south-west wind." The matter-of-fact Englishman is content to call it the monsoon wind driving the moisture-laden clouds over the land, from the southern sea. You will forgive me if, in order to round off my story, I briefly recount what happens, though to many it must be already familiar. After the month of September, there is little rain in the centre and north of India, and after March the land becomes intensely hot. This rarifies the atmosphere, and thus a current of wind, laden with moisture from the sea, is drawn in and gradually established, from south to north. It breaks first upon the island of Ceylon, and thence passes on to strike against the Ghauts, where the colder temperature of the hill sides condenses the vapour into heavy rain. At first, the mountain range is too high to be surmounted, and so the clouds pass on northward, leaving the greater part of the Madras Presidency, to the east, high and dry. As the mountains get lower, they spread to the other side. The valleys of the Tapti and Narbadda are gateways through which offsets pass into the centre of India, but the main body pours itself over Gujerat, one of the garden provinces, and onwards, over the dry plains of Rajputana into the north, where its advance is blocked and diverted by the great barrier of the Himalayas. Sindh is left out altogether. No rain falls there throughout the year except occasional showers, and the province would be a desert but for the Indus, which, in the heat of the month of March is flooded with melted snow from the hills, and spreads itself over the country in a network of canals. What the Nile is to Egypt the Indus is to Sind. But Nature's programme is not yet finished. We left the remaining mass of rain-cloud banked against the Himalayan Mountains, where it is finally exhausted in rainfall, making fertile fifteen hundred miles of country up to the jungles of Assam. But a large corner was left aside by the incoming monsoon, and the rest of India being now supplied, a wise and beneficent Providence completes its scheme by arranging for that. A reverse action begins. As the sun goes south in the latter half of the year, the land of Upper India becomes cooler, while the sea retains much of its warmth. Consequently, a backward current of wind is created, and that portion of it which passes over the Bay of Bengal absorbs moisture from it, which is precipitated on the fields of Madras. If everything is normal, it goes almost like a well-managed railway system. I lived for some years in the city of Ahmedabad, and we used to look out there, towards the end of May, for news of the arrival of the monsoon in Ceylon, and when it came, we expected the rain at our own gates in just about three weeks. In many years, however, there is some little hitch, some deflecting influence which we cannot, at present, understand or foretell, which upsets the distribution and causes too much rainfall here, and too little there; a flood here, and a drought there.

Now, every one who has lived through the

year in the plains of India must have a vivid memory of that time of suspense, at the end of the hot weather, when the world is waiting for the rain. For the last three or four months the pitiless sun has been beating down on the land turning it all to a monotonous brown—scorching, cracking, pulverising. The hot wind, like a blaze, has been whirling the dust into every wrinkle and crevice. Outside, every stone is too hot to touch; inside the tent-or house—even the chairs and tables, covered with grit, feel to the hand like the floor of an oven. The mosquito has become a burden, and the cattle peering about in the withered fields for their daily food grow weaker and thinner. The whole of Nature gasps. Men whisper to their neighbours, "When will Meghji (the rain-god) come? Has he reached Ceylon? What news from Bombay"? When he does come, especially after being long delayed, a sigh of relief goes round as men realise that once more the great crisis of the year has been passed. There is no better music on this earth than the splash of the rain, and the running of the gutters after a prolonged hot season. Sometimes it does not come, and then we have, enacted on the stage of real life, the tragedy of famine.

We hear much of approximation between East and West, of the sympathy which ought to exist between Englishman and Indian. Many look to social intercourse as a means of obtaining it, and they are right, so far as they go. But I have chosen the subject of this paper in the belief that if we could enter into the monsoon experience of our fellow-subjects—into that if no other—we should get nearer to them than by months of superficial contact. It has exercised as deep an influence upon their life and character as, *e.g.*, our insularity has upon ourselves. The frequent want of what we call pluck, so often remarked in the Indian, may be partly explained and excused by it. The vigorous Anglo-Saxon belief that man is master of his own fate, sounds a mockery to people whose very existence depends every year at a certain season on the coming of a wind that bloweth where it listeth. Until the British Government came and took famine by the jaws, there was nothing for the humbler and weaker Indian, on a failure of rain, but to sit down and die, as he did every other year in one part of the country or another under native rule. It is little wonder if the cumulative effect of many such failures has been to diminish self-reliance and power of initiation.

However, that is by the way. Before the year 1899, in the province of Gujerat, to which I wish particularly to invite your attention, the people were generally well fed, and lived in comfort, on a fertile soil. Including minor Native States, the area is nearly 34,000 square miles and the population about 5½ millions—considerably larger in both respects than Scotland, though only a fraction of the great famine tract under the Government of India. It is recorded that in the two years 1828 and 1829, part of the Government share of the land-rent was remitted, not because of the failure of the crops, but because of their abundance, in consequence of which, and the impossibility of conveying to distant markets, grain was unsaleable except at nominal prices. When I first knew the province the effects were still visible of the inflated prosperity of the time of the American War, when the price of country cotton went up from fourpence per pound to two shillings, and when cultivators, having no use for their unwonted wealth, had the clamps and tyres of their field carts made of silver, or indulged in the luxury of an extra wife, or employed labourers instead of working with their own hands. They had to suffer when the reaction came and found them with a higher standard of expenditure and reduced incomes, the consequence of which was general indebtedness, but still the poorest had enough to eat, and the masses more than enough. Men who came from other parts of India were struck with the well-fed and indolent Gujeratee as compared with the frugal and laborious Maratta. I remember the amusement of an Indian gentleman, who had come from the Deccan to live in the town of Broach, at finding that many of the lower classes required their early morning tea. There had been no serious famine among them for a century, and they only knew of it as a grandfather's tale. To such a people it was a terrible shock, when in 1899 the month of June passed into July and that again into August with practically no rain. It came up the coast as far as Bombay, and then under some occult influence it dwindled off into casual showers, leaving the great region of Central India down to the west coast to lie as a desert, instead of, as it usually was in July, a green garden.

With one consent the eyes of all were turned to their first line of defence—the gods. Wealthy men employed Brahmins to say prayers in the temples. Parties of women day by day drenched the emblems of their favourite deities with

water, to indicate in the clearest possible way what they wanted. The mayors of the chief towns walked in procession round the walls, stopping at every gate to pour out libations of milk, and winding up with that most indispensable of religious ceremonies, a feast to Brahmins. In the villages, on a fixed day, the people left their houses in a body and cooked their food in the fields outside. The significance of this I take to have been that the rain-god apparently desired to lay waste the land, and it was hoped he would accept the deserted village as a substitute. "You wish to make bare our fields, take our empty houses instead."

By the end of August the people began to realise it was all of no avail, and to turn their eyes to their last hope—the officers of the British Government. Already the first sign of approaching calamity had made itself visible, viz., wandering people and wandering cattle. It may sound cynical, but it was as important to save the cattle, as to save the men and women, for on the former depended the future livelihood of the latter. The cultivator's plough and cart were drawn by oxen only. The cows supplied even the poorest with whey, if not with milk, which was the only form of animal food permissible in a country where eating meat is a sin. It was pitiful to see the frantic efforts of the poor folk to save their cattle. They searched about in the corners, and on the waysides, for straws and sticks—anything that could be masticated. They tore the thatch from the roofs of their houses. They climbed the trees, and picked off the leaves one by one, so that to the brown fields, and hungry vagrants, and wandering cattle, was added yet another presage of mighty famine, viz., lines and groves of skeleton trees stripped of their green foliage. The official weekly return of deaths was compiled by clerks, whose knowledge of English was often rather scanty, and about this time, in the column of "Causes of Death," there appeared a new disease, called "trefal," which was puzzling until it occurred to one that it was meant for tree-fall, and referred to unlucky persons who had climbed in search of leaves for fodder, and had missed their hold and fallen. Every week, for more than a month, "trefal" continued to account for three or four deaths—the first victims of the famine that was now closing its grip upon us. We were face to face with a series of grave problems. There were roughly two million head of cattle with practically not a blade of grass nor a wisp of hay to feed them on. For it was not the custom of the country to store hay. So secure did the people think themselves that those who happened to have a surplus in the month of June sold it off for export, to their bitter regret a month or two afterwards. With the railways at command it was comparatively easy to bring in grain to feed the people, but to supply the needed grass was not so easy seeing that every full grown animal would eat up two truck loads before the rainy season again came round. Grass, however, was to be had in the forests of Thana, two to three hundred miles away, and so it was arranged that as soon as it was ready for cutting, at least one train per day should be loaded with it. Meanwhile, another experiment was tried. It was said "As well as bringing grass to the cattle why not take the cattle to the grass? In the forests of Thana there is plenty of pasture land; the trains are pouring in with grain and fodder, why not utilize their return journey to carry back selected animals?" It was not so easy as it may seem, but we got to work, arranged for reduced railway rates, and placed the forest pastures in charge of a vigorous Englishman, Mr. Wood, of the Civil Service, who undertook to look after the cattle on arrival, to get them registered, to provide them with water and fodder on their way from the stations, and to allot them grazing grounds. But the first real difficulty arose at our end; the people would not on any account let their cattle go. The rumour passed from mouth to mouth that it was all a device of Government to get cattle to ship to Africa, for the Boer War. "What the English really wanted was beef for their soldiers, and oxen to drag their waggons in the Transvaal. It was all very well to talk about the forests in Thana, but once the cattle were shut up in the train, they would never be seen again." I was encamped near a railway station in the district of Broach, when word was brought that a lot of animals that had been collected to send off, had been carried back by their owners during the night, and so to end the deadlock somehow a meeting was called. They came, hundreds of shrewd weather-beaten men very friendly, but very doubtful. So much interest had never been taken in their cattle before, and there must be something behind it. Finally, it was agreed that a dozen animals should be sent by way of experiment, and that two of the farmers should

go along with them and see what become of them. It reminded one of the Israelites sending the spies into the land of promise, and like the spies they too returned bringing back word that the land was good, and that the Englishmen there evinced no special desire for beef. They also brought with them not bunches of grapes but bundles of grass to prove the quality of the pasture. From that day difficulty No. 1. was at an end, and far more animals were offered than it was thought prudent to send. Another trouble will illustrate how hard it is for East and West to meet even on the lines of charity. The prevailing religion in this part of India is the Jain, the leading tenet of which is the sacredness of all animal life. While in theory, the life of a beast is as valuable as that of a human being; in practice, it has become more so. As a matter of daily conduct, it is as great a sin, or a greater, to kill a flea as to kill a man. This popular sentiment found its expression in ordinary times in the maintenance by the wealthier merchants of asylums and hospitals for ownerless and decrepit animals. Now, recognising that we could at the best only save a fraction of the people's herds, we carefully selected the most valuable—the most worth preserving. The merchants, on the other hand, doubled and trebled their subscriptions to their own fund, and chartered trains to carry away to the pastures, not the best, but the worst, actuated by much the same feeling as would lead us to rescue first from a burning house the most helpless of the inmates. The rolling stock was limited, and the railway would give us no preference because the merchants were in prosperous times their best customers, and hence we often had the mortification of seeing scores of trucks depart, loaded with refuse animals, many of whom died on the way, instead of young and strong stock, which might have come back at the end of the season to help the people to regain prosperity. However, at last about 10,000 head were got off, Government lending the money to pay the charges. But it did not turn out a success, the main reason being that the Gujerat cattle, like their owners, were soft and little used to roughing it. The rocky ground, so different from the sandy plains of their own province, worried them; the coarse, unaccustomed grass of the hills did not nourish them; and the water did not suit them. Their own herdsmen, who knew their ways and whose care might have softened their lot, also disliked the foreign country and ran away. So that in the midst of a rough plenty they died by hundreds. Not more than 40 per cent. ever came back. The conclusion was, that if similar conditions should ever recur, it would not be advisable to deport the cattle but rather, at any cost, to keep them at home under the personal care of their owner. It is only a phase of what I believe to be an elementary truth in Oriental government — that in dealing with famine, or plague, or any other trouble, that policy has the best chance of success which preserves intact the family life.

In the month of December the dry grass began to pour in from other provinces, and the question was how to distribute it. If we sold it the danger was that large quantities would get into the hands of the rich merchants, who would use it to feed the animals that were not worth keeping, whereas, we only had enough to feed a comparative few, and we wanted them to be the pick of the country. So it was decided to establish cattle camps where only young and well-bred animals were taken in and fed under our own control. The experiment was a novel one, and it is not surprising that we made mistakes. The first camp was a failure. The animals admitted were already too run down to digest the foreign grass, and most of them died. We had come to see that it was out of our power to save even a large fraction of the two millions in the province, but the breed was a fine one, admirably adapted for the deep sandy soil of that part of India, and so the able Director of Agriculture, Mr. Mollison, set himself to the more limited task of saving it from practical extinction. Those cultivators who could get any fodder at all were inclined to save their oxen as being of more present value, and to let their cows die. So he took in chiefly cows, well-bred, young and strong; he limited the number in each camp to about 300 to allow of close supervision, and he gave them a daily ration of oil cake to supplement the innutritious grass. In the end in these camps, besides oxen, several herds of cows and a number of sires were saved—about 9,000 head in all—who formed nuclei for repairing the loss of the famine. Without these it is tolerably certain that the famous breed of Gujerat cattle would have disappeared. It was not a colossal achievement, but it was worth doing. The work was extended and made permanent by the munificence of Lord Northcote, who gave Rs. 25,000 for the purpose of establishing a central farm for the study of cattle and dairy farming.

The management of the camps made us acquainted with qualities in the Indian cattle we had never suspected. The truth is the Indian cow and ox have a much better chance of developing character than those of other countries. The cow has, you are well aware, for many centuries been esteemed as the holiest of animate beings. To kill a cow is an unspeakable sin. A very popular religious print represents a departed soul at the river of death getting safely across by holding on to a cow's tail, while others, not so befriended, are torn by terrible fishes. The Brahmani bull has the freedom of his village. The cultivator's ox, too, is treated as a member of the family. He occupies as good a room in the house as his master On gala days he is painted with red, decorated with flowers, and fed with grain and spices. Now, if environment goes for anything it is not surprising if, after centuries of this human treatment, the domestic cattle show some signs of "clubbable" qualities. When the first camp was started, one of the rules drawn up by a European expert was that the animals should be sorted according to size. If big and little were enclosed together, it was thought the little ones might get the worst of it. But it was soon discovered that the bond among Indian cattle was not their size but their village. If they belonged to the same "set" they knew one another and kept the most perfect order. They obeyed the herdsman's voice and even the crack of his finger, and so far from hustling the little ones they took care of them. On one occasion, in the camp already mentioned, their good manners were sorely tried. It was the first day on which a basket of oil-cake was brought into the enclosure. They were taken off their guard, and with one consent they rushed at the unfortunate man who carried it, and knocked him over in their eagerness to get a piece. But a very short time was enough to bring them to a sense of propriety, and it was a pretty sight in after days to see them at the appearance of the basket range themselves in an orderly row, each one awaiting his or her turn. One incident I should hesitate to mention if it had not come to my knowledge on the best authority—an eye witness whom I entirely trust, though I scarcely expect others to do so. In one camp in the Panch Mahals there were several sick animals who were set apart and fed with special food which some of the others saw and coveted, and in order to get it themselves they lay down and shammed to be sick also.

As there was still a surplus of grass we began to sell it to *boná fide* cultivators at cost price, viz., Rs. 10 per 1,000 lbs., roughly about £2 per ton. By May it was recognised that the situation had entirely changed. All the useless cattle had now died and so been eliminated. None remained in the hands of private owners, except the very best which the more well-to-do had strained every nerve to save. In most cases they had now come to an end of their resources, and from every side the cry arose that they must give up the struggle unless help was given them to tide over the last two months before the expected rain.

An appeal was made to the Committee of the Mansion House Fund, and they liberally authorised us to buy up all the available stores of grass and re-sell it to genuine cultivators at an almost nominal price. More than once I stood at one of the depots, among the people flocking in with their carts, some from a distance of fifty miles, to get the precious fodder, and explained to them in their own language how their brothers and sisters in far-off London, fellow-subjects of the great Queen, had heard of their trouble, and had sent money out of their own purses to help them. If any subscribers to the Indian Famine Fund of 1900 had been present it would have done them good to see the care-worn faces light up in response. I felt that here was a bond of Empire more real and more lasting than even Bismarckian blood and iron.

I must now pass to the saving of the men and women. You will remember that they almost all lived on agriculture. Barring a few mills which exported a little cloth and yarn, the harvest of the year was the one source of wealth. I ask you to imagine the state of England if next year, not only the land were turned into a barren desert, but if every factory and mine were closed. It is not surprising that by the month of April there were over a million dependent on direct charity for their daily bread. They included at one end some smaller yeomen, and at the other end wild hill-men who fled into their huts like rabbits at the sight of a white man. Among them were men who were too proud to come to work, others who were too timid, others who were too lazy; women of good birth, who would rather die than show their faces or beg; sick people, old people, young children whose parents could not support them, or had deserted them, or had died and left them orphans—a great variety of sorts and conditions. It was clear that no one system of relief would suit them

all, and I will describe in a few words the efforts that were made under the orders of the Government of India for each particular class. The fundamental principles laid down by Government, and on which they elaborated their system were (1) that no able-bodied persons should receive food, except in return for a fair amount of work done, and (2) that no one should be allowed to die of want. Hence the first step was to open at convenient centres, earthworks, such as embankments for a new railway or excavations for storing water—the men to dig, the women and bigger children to carry. The amount of daily food necessary to keep a man, woman, and child respectively, in health was ascertained, and the money necessary to buy it at the price for the day of the local shops, was taken as the standard wage. Similarly, the amount of digging and carrying that could be done in a day was estimated and exacted for the full wage; and, on the best-managed works, measurements were made every evening and paid for on the spot. But the supervision, so as to avoid waste of public money on the one hand, and underfeeding the people on the other, involved minute and incessant care. So many cubic feet might be a fair task so long as the digging was in loose and sandy soil, but if it passed into stiffer soil without being noticed by the official in charge, and the same quantity was still exacted, the worker was overtaxed and began to run down. If wages were not paid punctually he might have to go without his food, or he got it on credit, which meant that he got less. Or if prices in the local market went up or down, and the rate of wages were not promptly raised or lowered accordingly, he got less or more than he needed. Then again, as an instance of the continuous conflict of wits between relievers and relieved, it was found that most people came to the work on empty stomachs and so a rule was made that they should be given a square meal before setting them to do any labour. Many vagabonds at once took advantage of this by appearing late in the day, getting their meal and then slipping off next morning and walking to another work to do likewise. A responsible superintendent was placed over every work, but our chief reliance was on the Famine Officer, generally an active Englishman, who was placed in charge of an area about equal to half an average county. His business was to ride about everywhere and keep his eyes open. If he found people starving at home or on the roadside, he was to find out why they did not go to the Government work. Was the fault in themselves or in the work? If the people on a work looked feeble and running down, if the numbers on a work dwindled, if the people flocked to one more than to another he was to find out the reason. If a large proportion of the workers failed to do the daily task and consequently did not earn the full wage why was it? Was the task too heavy for the average person, or did any negligence of the staff prevent their beginning in good time in the morning, or were the people only playing with the work, not being in real need of it? If he found men or women on a work so sick or weak that they ought to be in hospital, if relations and friends instead of being grouped together were harshly separated, if new-comers were not promptly taken on, if the food in the shops was bad or overcharged, he was to interfere at once and set things right. If the work was not large enough for the numbers needing relief, or if the staff was insufficient or inefficient, he had to report to superior authority. In one case it was discovered that by an official blunder the rate of wages was based on the price per lb. of husked rice instead of unhusked; in another, that worn copper coins were being issued from the Treasury for the daily wage on which the shopkeeper charged a discount. Both these mistakes made all the difference between enough to eat and not enough. On some works five to ten thousand people were employed, besides their young children and other dependents, and it will be easy to see that the task of holding the balance between their needs and the claims of the public purse was no light one. A slight oversight, a slight error of judgment might in a few days do irremediable mischief. For one grim axiom we have learned in the study of recent years is that in the administration of famine relief there is no room for atonement. If mistakes are made and the people once allowed to run down there is no getting them up again. The depressing surroundings, the exhausting nature of rigid and unaccustomed toil, the monotony and inferiority of famine diet, all prevent the recovery of tone that is once lost; and the only way of bringing a population through a famine with success is to keep up from the beginning their courage and vitality, and never to let them lose heart.

So much for those who were able to work.

But in almost every household there were many who were not able to work—young children, weakly women, elderly or invalid relations. The question was, and indeed is still, unsettled what should be done with them. The course most congenial to the people would have been to let them stay at home and to feed them there while the ablebodied went to work. It was thought wiser not to allow this, but to build huts for all near the works and to make a daily allowance to the house fathers for every member of the family unable to earn a living for himself. I doubt if we entirely realise the distress of the people at having to leave their roof-tree and their village. It was said to lead to immorality. It certainly disrupted family life. The more respectable a man was and, therefore, in a sense the more deserving, the more he shrunk from it. On the other hand, a fair and honest distribution of relief whether in food or in cash to those helpless people in their own homes scattered in thousands of villages, would have been far beyond the power of a limited staff. There would have been negligence, favouritism, and peculation, and the whole machine would have got out of hand. Not only so, but it was found by experience that if families were allowed to stay at home the fathers and elder brothers stayed also, preferring to half starve on a share of what the others got rather than go and do a hard day's work for themselves.

Far more difficult to deal with was the large floating population—immigrants from Native States and men and women who were too indolent or too timid to go to the Government works, who stayed at home until hunger drove them forth, and then wandered blindly off they knew not whither, growing weaker day by day. An extract from a demi-official letter from a district officer, describing a very common incident, will illustrate the difficulty:—

"I was riding this morning when I saw a woman with an infant, who, when she saw me, crept behind a hedge. I rode up to find her in almost the last stage of exhaustion from want of food, and went on to the nearest village for a litter and bearers. When they came the woman was nowhere to be seen, and it was not till after ten minutes' search that we found her in some bushes to which she had crawled in the hope of escaping us."

For these wandering people poorhouses were provided at the chief centres, where the starving were taken in and fed, and all such as had any strength in them were drafted off to the nearest work. Among them were of course found the most worthless of the community. So long as they were allowed to stay in the poorhouse and get their daily meal they gave no trouble, but when sent to work they at once escaped and drifted back into the streets, where they begged from door to door, gradually losing flesh until they lay emaciated and moribund. Our hold on this class was much weakened by the indiscriminate charity of the townspeople. It is a sign of piety in India to give to everyone who asks. Most persons, of course, do not attain to that high pitch of virtue, but the object of all religious men is to spread their charity over as wide a ground as possible. The sugar-cane grower when he gives a dole of molasses to every religious mendicant in order to atone for the destruction of insect life in his mills, makes no distinction between Hindu and Mohammedan. At a place of pilgrimage large numbers of beggars congregate, and a pious person instead of giving a handful of corn each to a few, passes down the line giving two or three grains to each and everyone. The object in both cases is the same, viz., to avoid the risk of offending anyone, for the curse of even one is held to be more potent than the blessings of many. I remember a man who lived near to me at one time, and who impressed me much with the crowd of poor people who assembled at his house every Sunday morning to receive alms until I learned he gave to each a coin equivalent to half a farthing. Now, it will be understood what a trouble such people were by dealing out driblets of food, just enough to keep the lazy from honest work but not enough to keep them in health. A frequent annexe to the poorhouse and often to the relief work was the orphanage. I am free to confess that Government never succeeded in this branch of relief and never will succeed. Given a stout and sturdy child who can eat his daily ration, and the official agent will keep him going, in a way, but given a wasted famine starveling, and nothing will save him but such care as cannot be bought. The devoted Christian women missionaries who sought out wretched little ones and mothered them back to life, deserved, as they gained, the gratitude of the people.

There still remained lurking in their houses people who had to be sought out and saved in spite of themselves. Some remained out of sheer timidity or obstinacy, reminding one of animals who will not move when the stable takes fire. Others were sick or crippled and had no friends to move them. Most pitiful of all were women of higher rank who had nothing

to live upon, and who were willing to die rather than incur the disgrace of showing their faces in public or taking open charity. You are aware that the family life of these classes is wrapped in secresy. If one were conversing with a native gentleman and took occasion to enquire after the health of his wife and family he would take it as an insult, for an outsider is not supposed to know of their existence. You will understand how careful the district officer had to be in selecting agents to search out these sensitive people and to save them from starvation without wounding their feelings. For the men of this class the latest Famine Codes provide that they shall be employed as clerks and overseers on the works, but this is not always possible. By way of experiment special works were set apart exclusively for them, but without much success. People, too, who though not of social rank, were unaccustomed to manual toil, suffered much. In one part there were many graziers on the works. Every family of them was, before the famine came, the owner of perhaps a hundred head of cattle—some more, some less—and earned an easy and leisurely living by making butter and breeding stock. Some of the male folk had taken the animals and gone off in the vague hope of finding a land of plenty, but no word had come from them, and the chances were that neither man nor beast would ever return. Those who remained behind, having spent all, were driven to break up their homes and come to relief works. They had never done a day's manual labour in their lives, and their blistered hands and hopeless, yet patient faces, could not but evoke pity. It was only their splendid constitutions, built up in the fresh air and on nourishing food, that saved them from dying, as so many did, from the mere shock. Artizans, chiefly weavers, were another class on whom the burden fell more heavily than on the ordinary day labourers, who chiefly sought relief, and also when engaged in the finer industries, the rough work of digging was said to unfit them for reversion to their proper occupation by blunting their sense of touch. Here again the missionaries did good service by supplying yarn to weavers at the cost of private charity, and taking back the woven cloth.

The climax of the year was reached when word came in from many points that cholera had broken out. I doubt if the fear of cholera, as a year of famine wears on into the hot months of April and May, can ever be removed, for the two predisposing causes will always, or nearly always, be present—bad water and deficient vitality in the people. It is a matter of common observation that the victims in an epidemic of this disease are mostly persons whose nervous powers have been already enfeebled either by ill-health, or by fatigue, or by panic. Dr. David Wyllie, once a well-known member of the Indian Medical Service, used to be fond of telling how in a cholera year he paraded all the prisoners in the jail when they came in tired from their morning's work and dealt out to them an allowance of grog, and how not a man got ill except one who was found on inquiry to have been absent from the parade on the day of his seizure. Every layman even, who has seen much of cholera, knows that those who keep up their spirits are most likely to recover. Hence what could be easier prey than a crowd of Indians gathered away from their homes at the end of a year of grinding famine? Everything combines to depress a people whose inclination at the most cheerful time is to succumb to any attack. The famine officer has not to fear "bread riots" but the very patience which makes the people easier to handle at first, recoils against him when a wave of cholera passes and the problem is to brace them up. Often the subordinates from the native medical officers to the menial servants stick manfully to their posts but sometimes they do not. More than once in 1900 the higher officers were left almost alone to deal with camps of dead and dying.

As the month of June approached the winding-up began. It would require another hour to tell how the people were got back to their villages and helped until the new crops were ready; how Mr. Mollison devised a light plough for draught by men; how cattle were supplied from Central India on behalf of Government, but still more by private enterprise; how enormous loans were made from the Treasury to enable the farmers to buy not only cattle but seed and labour; how the Mansion House and other private funds came in to set up again many a broken man. Unhappily, too, for Gujerat, the story would not be conclusive, for, owing to insufficient rain, followed by rats and locusts, the season of 1900 was little better than that of 1899, with the important exception that the early rain was sufficient to produce fodder. I, therefore, pass on to make, in closing, two or three general remarks.

This paper may perhaps suggest to some a more vivid conception of what famine

still means, especially in a province like Gujerat, where the people have not, like those of the Deccan, developed famine-resisting qualities. The steady routine of the relief work bears hard on the man who usually worked when he pleased and how he pleased. The ration of imported food, the same from day to day, is a poor substitute for fresh vegetables and milk or whey and home-made bread to which he was accustomed. I do not know if there is any physiological explanation of it, but it is an undoubted fact that natives of India are more sensitive to changes in diet than Europeans. If the question is asked in the villages what the people died of in the famine year, the most usual reply is not "want of food," but "they died of eating the train-borne rice." An Indian friend of mine speaking of this said, "Yes, it is quite true; I can afford good food, and yet whenever I go to see my brother in Bombay, who eats rice from Burma, I get unwell." Another said, "A large number just above the lowest class did not die of hunger but of nervous collapse." A cultivator's savings for the most part at such a time, so far from being a help, were a drag upon him. If he had any money to spare in good times he never put it in the bank. He might lend some to his neighbour, who in time of famine only made of it a further claim to be kept going. First of all, he would lay it out in the purchase of oxen or a cow. The leading men in good times would make a brave show of cattle—several pairs of oxen, a few cows and calves, and a pony to ride; bnt in time of such famine as that of 1899 they only meant so many more mouths to fill.

The second note is that famine relief has grown into a special study. During the last thirty years or so India has had many visitations, each of which has been utilised by Government to gain and garner experience, and each of which has left them better equipped for fighting the next. Their famine codes lay down beforehand with consummate generalship the plan of campaign—affixing the responsibility for watching in ordinary times the condition of the people and suggesting means of improvement, for detecting and reporting the danger signals as soon as they appear; providing for estimates beforehand of the number and classes of persons who may require relief in case of famine, and for maintaining programmes of suitable works with plans and supplies of tools; authorising and ordering prompt increase in the district staff, including doctors and police; the suspension or remission of Government revenue; the adaptation of methods to the various classes according to their physical powers and position in life; the early organisation of gratuitous relief of those who cannot work; the utilisation of voluntary private help; and generally with minute foresight setting aside routine and red tape without relaxing real control, and ensuring co-operation among all concerned. How new this branch of economic science is may be gathered from the fact that in the ninth and tenth editions of the *Encyclopædia Britannica* thirty-nine columns are devoted to the confused and unscientific system of English poor-law, while not a word of mention is given to the carefully devised system of Indian famine relief.

In Gujerat the one alleviation of famines under native rule was the storage of grain by the small landlord whose practice it was to fill a pit with the surplus of every good year. This is the oldest method of fighting famine in the world, and it is superficially so natural that many still advocate a reversion to it. To begin with, it is impossible to carry it out on so huge a scale as is necessary to make it really effective. Probably nowhere in the continent was the custom so established as in Western Gujerat and Kattiawar, where in some villages there were as many as ten or a dozen pits at a time representing as many years. Yet in that very area there are early records of parents eating their own children. There is, too, the risk of deterioration in the grain; there is the certainty of loss of interest on the value. In the days when the science of locomotion was but little advanced there was much to be said for it, but in these days the ideal of Government is, and should be, not to bury the surplus in the earth or in a warehouse, but to invest it in irrigation, in railways, in agricultural improvements. So far as it is necessary and prudent to retain the harvest of one year against the possible deficit of the next, experience has shown that it is safe to leave the business in the hands of the private dealer who would only be discouraged and embarrassed by the collaboration of Government. The corner stone of modern relief is easiness of transport. It has been pointed out that the invention of printing, much lauded though it is, would have been of little value to the world if it had not been accompanied by the invention of paper; and just so the modern famine policy would have been futile without the introduction of the railway. At the first

signal of a failing harvest the telegraph is set to work, and in a few days if need be, train-loads of grain pour in, the rising prices fall, and "there is corn in Egypt."

Meteorological enquiry has not yet laid bare the causes which deflect the rain current and produce famine. Some day it will. Meanwhile a theory which by means of iteration and re-iteration has gained some measure of assent, is that which assigns the recurrence of famine and the disaster it entails, to the administration of the British Government. Annually our friends in Congress are promised in a peroration from the Presidential chair that when all power passes into Indian hands famine shall be no more. I can only at this moment refer briefly to the report made by Colonel Etheridge in 1868. If his enquiry into past famines had been deferred until only a few years later, the whole truth would not have come to light, for the native rulers often thought so little of famine that they neglected to record it. In 1868 there were still old men alive who remembered what they had seen or heard of olden days. Authentic evidence was gathered of 16 distinct famines in one or other part of the Bombay Presidency between 1770 and 1825, while between 1825 and 1868 there had been nothing to justify the name except in the native State of Cutch, on the borders of a rainless desert. One of the witnesses said, "It makes one tremble even at this day to think of what happened"—grain selling at a rupee per pound, girls selling at eight annas apiece, villages depopulated to this day, and fathers eating their own children Charitable people opened cheap grain shops, but the weak were not allowed to profit by them, being elbowed out and trampled down by the stronger. One of the worst of these famines occurred in 1847 according to the Indian calendar, 1791 according to ours—and to this day a popular oath in the districts affected is "May all the sins of '47 rest on my head if I speak not the truth." The bonds of government and of society were broken, and in their hunger and despair men "feared not God, neither regarded man."

It is true that famine does connote a difference between past and present. It has ever existed, but it once meant abandonment of the people, desolation, cannibalism. It now means much distress, much mortality, it is true, but also persistent and thoughtful effort to diminish it, approaching by dint of severe experience ever nearer to the ideal when everything shall be foreseen and forestalled. I am not of those who think the work of England in India is done or nearly done. To affect that it is and to shirk our burden before the time will not be magnanimity but indolence and cowardice. If Englishmen and Indians will to themselves prove true and to one another, the golden age is not behind us but in front. Part of it will be this new gospel of famine relief, the object of which does not begin and end in keeping down the Bills of Mortality. It appeals to, and desires to enkindle, a sense of the brotherhood of man and the worth of human life—a sense which is at present almost non-existent in the East, being stifled or perverted by Caste. It seeks to organise pity, to codify self-help against the forces of Nature. It brings men side by side in a life and death struggle, and strips them so far as is possible of the adventitious differences of race and education. It welds them together in a fire of common trouble and a common task. With the memories of those sad years are blended the faces of many faithful men who spent themselves without stint, but especially of five who, it is safe to say, were the first in the history of the province to give their lives to save the outcasts — the outcasts and aborigines—who still to Brahminical feeling are something less than dogs. There was Maneklal Narbheram, who went a healthy vigorous man to the Wagra tabula of the district of Broach, and for six months never spared himself night or day, and then returned, a wreck, to die a year afterwards. A brave and steadfast man who knew what was before him and did it. There was Mulligan, Presbyterian missionary, who when the head of the district was in sore need of strong men volunteered to help and was put in charge of a thousand persons on a relief work, on whom cholera had already taken hold. There was Mawhinney, also Presbyterian missionary, who undertook a similar trust in the adjoining native State of Sunth. Each of them took up his abode among the people in a hut like their own; he restored order and cleanliness; he instilled some of his own courage; and then each within a month of the other was stricken with the disease from which he had saved others, and died the death of a Christian.

There was Thompson of the Church Missionary Society, who had sole charge of a large district of Bhils in the Native States of Northern Gujerat. He was worn out with his heavy burden, and he was seized with cholera when 35 miles away from the nearest European, sur-

rounded only by his faithful Bhils. They tried to carry him into head-quarters, but on the way he told them to stop under a tree and there he died. As a comrade wrote afterwards, "he loved his Bhils and they loved him; he has been true to them in his death and they to him."

Lastly, there was Jenkins, a Civil Engineer in the Public Works Department, who was in charge of works in the Panch Mahals. He was lying in his house with high fever upon him, when word was brought that a certain work would soon be stopped and the people dispersed if further alignment were not made. He got up and travelled to the place, and did what was needed, and then returned, with his illness, of course, much aggravated. In two days he too was dead.

I make no apology for mentioning these names, for the blood of such men is the seed —and the sap—of Empire.

DISCUSSION.

The CHAIRMAN said he thought it would be the opinion of all that they had listened to a paper of a somewhat unusual character even in the annals of the Society. They had not been given a learned treatise, though no one would have been better qualified to give it than the author, had he chosen, upon the origin and incidence of Indian famine; neither had they had a paper crammed with figures, statistics, and tabulated accounts, such as were apt to find their way into Blue-books and into Moral and Material Progress Reports. Neither, again, had they had anything in the nature of a political pamphlet; but an officer had stood up before them distinguished, as he (Lord Curzon) had said in his introductory remarks, for his sympathy with the peoples of India, a sympathy never better shown than in the great famine which he had described, and which he had assisted to administer with surpassing devotion and zeal. He had stripped off the mask from the mysterious figure of India, mysterious at all times, but never so inscrutable as in the hour of suffering, and had shown exactly and actually what famine meant in its effect upon the people, their families, their households, their cattle, and their lives, and what were its incidents and lessons. Anybody who knew the author or India at all well would be able to certify to the truth of the picture he had drawn. Perhaps he himself might be allowed to give his testimony in its favour, on account of the experience he had necessarily acquired in administering the famine to which the author had referred. Sir Frederic had been one of his most prominent officers in that great undertaking; and as he listened to the paper he could not help recalling many incidents in the course of that terrible visitation, some of them witnessed in the company of the author. The paper, so full of eloquence and of pathos as it was, brought back to him the scene of the poor-houses, those places in which they had tried to collect the human drift-wood on the great ocean of destitution; the kitchens, where twice a day pottage was handed out to the groups of people, men in one part, mothers in another, and children in a third, all seated upon the ground; the hospitals, where the fever-stricken and emaciated patient were lying, with that gentle resignation they knew so well, side by side upon their humble beds; and the cattle-camps, where animal life was treated with as much care as though it was human. And perhaps, most of all, the paper brought back to him, as the photographs recalled, the spectacle of those great relief works, upon which the Government of India employed tens of thousands at a time. Sometimes it might be a road, where the gangs of workers were arranged, some according to their village, some according to their sex, and some according to their strength and size, engaged in breaking the stones that were to constitute the metalling of the road; sometimes it would be the embankment for some railway of the future; sometimes it would be a great tank, or reservoir, or lake construction, with a view to irrigation service in the time to come. There would be seen, as he had seen scores of times, thousands of men, women, and children, creeping with their loads up the great dyke, shooting the soil to the ground, hammering it down, and thus earning the small pittance which kept their bodies and souls together, and which was the sole means by which the Government of India saved them from the death that would otherwise have overtaken them, either in the villages or along the roads. All those experiences were sad enough, and it was unnecessary further to dwell upon them. But there were two popular misapprehensions connected with famine in India he would like to refer to. A good many people might imagine that the majority of the people engaged on the relief works were in a very emaciated condition, the sort of living skeletons that were sometimes seen in photographs appearing in the English illustrated newspapers at times of famine in India. He had looked with some interest that afternoon to see what would be the character and physique of the people who were depicted on the slides shown by the author, and he was interested to observe how entirely they bore out his own recollection, which was that, on the whole, the people seen on relief works were in an astonishingly good condition. And they were so because they had been taken hold of by the Government in time; and it was the Government's object, by the work and the pay it gave them, to keep them in good condition, as the only means of saving them from death. It was not the people on the relief works but the skulkers who could not be tempted out of their huts and hovels in the villages, the poor aimless wretches who drifted in hundreds and thousands from the Native States across the border into British territory and then perhaps back

again, and the thousands of people who were either too timid to solicit or too proud to accept assistance, that were the sufferers. They were the people whom Government was always trying to draw into its fold, and who, if it failed to do so, collapsed and died. The second popular error was the belief that the mortality that occurred in famine was in the main due to starvation, *i.e.*, to lack of food. Many as were the harsh and unjust charges that were brought against the British Government in India, there was none more cruel or ungenerous than the statement that millions of persons perished of starvation in an Indian famine. In the first place it should be remembered that what was called famine, was commonly only scarcity, in varying degrees of intensity. It was not the complete absence of food supplies or the death of persons resulting therefrom that was the chief difficulty, so much as it was the administrative problem of dealing with large masses of people, whose vitality was impaired. Secondly it was to fever, cholera, diarrhœa, and dysentery, all the diseases in fact that preceded or followed upon famine, that the mortality was principally due. If there was one thing more true than another in the paper, it was the remark that the Indian had not a reserve of physical or, he might add, moral resistance. His vitality was at all times at rather a low ebb, and when a great emergency came, particularly when that emergency was attended by illness and disease, he was apt to gutter out and die. In every famine there was, of course, considerable mortality, but in each visitation it grew less, because of the greater experience the Government had behind them, the more highly organised staff collected for the purpose, the programmes laid down for officers to carry out, and, perhaps, also because of the greater intelligence and understanding of the people themselves. It would be easy to go back to the native period of rule, before England took over the government of the country, and to show from the writings of native historians how different were the conditions in those days. It had been his duty to study many of those documents, and what the author of the paper had said was undoubtedly true—famine in those days meant a loss of life so terrible that often it amounted to the complete depopulation for an entire generation of districts as large as many States. It was characterised by complete and callous indifference on the part of the Governments of those times, by appalling sufferings on the part of the people, and, by horrible and revolting scenes. Those days had gone by never to return, and the change undoubtedly synchronised with the period at which the Government of India was effectually taken over by the British administration. If they looked at the long time that had elapsed since then, it would be found, he thought, that it might be roughly divided into two epochs. Firstly, there was a period of about 100 years, dating, say, from 1770, during which no scientific effort was made by the Government of India to cope with famine, not because it lacked the sympathy, but because it had not the knowledge and the machinery, and because at that time expenditure upon famine was regarded as the legitimate field of private charity rather than as imposing any call upon the funds of the State. That condition of affairs went on for a century and then some 40 years ago, dating with the Orissa famine of 1866, the revulsion came. From that time forward, the State commenced seriously to admit its obligations in respect of famine. With each successive famine the scope of that admission was increased, until it fell to his lot, in the famine of 1899-1900, to make the statement on behalf of Government that no single rupee would be spared by which they could hope to mitigate dire suffering or to save human life. Another cause and evidence of their advance was the fact that after each famine as it now took place, a commission of experts was appointed, who visited the localities affected, took evidence from all classes, official and unofficial, analysed the incidence and symptoms of famine, and then recorded their experience and judgment in a series of recommendations which at once fell under the attention of Government, and were probably made the basis of some pronouncement for future action. Hence it was true to say, as the author had said, that there had gradually been evolved in India a science of famine relief, a science sufficiently elastic to be capable of adjustment to the circumstances or the requirements of different times and localities, but at the same time sufficiently precise to be embodied in great codes of famine procedure drawn up for each province in India, which while suited to the circumstances of the district, were yet based upon broad principles of general adaptation laid down by the Government of India and applicable to the whole country. He had spoken of the fulness of the Government's acceptance of the obligation of relief; and he could not give a better idea of what that involved and the scale upon which it had been done than by pointing out that at one period, in July, 1900, there was a spectacle in India such as had never before been seen in any civilised country and which he hoped would never again be seen, namely, no fewer than six million persons in receipt of relief from the Government. Again, the Government stinted no money, as was shown by the fact that in that famine the total expenditure amounted to nearly ten millions sterling. As soon as the first indications of famine threatened, the Administration settled down to its work, prepared plans, and, when the visitation fell, carried through its operations from start to finish with just as much prevision, anxiety, and study, as a great commander might do who was laying down the lines of some momentous military campaign. That they would ever be able altogether to prevent famines in India, the climate and the population being what they were, was, he thought, at any rate within any time they could measure, extremely unlikely; that they would seriously reduce the frequency of famines he hoped

was probable; that they were markedly mitigating, that they had already markedly mitigated, the severity of their incidence might be regarded as absolutely certain. There were certain observations in the concluding part of the paper that he wished to associate himself with before sitting down. If administration in high places brought one, as he thought it sometimes did, in contact with the seamy side of human nature, a great ordeal like an Indian famine also showed one the reverse side of the picture. It showed one the nobility of which human nature was capable; its capacity for self-sacrifice, and its sense and power of duty. As he looked back on the experience of that time, he did not know whether more to admire the patient and uncomplaining resignation of the native peoples, the sufferers themselves, or the heroism of the officers, both English and native, civil and military, to whom the charge of all those suffering thousands was committed; or the devotion of the missionaries, English, American, Canadian, European, of every nationality, women as well as men. They literally stood for months between the living and the dead, and they set a noble example of the creed of their Master. Many of those persons rested in forgotten graves, but he hoped it was not presumptuous to cherish the belief that their names were written in the Book of Life. Let those who wanted to see what the British Government was capable of doing in India go there, sad as the experience might be, not in prosperous times, but when the country was in the throes of a great famine, and they would see what no Government in the world had ever attempted to undertake in the past, what no Government in the world, except our own, was capable of undertaking now, and what he firmly believed that no Government, European or Indian, by which we could conceivably be supplanted or succeeded, would dream of undertaking in the future.

Mr. Henry Staveley Lawrence, I C.S. (Director of Agriculture, Bombay), remarked that he was not privileged to take an active part in the noble campaign against famine of which the author had given so powerful and touching an account, but during the period in question he was employed at the head-quarters of the Bombay Government, and was in a position to observe very closely the progress of events. It was not necessary for him to add any details to the vivid pictures which had been drawn by the Chairman and the author, but he would base his remarks on two points only. In regard to the loss of cattle in the province of Gujerat, he might add the gratifying news that that province had, to a very great extent, recovered its losses. Last March, at a cattle show in Ahmedabad, the villagers assured him that, though good bulls were scarce for breeding, the six years which had passed had enabled them to restock their herds, and the cattle farm which Lord Northcote and the author had established in 1899 was being utilised for the gradual supply of that want. That farm was now in a flourishing condition, having been taken over by the Government and established as a permanent institution, and the want of good bulls was being slowly supplied from that institution. The author had referred to the duty of Government to invest its surplus revenues in irrigation, railways and agricultural improvements, and he should like to offer a few remarks on the first and third of those matters. Irrigation and railways were already fully recognised in the famine programme, but there was still some doubt about the matter of agricultural improvements, especially in connection with irrigation. It was known that a large extension of irrigational canals was taking place in India. In 1901 Lord Curzon appointed a Commission, whose proposals when carried out would increase by one-third the area now irrigated by canals, from 21,000,000 acres to 28,000,000. Those projects would be spread over some twenty years, and were estimated to cost £30 000,000 sterling. Of that programme the share of the Bombay Presidency proper amounted to 1,000,000 acres, and an expenditure of £4,000,000 sterling. It was difficult to appreciate the significance of those figures, but their importance to the Deccan, which was notoriously of all tracts in India the most liable to famine, would be clearer when he added that the area therein irrigated would be increased from 100,000 acres to 1,000,000 acres, ten-fold. But the point which he wished to lay stress upon was, that the task was not completed when the engineers had built the great lake reservoirs in the Western Hills, and conducted the canals to the arid plains of the East. While millions were being spent on those works, there was a danger of that expenditure failing of its full fruition for the want of a few thousands more There was a school of thought which, contended that Western science could teach little or nothing to the Indian agriculturist. It was true that the native cultivator was wonderfully skilful in struggling against the forces of nature, and in wresting a crop from the reluctant soil in spite of droughts and floods which threatened to overwhelm him with disaster. Nevertheless, in his opinion those gentlemen were mistaken; their ideas were based on the agricultural failures of 30 and 40 years ago, and they took no account of the modern development of scientific agriculture throughout the world. But in any case the question of irrigational agriculture was wholly different. The traditional lore of the Indian agriculturist was of no service to him when water was poured upon his fields in abundance such as he never dreamed of before, and he naturally made most serious mistakes in its application. That was the experience not only of India but in similar circumstances of Egypt, where Lord Cromer, with characteristic promptitude, had taken steps to instruct the fellaheen in proper methods of irrigation. Everywhere the cultivator was tempted to flood his fields excessively, in ignorance of the misfortunes which he was preparing for himself. Where the drainage was deficient his land became waterlogged, where the soil was impregnated with

alkali noxious salts would rise to the surface, and in all cases his plants ran to leaf and wood, and the fibre of his cotton or the grain of his cereals immediately deteriorated. Further, the man whose experience was limited to dry-crop fields of pulse and millet had no knowledge of the cultivation of the more valuable crops of long-staple cotton, sugarcane, and spices which were now for the first time within his reach. The Irrigation Commission recommended that agricultural experiment and demonstration should work hand in hand with the extension of irrigation; the expenditure required was comparatively trifling, and it was to be hoped that the spirit of retrenchment at present prevailing in affairs of State might not prescribe an unwise economy in that branch of the administration. As Director of Agriculture in the Bombay Presidency for the last five years, he had been able to see the difficulties of the people in dealing with circumstances of which they had had no previous experience, and he was convinced that the solution of the complex problems of irrigational agriculture required the assistance of the Department of Agriculture. That department was practically created by Lord Curzon shortly before his departure from India; and, if it continued to receive encouragement and support, it should secure the success of the irrigational policy, and be a powerful factor in safeguarding large tracts of country from the horrors of famine in the future.

The Rev. ARTHUR OUTRAM (late of C.M.S., Rajputana) said the author began his paper by saying that he was speaking as one who had come through the thick of the fight and who was an official. He (the speaker) presumed he had been asked to speak as one who also had gone through the thick of the fight, but was not an official. The author, in his valuable and interesting paper, had dealt largely with famine in districts in the plains, within reach of railways and in British territory; but to see the practical side of famine in India taken as a whole one had to look also at lessons learnt in those other districts, *i.e.*, in hilly tracts far from a railhead and (a subject which had to be delicately handled) in Native States. After the famines in these last-named districts, three practical lessons, among many others, seemed to suggest themselves, namely—(1) How to obtain a maximum of efficiency with a minimum of cost of administration. Could they not, with advantage, utilise to a far greater extent than was done, the ready-made relieving officers who existed in so many hilly tracts, where each village was on the old Scottish clan system, with headmen having unofficial perhaps, but nevertheless very real, authority? In those mountainous areas, five to ten days from the railhead, owing to the insecurity of the country at such a time and through other causes, *bunnias* could hardly be got to trade, and, therefore, all relief had to be paid in grain. In the 1899-1900 famine before starting a relief centre in the district in which he worked, the villagers were called together and, through their headmen, pledged that they would be responsible with an armed guard for all safety of grain, under certain penalties as to withholding seed grain and cattle, the able-bodied from the guaranteeing villages having certain privileges in grinding and cooking. Efficient checks were found easier to impose than at first sight might be imagined. The advantage of that system was that, beyond the actual cost of grain, no money went outside the famine district in the shape of overseers' salaries (remitted to their homes in non-famine areas), the villagers did not lose their self-respect, and the total cost of administration over the whole of his district amounted to only a fraction over 1 per cent. Then (2) more latitude in spending money. In those districts remote from the railways and when everything depended on animal transport, 20,000 rupees spent at once on grain, buying up forage and using the local animals to bring in that grain for storing while the wells still had water, was of far greater value than a lakh of rupees spent three or four months later when outside transport had to be pushed in. (3) As to the size of relief camps. From the author's paper one gathered that in the plains and railway areas large camps had advantages. In hilly and non-railway districts the selection of camps was circumscribed by the well supplies, which were in the valleys. One learned by mistakes, and perhaps those were most apparent to those who continued to live on in the districts after famine had ceased. At first sight large camps appeared to be better, cheaper, and easier to arrange for, but the after effects in hilly tracts might be far from pleasant. Apart from the insanitary condition of the ground inseparable from a famine camp, with its attendant epidemics, a large camp required such quantities of wood for cooking the food, making fires for warmth, running up temporary shelters for the destitute, and burning infected corpses during epidemics, that the originally fertile valley was afterwards only partially inhabitable; and, through the wholesale demolition of trees, the soil on the hillsides being washed away, hot and barren rock remained. Smaller camps, besides being more sanitary, not only seemed more adapted for districts dependent upon their own wood supplies, but, a greater number of camps being available, were more accessible to remote villages, and shy villagers would come more readily because nearer home. The cost of a greater number of smaller camps was certainly a little more than of larger ones, but if the policy of utilising the local headmen were more adopted, as he had suggested, the money would still all be spent within the famine area as famine relief.

Sir JAMES BOURDILLON, K.C.S.I. (late Lieut.-Governor of Bengal), said that as it had been his fortune, whether good or evil he could hardly say, to have been a great deal associated with famine work during his service in India, he would venture to make one or two remarks. Sir F. Lely had said a good deal about the welding power of adversity and suffer-

ing, and the Chairman had corroborated and expanded that remark by pointing out the way that scarcity and famine had developed the qualities, both of the relievers and the relieved. The author had mentioned the names of only a few of the heroes of his own presidency, and it would be impossible to give a complete and worthy list of all those who deserved the praises which had been uttered by Lord Curzon and Sir F. Lely. He himself could recall many with whom he had been brought in contact. They were men of all classes. There were missionaries and forest officers, especially the latter, and their utility in dealing with shy hill tribes, an art which could not be acquired by men of any other department, was beyond praise. He could recall doctors who had distinguished themselves by great devotion, and also men of the Public Works Department, civilians, police officers, and officers of the army, who, when others had fled, managed all departments of their charges by themselves. He could most cordially and thoroughly endorse what had been said about the famine bringing out the characters of those engaged. He would like to mention one instance which came under his own experience when he was Commissioner of Patna during the famine of 1896-7. He had at that time under his orders about 60 or 70 non-commissioned officers of British regiments. He confessed that when the proposal was made to him that he should put these men in charge of relief works he regarded the experiment with considerable suspicion. The British soldier was an unintelligible and a fearsome person to most natives in India, and, as a rule, had very little knowledge or very little sympathy with the natives: he knew little of their language, and still less of their customs and habits. However, the circumstances were such that he (Sir J. Bourdillon) was obliged to accept their aid; and although his apprehensions were grave and deep at first, he was glad to say that, by the end of the famine, he was able to send those men back to their regiments with the report that in not one single case had they failed to give entire satisfaction. They had adapted themselves in the most remarkable way to the surroundings in which they found themselves; they had proved themselves to be humane, patient, sympathetic, and in a very short time they won the complete confidence of the people among whom they worked. Neither of the speakers had said much upon one incidental point, namely, the effect on the people themselves, though they had spoken of the effect on those who relieved them. It had been said, by some who knew very little of the people of India, that they were ungrateful. That was emphatically not the case, and he was sure that everybody who had served in India would bear him out in that remark. It was one of his pleasantest recollections when touring round his division as Divisional Commissioner, when the famine was over and things were resuming their normal course, to remember the deep and wide-spread spirit of gratitude to the *Sirkar* which pervaded all classes and races in that Division. He would like to say a word with regard to the author himself. He (the speaker) was one of the Famine Commission of 1901, which, under the orders of His Excellency Lord Curzon, visited those parts of India which had suffered most in the famine of 1899-1900. The author's difficulties, it was an open secret, were enhanced by a circumstance from which other administrators of famines were generally free. Sir F. Lely for a long time was as a voice crying in the wilderness. At that time there happened to be no one at the headquarters of the Bombay Government who was intimately acquainted with the state of affairs in Gujerat. On the other hand, the author knew everything that could be known about Gujerat; he had served there many years, and he was well known for his devotion to the province and its people. He early recognised the gravity of the situation, and early proclaimed the necessity for instant, full and complete relief; but it was long before he could persuade the Government of Bombay to attend to his cries; therefore, whatever mistakes were made, were made not by him but in spite of his advice. The Government of India recognised that fact, and he was betraying no official secret when he said that it was the pressure brought to bear upon the Government of Bombay by the Supreme Government in conjunction with the perseverance of Sir F. Lely, that finally brought about that great measure of administrative relief which was given in that Presidency. In conclusion, he desired to refer to the fact that not a word had been said about Lady Lely. He was in Ahmedabad with the Famine Commission the year after the famine was over, and he there learned how much the author owed to the support and the encouragement of his wife. Lady Lely threw herself into the work of relief with as much enthusiasm as her husband, and he remembered hearing in particular how her devotion to the orphanages and to the cattle camps was an example to the wives of all the officials throughout the province. As an old famine officer he wished to say how true and graphic had been the word pictures, as well as the sun pictures, which the author had laid before his hearers.

The CHAIRMAN, in proposing a hearty vote of thanks to the author for his paper, remarked that what Sir James Bourdillon had just said recalled one incident to his mind. Sir James had referred to the difficulties that the author encountered in the early part of the famine of 1900 in obtaining the support of the local Government. That brought to his recollection one of the pleasantest incidents of his famine recollections, namely, a sweltering summer's afternoon when he, as Viceroy, was acting as arbitrator between the Bombay Government and the author. They sat for hours round a table discussing all the knotty problems, and it was his duty, after listening to both interests and acting with as much impartiality as he could command, to give his verdict, which he did in favour of the author. Those were

his sentiments then, and they were his sentiments at the present time.

The vote of thanks was carried unanimously, and

Sir FREDERICK LELY acknowledged the compliment.

Sir STEUART COLVIN BAYLEY, in the name of the Council and the whole audience, expressed their great gratitude to Lord Curzon for his goodness in taking the chair. It was not the first or the second time he had so honoured the Society; but they were especially grateful that, at a time when Lord Curzon was not taking part in public affairs, and was in a retirement which they all regarded with sympathetic feelings, he should have been present to show his devotion to the work of famine relief in India, and his regard and sympathetic recollections of the officers who served under him.

The meeting then terminated.

Dr. SEID ABDUL MAJID writes, as an Indian, to express his heartfelt thanks to Sir F. Lely for the noble work accomplished by him in alleviating the misery of the famine-stricken people of Gujerat, and his gratitude for the sympathetic speeches delivered by Lord Curzon and others. Dr. Majid suggests further that irrigation should be extended "to those parts of India which have more frequently been a prey to famine, and thus render the people independent of the monsoons." He also urges that modern implements of agriculture should be introduced as largely as possible. Lord Curzon, says Dr. Majid, never did a greater thing than the founding of the Agricultural College at Poosa (Behar). The writer adds:—"With respect to Sir F. Lely's difficulty in relieving those Indians who were too shy or too proud to accept relief, I am of opinion that if the task of distributing funds were entrusted to small committees composed of responsible landowners in districts, towns, and villages, this obstacle would be overcome."

Sir WILLIAM WEDDERBURN, Bart., writes:—In Sir F. Lely's paper yesterday, on the practical side of Indian famines, I was surprised that no reference was made to the great central fact, that the famines of 1897 to 1900 were not famines of food, but of poverty. To quote the words of the Famine Commissioners, "there was never in these years a dearth of food in any famine stricken tract." The cause of famine mortality was, therefore, not the absence of food, but the destitution of the masses, who had neither the coin nor the credit sufficient to buy in the bazaars the daily pennyworth of grain sufficient to keep them from death by hunger. This being the cause of famine mortality, the other practical question is, how may this cause be removed? Famine relief is all very well, but at best it is only mitigation of the calamity; and if prevention is better than cure, much better is it than mitigation. How then may famine mortality practically be prevented? The answer is a simple one, by providing that the villagers should have such a reserve of food, or money, or credit, as will enable them to tide over the failure of one harvest. This may not sound a heroic remedy, but it is a practical one; and in order to carry it out, we need that economic village enquiry, after the method of Messrs. Booth and Rowntree, which was asked for by the Indian Famine Union. The village community is the unit of India, and when we have ascertained how to make one village moderately prosperous, we get the clue by which we may make safe from death by hunger the half million villages which contain the rural masses of India.

Mr. A. ROGERS, who was prevented from taking part in the discussion owing to want of time, desired to call attention to a measure which he hopes may tend to the prevention of famine among a large section of the community, especially the Bhils and wild tribes in the Bombay Presidency and Western India. He writes:—

"It has been amply proved that the late famines with which India has been afflicted did not arise from the actual absence of food, for grain was abundant, having been carried by the railways which happily now perform that necessary task, conveying it from parts of the country where crops have been raised to others where the monsoon has failed, but from the absence of employment through which the population could earn wages with which to buy the food that was to be had in almost every village throughout the country.

"Whilst the famine of 1899-1900 was at its height I happened to be, in a private capacity, in the southern part of the Panch Mahals, where the crops had entirely failed through want of rain. I consequently saw it at its worst at Jambághora, the official residence of a Mahalkurry, where a line of road was under construction to provide labour for those who were in want. By some mistake, while provision had thus been made for the able-bodied among the people, a poor-house, at which the feeble, the women and the children would be fed, had not been established, and hundreds were literally starving. This mistake was rectified in a short time when I represented the state of matters to Lord Sandhurst, the Governor of Bombay. All this pointed to the necessity for means of employment for the people by which they could earn wages wherewith to buy food, which the local trader had collected in abundance, but which the people could not buy.

"I have now to point out that there is a species of employment congenial to the Bhils and other wild tribes of that neighbourhood and many jungly parts of the Presidency, which has been entirely neglected. I discovered that the *Antheræa mylitta*, the worm

that produces Tassar silk, for which there is an unlimited demand in England, are indigenous to the country, the cultivation of which would have provided ample employment for the people and prevented the arrival of famine at all. I propose that the Government of Bombay should nominate a Commission, to consist of the Revenue Commissioners, Collectors, Trust Officers, and others, whose first duty should be to collect as large a quantity as possible of the cocoons, of which I have specimens, when procurable, of such as had not been eaten through by the chrysalis which had not turned into a moth, for transmission to England for examination at Bradford and other places where Tassar silk is utilised. This should be followed by the encouragement of the culture of the worm itself by Bhils and other wild tribes, and the establishment of village reeling factories in various localities by measures which could not be specified here in detail. Such measures would start a new industry, such as all interested in the subject are agreed in considering necessary for the prevention of famine, and not meeting it after it has arrived.

"Why such an industry has not long ago been established by the Bombay Government I cannot understand, and I hope no further delay may be allowed to take place in doing so.

"P.S.—There are silk factories in several places in Bombay, where experts in reeling could be procured to instruct the Bhils."

TWELFTH ORDINARY MEETING.

Wednesday, February 27th, 1907; Sir JOHN CAMERON LAMB, C.B., C.M.G., Member of the Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Charlesworth, Charles Dixon, 72, Egerton-road, Withington, Manchester.

Euba, Rev. W. B., Wesleyan High School, Marina, Lagos, West Africa.

Firminger, Rev. Walter K., B.D., M.A., Kidderpore Vicarage, Calcutta, India.

Robertson, Vincent Leopold, Rolfontein, P O. Amersfoort, Transvaal, South Africa.

Tebb, William Scott, M.D., Sandfield, Putney Heath-lane, S.W.

Wallace, Captain William Thomas Ewart, Entebbe, Uganda Protectorate, British East Africa.

The following candidates were balloted for and duly elected members of the Society:—

Foster, Edward, Irwin, Montego Bay P.O., Jamaica, British West Indies.

Gröne, H. Dawson, Inspectorate-General of Customs, Peking, China.

O'Brien, Lieut.-Colonel J., 4, Atherstone-terrace, Gloucester-road, S.W.

Scott, John Gray, Tramways Office, Hong Kong, China.

Sen, Baikunt Nath, Saidabad, Khagra P.O., Murshedabad District, India.

Treble, Mrs. Lillian Massey, Toronto, Canada.

The CHAIRMAN, in introducing the lecturer, said that Mr. Morton had for long been the Examiner in Typewriting to the Society, and the Council highly appreciated the work he had done in that capacity. He was sure Mr. Morton would present a useful and interesting paper.

The paper read was—

MODERN TYPEWRITERS AND ACCESSORIES.

By ARTHUR E. MORTON.

It is universally conceded that writing machines, by eliminating the delicate muscular labour that so greatly reduces the speed of pen work, have effected one of the most notable of the quiet revolutions in the literary and commercial world of recent times. They have crowded out opposition and lived down all reproaches, and clearly proved their claim to be considered time and labour-saving instruments.

The title of my address "Modern Typewriters and Accessories" indicates that I am not expected to present you, in historical sequence, an account of what has transpired in the typewriter world since the introduction of the first marketable machine in 1875; I would, however, state that no sooner had the typewriter acquired a commercial value, than the fire of inventive talent was awakened in Europe and America, and typewriter after typewriter appeared on the market—a few came to stay, but the many disappeared, either during or shortly after the chrysalis or experimental stage had been passed. Inventors and investors have learned, to their sorrow, that hasty innovations and untried experiments spell "failure" in the typewriter field, and only patient and careful study, backed by experience, tireless effort, and abundant resource, have a chance of success.

In the spring of 1888 a valuable paper entitled "Typewriters and Typewriting" was read before this Society by Mr. John Harrison. A perusal of this paper shows that the number of machines then seeking the patronage of the

British public totalled six, viz., "The Caligraph," "The Columbia," "The Hall," "The Hammond," "The Remington," and "The World." Of these only the Remington and the Hammond are to-day on the active list.

In the spring of 1894 Mr. Henry G. Jenkins delivered two Cantor lectures before this Society on "Typewriting Machines." The first traced the evolution of the machine from 1714 to 1875, and the second dealt with developments from 1875 to 1894. The second address makes reference to sixteen machines as being then on the market, viz., "The Bar-Lock," "The Caligraph," "The Columbia," "The Crandall," "The Densmore," "The English," "The Fitch," "The Hall," "The Hammond," "The Maskelyne," "The Munson (now Chicago)," "The Remington," "The Smith Premier," "The Waverley." "The Williams," and "The Yost."

Thus, in the six years which elapsed between the delivery of these lectures, an increase of ten different machines has to be recorded, and of the sixteen machines referred to by Mr. Jenkins only eight survive, viz., the Bar-Lock, Densmore, Hammond, Chicago, Remington, Smith Premier, Williams, and Yost.

Since 1894 an addition of thirty-two machines can be ecorded, making in all forty-eight different instruments. Of these twenty remain on the market. I would point out that scores of machines have appeared on the American market, but my list takes cognisance only of those offered commercially on the British market.

Naturally many changes of the details of construction, tending toward a greater ease and convenience of operation, strength, and durability have been embodied in machines, especially those first introduced and referred to in the two lectures before-mentioned.

"Modern Typewriters" may be defined as billing, tabulating, book recording, card indexing, and document writing machines. They are speedier and produce finer and more varied work than their predecessors.

The manner in which the typewriter performs its work is of the simplest. For the benefit of those present unfamiliar with the typewriter it may be considered as composed of three general parts, as follows:—

The Keyboard, by which the operation of the machine is directed.

The Type Mechanism, by which the desired letters are, one after the other, in any desired sequence, imprinted upon the paper.

The Carriage, which holds the paper in proper position for writing, and which, by its regular movements, provides for the spacing of letters and lines.

A very brief examination of the machine will serve to make the novice familiar with these general parts and the absolute simplicity and directness of their relation to one another.

For illustration and explanation I have selected the "Remington"—which may be considered the pioneer of writing machines. Some of the favour this machine has met with may, no doubt, be attributed to the prestige of priority, but this alone would not account for its widely extended use. The fact that the manufacturers are always ready to introduce alterations which tend to improve, will account in a great measure for its popularity.

The "Remington No. 2" was used by Mr. Harrison to illustrate his address in the spring of 1888. In the autumn of that same year the No. 5 model was introduced. It was similar in the main lines of its construction, but its working capacity was increased by the addition of four more keys equivalent to eight extra characters. It was for many years the favourite writing machine in this country, for which it was specially designed.

In appearance it is square, and strikes a novice as being somewhat complicated. It is only the multiplicity of parts, however, which creates this impression. The machine is not complex, the same parts being repeated over and over again. The action is simplicity itself.

The machine is quite open on every side, so that its entire construction can easily be seen. There is a japanned iron frame enclosing and holding the working parts, consisting of a base, four upright posts, and a top plate. In front is a series of keys arranged in four banks like the keys of an organ, each key representing the two characters, termed "upper" and "lower" case letters. These are connected with long light wooden levers, which, being depressed, communicate motion by means of a rod fastened to the lever to a type bar. At the end of each type bar is fixed the hard metal type representing the two characters. The type bars are arranged in a circle, therefore the point of percussion of the type on the paper is at a common centre. The inking is done by a ribbon, which travels automatically across the machine, winding and re-winding on and from spools.

The paper is inserted between two rollers; one of rubber, called the "paper cylinder,"

and the other of wood, called the "feed roll." The rollers are held together by two elastic india-rubber bands. As one revolves so does the other. The portion which holds these rollers is designated the "carriage." By a clever yet simple piece of mechanism this carriage is caused to travel, simultaneously with the return of the type or spacing bar, from right to left, the width of a letter at each movement, across the machine. The carriage works on a sliding frame, and this sliding mechanism is controlled by two keys which do not impress letters on the paper. These correspond to the silent but important "combination stops" of an organ. They change the character of the printing keys, causing them to print capitals or small letters, numerals or other marks at will. Depress the key marked "upper case" and all the keys will print capitals; remove the finger and they all print small letters again. Moreover, the machine can be arranged to print capitals continuously by the mere raising of a lever, and quite independently of the "upper case" shift key.

To obtain an impression the required key is struck lightly, and the type bar causes the type to strike against the ribbon; thus leaving an imprint upon the paper held round the cylinder; the carriage moves automatically the width of a letter, and the operation is repeated until a word is completed. Then the "spacing bar" at the front of the machine is depressed at any point, thereby securing the requisite space between the words.

When the end of a line is reached, warning is given by the ringing of a bell, and then, by pulling out the lever at the right hand side of the carriage and gently pressing to the right, the paper carriage is advanced into position to receive the next line. The distance between the lines and the width of the writing can be regulated. The paper-carriage being hinged at the back allows of its being raised from the front by the hand so that the line just written can be inspected.

The motive power is imparted by an adjustable coiled spring, a thin leather strap being fastened to it and the carriage, and the uniform space is governed by two clutches working on a rack. This rack is fixed on a rocking shaft, and derives a swinging motion from a universal bar fixed beneath the light wooden key levers.

In the machine under review—Remington No. 5—a small lever attached to the left of the carriage places its movement under the control of the operator. Two scales are fixed on the machine, and these, in conjunction with a pointer, permit of headlines being centred, corrections made, &c.

It will be opportune at this stage to turn attention to machines in general. "Modern Typewriters" may be classed under two heads, viz.: Type-bar machines, and Type-wheel machines. The "Type-bar" machines have the type on the free end of bars arranged in a circle or a semi-circle, the point of percussion of the type on the paper being at a common centre. This class of machine embrace by far the largest number of modern typewriters. To this class belong the Bar-Lock, Densmore, Empire, Fay-Sholes, Fisher, Ideal, Monarch, Oliver, Pittsburg-Visible, Remington, Salter, Smith Premier, Underwood, Williams, Yost.

The "Type-wheel" machines have the type arranged on the periphery of an oscillating shuttle or wheel. To this class belong the Blickensderfer, Hammond, Munson (now "Chicago").

The inking of the machines comprising the two classes is accomplished generally by a ribbon, but in some machines a pad is employed.

In some machines a special key and its accompanying mechanism is provided for each character or sign used — such are termed "complete" keyboard machines. In others, each key is made to represent the letters or signs—such are designated "single-shift" machines. Others, again, have two shift-keys, and each key represents not only a lower case (small) and an upper case (capital) letter, but a figure or other sign as well—such are known as "double-shift" machines.

The time at my disposal this evening will not allow of my describing in extended detail each of the twenty typewriters seeking the public patronage. I will, to the best of my ability, put you in possession of the chief points of each as briefly and succinctly as possible. With this object I have arranged the two classes of modern typewriters into three groups, viz.:—

"Blind" writers, in which the writing remains hidden until exposed by manipulative effort of the operator. "Semi-visible" writers, which show only the last lines, or only expose the centre of the paper, hiding the writing at both ends of the line. "Visible" writers, which expose a character directly in front of the operator the instant it is imprinted, and which subsequently does not pass out of

sight, by feeding behind a scale or bar, or other obstruction. This classification and grouping is for convenience only, and is in no way intended to denote superiority.

the carriage, and can be turned forward or backward at will. The ribbon movement is improved and works entirely automatically, reversing and giving a lateral movement. The marginal stops also are improved, and simple means provided for writing outside the margins whenever desired. There is a keyboard lock, locking the types at the end of the line, and thus preventing one letter being printed over another. A new variable line spacer is embodied which makes it easy to write at any point on the paper, and prolongs the life of the platen for the reason that the type no longer strike in unchanging grooves. An adjustable side guide for arranging the paper to any desired marginal indentation is a recent addition. A new two-colour ribbon lever bearing a disc which signals the colour which the machine is adjusted to write is another recent addition.

TYPE-BAR MACHINES.

THE REMINGTON.

I have previously stated that many changes of the details of construction, tending toward strength, durability and a greater ease and convenience of operation has been introduced into the machines which have survived the severe test of time. This is especially the case with the Remington. I have only time to refer to the most important of these valuable improvements. They are:— An entirely new form of escapement, giving increased speed and an easy touch. The carriage is stronger and lighter, and steadier in all respects. The annoying rubber bands which guided the paper round the platen have been discarded for a new form of paper guide which can be adjusted to any desired point. The paper feed has been so arranged as to render it possible to write on wide or narrow paper, and this can be fed into the machine by a simple movement of the hand without lifting

The No. 8 group of Remingtons permit of the interchange of smaller size carriages being readily substituted for the regular size carriage.

Both the No. 7 and No. 8 group of machines

can be fitted with a decimal tabulator, double circular line scale, &c., for billing or tabulating purposes.

Densmore.

The keyboard is the standard "single" shift, with the addition of a lock-key and a back-spacer key. Two uniform shift keys are provided, either of which will shift from small letters to capitals, or the reverse.

The back-spacer key for each depression causes the carriage to move backward one space, enabling the operator instantly to print a faint letter over again, to cover an error, also numbers can be added and the total written in from right to left by striking twice after writing the figure of each column.'

Each type-bar, in addition to a wide bearing, has a supplementary lever, which receives all the strain from its connecting rod, and is protected from wear by ball bearings, each side of the joint containing five hardened steel balls, secured by an ingenious hollow nut, absolutely avoiding lateral play.

The ribbon movement has both a longitudinal and lateral direction, is provided with an automatic reverse, and can be instantly thrown out of gear for duplicating purposes. The writing is brought into sight by tilting the platen forward, which platen is instantly removable.

The justifier is one of the original features of the latest model. It is a gauge with which the paper can be moved to the left any fraction of a full space. It is useful in contracting a word to fit a desired place, *e.g.*, *them* can be substituted for *him*.

A graduated marginal guide on the paper table is provided to insure uniform margins upon the pages.

Variable line-spacing is secured by giving an inward pressure on to the right hand thumb wheel—the machine continuing with the regular spacing from the exact point where the platen is stopped. Line locks, marginal stops, &c., are provided to cover such adjustments and conveniences as are known in practical typewriting. The ordinary carriage of the policy, brief, or draft models can be removed and any smaller size carriage substituted.

Fay-Sholes.

The essential features of this machine are two in number. It is a "single" shift machine, but the depression of the shift-key does not affect the carriage in any way, but shifts the whole of the type-basket, which is brought forward on ball-bearings. If it is desired to print all capitals the basket is shifted and automatically locked, and upon being released returns to its original position for small letters, and is also locked in this position. It is claimed that the result of this arrangement is that all the writing parts are kept in the proper relation to each other, thereby maintaining perfect alignment. The second feature is that five interchangeable carriages for billing, statement, pay-roll, inventory, insurance, or other special work, may be fitted to any Fay Sholes.

The ribbon is not automatic in the reverse movement—there is, however, a "reverse ribbon" signal provided in the form of a key-lever lock, thus attracting the attention of the operator. The act of reversing the ribbon exposes a fresh track or ribbon surface to the type. Each machine has a built-in tabulator for column writing or paragraphing. The machine is provided with the usual devices for writing on ruled lines, and for changing the depth and width of the line spacing, &c.

Smith Premier.

This machine is a very prominent member of this group. There are now on the market six models of the Smith Premier, although they resemble each other entirely in their mechanism, and differ only in the carriage arrangements, or the number of characters. The machine is particularly simple in construction, and claims, by means of a very long and strong adjustable bearing, to have secured a perfect and permanent alignment. The type-bars work on hardened steel bearings, $1\frac{5}{8}$ inches apart, and the type-bars are the shortest of any on a "complete" keyboard machine. But the original and exclusive feature of this machine is the rocking shaft, which replaces the usual wooden or metal key-lever. This consists of a circular rod, passing from the front to the rear of the machine—one rod for each key. Projecting from each shaft is a small bar, which is attached at the front end to the lower portion of the key stem. A similar projection is attached to the rod communicating with the type-bar, and the result is that on the depression of the key the rocking shaft is made to revolve slightly and so raise the free end of the type-bar to the printing point. The type-bar hangers are solidly rivetted to the type ring. It will be seen that matters are so arranged that the amount of force to imprint the characters is precisely the same in every case: a uniform, light, and elastic touch. A very noticeable

feature is its quietness in operation, due to the rigidity of its parts, and the fact that the ball-bearing principle is adopted wherever it can be used to advantage. It is also equipped with a circular brush, built into the machine, into which a handle can be immediately inserted, when, with a turn or two, the whole of the type can be cleaned.

Another point is that the platen is merely rocked forward to bring the work into sight. The platen can be removed immediately, carrying the work with it, and another platen substituted. The carriage is mounted on ball bearings running on hardened steel rails inside the carriage frame, which constitutes a practically frictionless bearing, while holding the carriage perfectly rigid against side motion.

The most striking recent development is the adoption of a three-colour ribbon device. A simple movement of the lever in front of the machine brings the required colour into place ready for use. A two-colour or single-colour ribbon may be employed, if desired. The ribbon can be instantly shifted from the printing point for duplicating purposes. The ribbon reverses automatically, and it is attached to the spools by clamps—one on each spool, dispensing entirely with pins and tapes.

The No. 9 model is fitted with four interchangeable carriages of various sizes, and it prints 96 characters; 84 are provided on the other models, excepting No. 2, this has 76.

The Yost.

The Yost possesses three distinguishing features. These are primarily—1. The ink pad. 2. The centre guide. 3. Great beauty of work.

The ink pad consists of a circular metal case, fixed round the top of the type-basket, against which the type rest. This pad is charged with moist ink, sufficient for continuous writing over a long period. This ink is imparted direct on to the paper by the act of printing.

The type-bar is a very peculiar and remarkably clever contrivance, not taking a direct sweep upwards as is generally the case, but is set loosely in its bearing. Any wear, therefore, can in no way affect the alignment, as the type-block strikes upward through a small hole in a guide plate. This hole is just large enough to allow the type to strike through without any play, and is so shaped as to conform to a bevel on the type-block, so that no friction can arise. The result is that, whether one thin sheet or a dozen thick sheets are in the machine at any time, the alignment is in no way affected. The touch is remarkable for its lightness, in view of the compound leverage adopted in the type-bar action.

The No. 10 standard model prints 85 characters, a separate key being provided for each character, yet the keyboard is conveniently condensed, being arranged in straight lines, vertically and horizontally. The carriage can be lifted bodily away from the machine, carrying with it the work that may be in process of execution, and can be replaced without the slightest danger of shifting the paper. To remove and replace the carriage is the work of a few seconds.

Very useful features are the facility with which type-blocks and buttons can be removed and others inserted for either temporary or permanent purposes, and the holes in the paper blade for ascertaining when the bottom of the paper is being approached. By pressing a spring the platen can be made to turn either backwards or forwards for typing on any desired position on the paper.

The large machines can be fitted with interchangeable carriages of smaller size. Any Yost can be fitted with a decimal and £ s. d. tabulator and invoice day book device, or a two-colour attachment.

The Bar-Lock.

This machine was placed on the market in 1888 and inaugurated a new era in typewriter construction—that of "visible writing" and a "complete universal keyboard"—ideas which have been largely followed by subsequent inventors. Many other ingenious and valuable devices, now generally adopted, originated in this well-known machine. In 1904 its manufacturers placed on the market a "single-shift" keyboard machine provided with 42 keys printing 84 characters; but machines are obtainable equipped with 45 keys printing 90 characters.

The type-bars are balanced upright in two half-circles on wide right-angle adjustable bearings, the front or lower half-circle containing the small or "lower case" letters, and the upper half-circle the capital or "upper case" letters, numerals, commercial signs, and a portion of the punctuation marks. The free end of the type-bars descend to print; thereby, every letter as written is in full sight of the operator.

The machine derives its name from a semicircle of phosphor bronze conical pins fitted in a plate at the printing point, so that every

type-bar, in descending to print, passes between two of the pins and is locked against side-shake or vibration, thus preventing the letters printing out of the straight line. As a further check upon the alignment, each type-bar is fitted with an adjustable truncated cone bearing, which can be tightened up if the bearing by long wear should become loose.

When the type-bar descends, the ribbon is moved so as to be over the line of writing, but directly the type-bar ascends, the ribbon moves back, thereby the writing is completely visible.

The machine is equipped with the following: Automatic ribbon reverse. Automatic right and left marginal devices. Keyboard locking and release key. Automatic paragraphing device. Interchangeable ribbon spools. Switch for throwing ribbon out of gear when stencilling. (At the side of machine on complete keyboard; below key-levers on shift-key machine.) Removable platen roll without taking the carriage off the machine or undoing any screws (useful in manifolding). Accountant attachment (accessory).

The Salter Typewriter.

The "Salter" typewriter is manufactured at West Bromwich, near Birmingham. The machine is the only typewriter made in Great Britain. A few chief points of excellence in the "Salter" are:—Perfect alignment, which is secured without the use of centre guides or complicated type-bars. Direct action from the finger key to the printing point. The type-bars are of specially designed girder section, stamped under enormous pressure from steel, they are, therefore, absolutely rigid. The keyboard contains 28 keys, which, with two shift-keys, gives a total number of 84 characters. The carriage escapement is constructed of steel, with very few parts. It is rapid, simple, and reliable.

The "Salter" is a semi-visible writer. The ribbon has an automatic reverse movement of simple but very ingenious design. By reason of the direct "downstroke" action of the type bars, and the sharp clear face of the steel type, the cutting of stencils is a good feature.

George Salter and Co., have been manufacturing typewriters for some twelve to fourteen years, and their present model proves that a first class instrument can be produced in Great Britain by British workmen.

Underwood.

This machine is built on the front up-stroke principle—each key lever on depression rocks forward a vertical connecting stud lever, the stud of which operates in the link of the type-bar, causing the free end of the latter to rise with a gradually accelerated movement to the printing point. Each key-lever is fitted with an independent adjustable tension, a feature which permits of varying degrees of touch without affecting the speed of the escapement action. This is useful in the "non-visual" system of manipulation in which the outside keys are operated by the little fingers, and these being weak need a lighter depression of the keys than the centre ones which are depressed with the strong index fingers; or, again, in increasing the amount of force required, say to prevent the punctuation marks piercing the paper or indenting the platen.

The alignment is secured by the type-bar swinging at its base through a slot at the bottom of the segment plate, and by a "V"-shape guide at the printing point—the type-bar while printing is thus held rigid at each end, although it is flexible while in motion. The type-bar is arrested by a projection on the segment, which prevents the type from puncturing the cylinder or perforating the paper should the force of the blow on the key be in excess of that required. The characteristic formation of the type-bar renders it impossible to batter the face of the type by striking one against the other.

Another feature is that each type-bar is quickly removable and another bearing different characters, may be substituted and this without affecting the alignment. The up-stroke principle ensures absolute visibleness of the text. The keyboard is a "single-shift," and arranged on the Universal style, with the shift-key in duplicate.

The inking is accomplished by a ribbon winding on and from two side spools, and carried through a frame across the printing point. A bi-chrome ribbon attachment can be fitted, by the use of which the ribbon can be adjusted for stencil purposes. A built-in stop-tabulator forms an integral part of the machine—a feature of this device is a leather brake acting on a rocking stop-rack at the back of the machine. All the usual conveniences for practical typewriting are provided.

The Monarch.

This machine embodies the front up-stroke principle of construction, retaining the well tried pivotal bearing. Uniformity of stroke is secured by a shifting or rolling ful-

crum, which gives an extremely light and elastic touch. The key-lever and type-bar mechanism is so balanced that it ensures a very rapid return—the bar will return to its resting point even without the assistance of springs. The writing is wholly visible. The keyboard is the standard "single-shift," the shift-key being in duplicate and conveniently placed. In addition there are two supplementary keys, one the shift-lock for capitals, and the other a tabulator key, a stop-tabulator forming an integral part of this machine.

The type-bar segment, which responds to the depression of the shift-key, has a vertical shift working on race ways in which are placed roller bearings—this allows of the introduction of a rigid carriage, which also runs on race ways and roller bearings. These race ways are adjustable for the purpose of taking up wear. The ribbon movement is from two side spools. The fabric is carried through a guide at the printing point. One colour or two-colour ribbons can be used, a switch enabling the change to be instantly effected from one colour to the other. The ribbon has three separate movements, end to end, automatic reverse, and a serrated or sinuous travel across its width, but when writing with a parti-colour ribbon the fabric is used straight along its length.

Other special features are a combined carriage feeding attachment and line indicator—this enables the typing to be executed from the extreme top and bottom edges of any size of card; there is also a plate which presents a flat surface for purposes of erasure.

I am informed that the latest development is a contrivance for automatically indicating when the bottom edge of the sheet is being approached. The Monarch is fitted with all necessary conveniences for line locking, margins, margin release, variable and fixed depths of line spacing, &c.

The Ideal.

The Ideal typewriter is manufactured at Dresden, Germany, and is really an ideal machine in more than name. It is a type-bar machine, each bar being made of steel formed in a "U" shape, giving lightness and rigidity. The alignment is secured in a three-fold manner, viz., by a directly-guiding lever, by a type-bearing guide at the base, and a type-lock at the printing point. The blow of each type-bar is positively controlled, any excess being received by a steel check, thereby reducing to a minimum the wear and tear of type, ribbon, and cylinder. As all the type-bars strike from one side, the alignment is not affected by increased thickness of paper being used when manifolding. The writing is absolutely visible. The ribbon movement is not wholly automatic, but the ribbon can be easily removed and replaced. The machine is fitted with a back-rack space operated by a key conveniently placed immediately above the left shift-key, also a variable line-spacing device. The bottom edge of the paper can be determined, the operator being able to see at a glance, at all times, the exact amount of paper available.

An accessory is a simple and efficient and decimal tabulator, which instantaneously places units under units, tens under tens, and hundreds under hundreds, or £ s. d. in their correct relation one to another with the same ease and rapidity as ordinary pen-writing.

Pittsburg Visible.

This machine is constructed on the front upstroke principle—the type-bar striking on the front of the platen, thereby securing absolute visibility of the text. Each type-bar moves in an individual guide and each type-block enters a central guide at the printing point.

The keyboard is a "single" shift, composed of 40 keys. A distinctive feature is that the entire type action—including both type and keys—are interchangeable. Different languages can be used on the same machine; the insertion of an entire type section in place of another can be instantly accomplished. The type is easily cleaned.

The ribbon winds on and from two side spools, passing through a guide at the printing point. The type strikes the ribbon between its centre and upper edge. Therefore, when the colour from the top edge is exhausted, by turning the opposite edge the unused half is brought into service. It lacks an automatic reversal action.

Another feature is that the carriage can be removed for cleaning and oiling purposes. Machines built with a wide carriage can be equipped with an additional carriage of smaller size on the same base. The machine weighs complete, with base board and metal cover, 20 lbs.

The Empire.

The Empire is a machine of original design. The movement is a straight direct thrust, effected by the simplest system of leverage. The depression of the key-lever, which works on a central fulcrum, puts in motion a pivoted

connecting bar, which in its turn drives forward the type-bar, the return being effected by a comb spring acting on the key-lever. The keyboard consists of 28 keys, each representing three types, making a total of 84 characters, which are brought into position severally for small letters, capitals, and figures, by means of two shift-keys.

Features:—Carriage at back. Platen roll interchangeable. Line lock. Compact and portable; weight, with travelling cover, about 24 lbs.

The Oliver.

The Oliver differs in mechanical principle from other machines. It has a wide "U" shaped steel type-bar, provided with a tool steel axle as broad as the bar is long, and brazed joints insuring the alignment without guides. The connection between the type-bar and the key-levers is direct and perpendicular. The type-bars strike down upon the platen in a line perpendicular to its plane, thus transmitting the maximum power with the minimum resistance, and further, maintaining the alignment with several sheets as with one. The type are of steel, and lie face upward—very convenient for cleaning. The keyboard is the "Universal"—the No. 3 model having 28 keys with a "double" shift, giving 84 characters, and the special model 32 keys, giving 96 characters.

The tension and depression of the keys are light and uniform. It might also be noted that the type blocks decrease in weight with the increase of length of type-bar—necessary to secure a uniform stroke The escapement mechanism is exceedingly simple and positive, and although very rapid is almost frictionless. The writing is semi-visible. The carriage is provided with three paper feed rolls, thus ensuring a perfect feed of the paper down to the bottom edge of the sheet. It runs on anti-friction travellers on guide rails, ensuring an easy and steady motion. It is equipped with all the necessary devices. The line space mechanism operates automatically as the carriage is returned from the left to right for a new line. The machine is compact and portable—weight about 20 lbs.

The Williams.

This machine exposes to view the last two or three lines written, and is, therefore, wrongly classed as a "Visible" writer.

The keyboard consists of 28 keys arranged in three banks according to the standard arrangement. Besides these there are two shift-keys which gives the machine a possibility of 84 characters. The 28 type-arms are each provided with three characters.

The faces of the type, when at rest, are on the surface of two ink pads, in two quadrants. Upon a key being depressed, the corresponding type-arm rises from the ink pad and strikes downward upon the platen, the carriage moving automatically with each stroke from right to left across the centre of the machine.

Alignment is maintained by a double system of guides, each type-arm having an individual guide, and all of the type-arms entering a common central guide at the printing point, which guide also answers for an indicator or pointer for purposes of correction, tabulation, &c.

The paper carriage is between the two quadrants, thus necessitating frames to hold the rolled up top and bottom portions of the paper. It travels on ball bearings on a single rail, a single motion of the hand returning the carriage and turning the paper forward for the next line.

The margin stops, line lock, and margin release are conveniently placed, and the line space gauge provides for four different depths of spacing between the lines. The platen roll is interchangeable. The ink pads can be readily removed for re-inking or for changing kind or colour of ink to another.

The manufacturers offer a No. 6 model equipped with 48 keys and a "single-shift"—in duplicate—fitted with an automatic lock.

The Fisher.

This machine is distinct from the ordinary typewriters in that, instead of the paper travelling across the machine, the machine travels across the paper, the paper laying in a flat or spread out condition. Having this feature, it is possible to write upon a series of sheets of varying heights and widths so as to write partial information on some sheets and whole information on others; thus, in writing an invoice, the sheet beneath it may be a copy for the warehouse, omitting prices, beneath that may be a copy for the factory, omitting the name of the customer and prices, but giving only the number of the order. The writing surface or platen being hinged at the rear, operates to allow of the introduction of a bound book. The book is placed upon a rising and falling table, the platen is brought down upon the open book, and the page to be written on turned over on to the platen. These

machines can be fitted for special purposes with an endless belt of carbon for use with folded forms, which forms are placed over and under the carbon, and after being written upon, are withdrawn from the machine without any handling of the carbon. The writing is in sight: it has a universal spacing mechanism, and the interior of the machine is fitted with an electric light for use where the ordinary lighting is deficient.

The Fisher is mostly used in the booking department for dealing with almost every operation of that department, including the writing of invoice and day-book, statement work, and minute recording work. It is also eminently adapted for tabulated work. It writes upon paper of any width—folded or single—and on the heaviest of cards. Writing on a flat surface, the manifolding capacity is very high, and stencil work can be executed without any creasing or cracking of the stencil, for the reason that the wax sheet lies flat.

This machine is now fitted with an adding attachment that adds any column of figures as written. It will add one column or any number of columns—limited only by the number of recording registers that can be placed on the machine at one time.

The paper can be fed into the machine from a roll or a series of rollers, the carbon being fed through the papers transversely from rolls of carbon on either side of the platen.

The Hammond.

This machine has its type all contained in one piece, and the paper is brought into contact with the type by a spring hammer that gives a uniform blow, irrespective of the energy with which the key is depressed. In the centre of the machine is secured a horizontal guide ring, called the "anvil," round which, under the action of the keys, slides back and forth a light curved plate of vulcanite, known as the "shuttle," containing 90 characters arranged in three rows, each covering an arc of about 120°. The ingenious mechanism by which the momentum of the shuttle is arrested and the impression made is as follows:—Each key, when depressed, lifts the horizontal arm of a driver lever, the vertical arm of which, by means of the driver finger, slides the shuttle to approximately the correct position opposite an impression hammer. The key simultaneously raises a vertical rod, which forms a stop pin, against which a horizontal arm connected with the shuttle strikes, thus arresting the shuttle in exactly the right position properly to print the symbol required. The same key also lifts a trip frame lever, the arm of which depresses an escapement lever, thus disengaging the pawl (connected to the hammer by a hammer lever) from the escapement wheel, and allowing the hammer spring to throw the hammer forward against the type presented by the shuttle, and impress on the paper held by the carriage the symbol desired. The inking is done by a travelling ribbon, and the blow of the hammer is distributed over the character by a rubber strip, while a thin metal mask with a central hole is provided, which prevents more than the intended symbol from being touched by the paper at each impression.

There are thirty-three keys arranged in two rows in a convex curve; two are used for lifting the shuttle-guide so as to bring any row of characters to the printing level, and a third for spacing between the words. The paper-holder is moved transversely by a spring that is re-wound by the return movement of the carriage, and is released for each letter by an escapement. The carriage is open at both ends, permitting of any width of paper being inserted with the greatest facility, the length of the written line only being limited.

The advantages offered by the "shuttle" principle of construction as embodied in the "Hammond" are visibility of the text, interchangeable type, and perfect permanent alignment. It is only necessary to be provided with different shuttles to be able to change the style whenever it may be desired; this is a simple and speedy operation. The manufacturers furnish upwards of over 200 different styles of type-shuttles in over 38 different languages, such as Greek, Hebrew, Arabic, German, Russian, Esperanto, &c., also a special Braille shuttle for the blind.

As in other modern typewriters, the depth between and length of lines are variable, while the facilities for making corrections and alterations are excellent. The tension of the main spring and hammer are adjustable for manifolding and stencilling.

The Hammond is made in two varieties, termed the "Ideal" and the "Universal." They differ only in the arrangement of the keyboard. The "Ideal" is semi-circular, and is to be preferred for the reason that it locates characters most frequently used in the centre of the shuttle, thereby increasing the speed and lessening the amount of wear. The

"Universal" has the standard or universal keyboard.

Features.—Double faced hammer, variable line spacer, back spacing device, bi-chrome ribbon. I am informed that developments in the near future will include a built-in decimal tabulator and a carriage to letter space either way, useful for western and eastern languages.

Blickensderfer.

The 84 types in this machine are set round the circumference of a wheel—there are 30 keys, two being shift-keys, one for "capitals" and the other for "figures, &c." The type-wheel can be changed in an instant for one of another style or language—over eighty-five styles are manufactured, covering ancient Greek, modern Greek, Servian, Russian, &c.

The type being in one piece, the relation of one letter to the other must always remain the same, and, therefore, the alignment remains unvaried after wear or when manifolding.

The inking device is a small ink roller swinging on a simple horizontal joint, which passes over the face of each character as it is presented to it.

The force of the impact of the type-wheel on the paper is dependent upon the operator, but whether light or heavy, a clean, sharp impression results, which imprint is semi-visible.

The line-spacing arrangement allows of any desired space between the lines from a hair-breadth to the full stretch it is capable of—thus the depth can be adjusted to suit ruled paper.

The free carriage is a convenience—it can be moved in either direction without releasing a catch or pulling against a tension spring. Different widths of carriages are obtainable. The machine is easily portable—the No. 7 (foolscap) when fastened down to a baseboard, weighs approximately 12 lbs.

Accessories.

The tendency of the times is to employ the typewriter whenever it is possible to do so. Special devices are from time to time invented to meet these extended uses. The most important of recent applications is to counting-house work for billing and book-keeping; this work alone has necessitated important modifications. In this direction the tabulator calls for review. The lack of a practical method enabling tabular matter to be typed with a rapidity equal to that of ordinary typing has long been felt to be a deficiency in typewriters. The invention of the tabulator has enormously increased the scope of the machine in this direction.

The tabulator is a device by means of which figures or words can be written in columns, without employment of the space-bar or carriage release lever, or any adjustment whatever of the carriage by hand. By its use the carriage may be set automatically at any point that may be required. At present this device is an accessory to most machines, but in the near future it *must* form an integral part of all machines, and further, enable the carriage to be automatically placed in a proper position to write numbers in correct relation to each other in columns, *i.e.*, units under units, tens under tens, and so on. The built-in tabulators of to-day, with but two exceptions, are deficient in this respect. The tabulator in either form does not interfere with the use of the machine for other work, such as correspondence, &c.

The tabulator was followed by the introduction of a bi-chrome (two colour) ribbon, and quite recently the Smith Premier Typewriter Company have advanced still further in this direction by introducing a tri-chrome (three colour) ribbon. By a simple movement (previously explained) it is possible to vary the colour of the impression instantaneously, so that credits, marginal notes, foot notes, and underscoring may be indicated in red or other colour preferred. One colour ribbons can be used if desired.

The machines embodying the parti-coloured ribbons and tabulator devices are generally known as "Invoicing" machines, and by simple arrangements, every phase—not only of correspondence, but also of counting-house and statistical work—can be accomplished, with an enormous saving of time. Items can be made on sheets which may be taken from the machine with absolute certainty that when re-inserted the subsequent entries will fall into their proper places.

The introduction of a perfect form of loose leaf book makes it possible for the day-book entries and invoice to be written simultaneously. The benefits claimed for this system are:—Great saving of time, as the invoice and day-book are written simultaneously. The bulk of the invoice can be written in black ink and the credits shown on the same invoices in red, which ensures clearness. The invoice sent to the customer is an exact duplicate of the entry made in the day-book. There is no waste of time in press-copying the invoice, as the day-book entry is an exact copy. The day-book is

always available for the ledger clerk, as the entries being made upon separate sheets, the posting and writing of the day-book can be proceeded with simultaneously. The type-written matter in the day-book does not occupy more than half the space that is used in an ordinary book written by hand. The loose leaf book affords a convenient means of binding typewritten documents of many kinds.

Card Indexing.

For greater convenience in card-indexing special platens are obtainable, or the ordinary platen can be temporarily fitted with a metal clip. Both can be fitted to or removed from the machine in a few seconds, and the cards can be adjusted in an instant. The increasing use of the card file system for a wide variety of purposes lends special importance to the value of the typewriter for this class of work.

Interchangeable Carriages.

For years the thousand and one wide forms, statements, and blanks common in every business office, have been filled by the pen, the reason being that there was no machine practicable for both wide and ordinary work. The manufacturers of most of the modern typewriters now have models embodying interchangeable carriages, which enable anyone possessing a machine with this improvement to have at the same time a set of carriages from the largest to the smallest, all of which can be used upon one machine. In one or two makes this is additional to interchangeable platens.

In this connection I might mention the titles and approximate sizes of paper accommodated by each of the varying models of modern typewriters. They are :—

Foolscap	approx.	9½	ins.
Draft	,,	11	,,
Brief..	,,	14	,,
Policy	,,	18	,,
Manifest	,,	27	,,

In each style of make and model they differ only in size and in one or two small details of construction necessitated by the greater length of the carriage.

Duplicators.

The value of a mechanical contrivance for the rapid and effective multiplication of copies of documents is, at the present time, so fully recognised, that little need be said by way of introduction.

Duplicating machines have been on the market for several years. Their merits as a time and labour saver have been widely appreciated. From time to time as experience proved desirable, various improvements have been made, and modern duplicators represent one of the most useful devices than can be installed in a commercial or professional office as an adjunct to the typewriter. They will produce from one typescript original up to 3,000 copies, of any size, from a post-card to a sheet of brief, every copy having the exact appearance of an original. As evidence of the truth of this statement, I need only state that the postal authorities specify that such copies must be handed in over the counter of a general or branch office, or at one of the authorised sub-offices, and special attention directed to their nature, to secure admission as a half-penny packet. The value of having at hand a duplicating apparatus of this capacity is incalculable. Not only does it save the time and expense incurred in sending to the printer, and obtaining and returning proofs, but there is the additional advantage of being able to supervise, personally, the work in progress. While there are various makes and styles of duplicators, the main principle is the same throughout.

The original is prepared by the now well-known stencil process, *i.e.*, by writing the matter required with a typewriter on a sheet of waxed paper. The pressure of the type expels the wax out of the paper and leaves openings through which the ink can penetrate In the Roneo rotary duplicator a metal frame supports a cylinder of thin, perforated steel. On the outer surface of the cylinder is stretched a linen ink-pad, and over this is placed the stencil. The pad is inked by a rubber roller resting in an ink receptacle suspended between the two sides of the framework. By means of a simple lever this roller can be brought into contact with the cylinder, and ink is thus supplied as required.

The cylinder is rotated by a handle. Paper fed into the machine is gripped by a rubber impression roller, which presses it against the stencil as the cylinder revolves, and the sheet, perfectly printed, is then automatically discharged on the other side.

The rotary can be fitted with three devices, viz., a simple contrivance which automatically feess the sheets into the machine, reducing hand labour to a minimum; an interleaver, which automatically drops an interleaving sheet as each copy is printed—thus permitting

of the use of highly glazed or very hard paper; a cyclometer for registering the number of copies.

The rotary system is far superior to the hand duplicators in the matter of speed, such a machine will print ten copies while the hand device prints one. There is no lost motion, a copy being printed and discharged at each revolution.

Press-Copying.

Every business man recognises the necessity of copying his typewritten letters. At the present time there are four methods of letter copying in vogue, viz.:—(1.) The letter-book method, damping sheets and screw press. (2.) Roller process, water bath and drying drum. (3.) Carbon paper. (4.) The chemical letter copier. The question to be decided is—which is the best method? In regard to the letter-book method, the great drawback is the difficulty of getting the right degree of moisture. Either too much or too little water is applied, and the result is either a smudged copy or one too faint to be readable.

The roller copiers employ a water bath, and give but little if any improvement in the regulation of the degree of moisture. The copies are wound upon a drying drum to prevent off-setting, and subsequently have to be cut apart for filing purposes.

The carbon process enables the answers to be filed with the original letter. But this method has its shortcomings; often at the last moment a correction is made in the answer, the correction in the carbon copy is overlooked, and hence an unreliable record arises. Again, the carbon may not exactly be positioned, and so a word or two at the margin is easily missed.

The modern chemical letter copier offers distinct advantages over the methods first explained. It consists of a simple machine designed to carry a roll of specially prepared paper. The letter to be copied is laid on the feed board, the handle is turned, the sheet is fed automatically into the machine. This is repeated as often as there are letters to be copied, the machine feeding in the sheet, making the copy and storing it on the roll. As many as ten copies (in succession) can be taken from one original. These are cut off with automatic precision and by one movement of the lever-knife.

It will be noticed that a water-bath and brush, or damping sheets are completely dispensed with; there is no "off-setting" and no drying drum. The copy may be either filed with the letter to which it relates or placed, day by day, in a cover having the appearance of an ordinary letter-book—or two copies can be made of each letter—one for filing and the other for the book. For the book method, the sheets are punched at the binding margin.

This brief survey of "modern typewriters" indicates clearly the conditions necessary to meet satisfactorily the average requirements, *i.e.*:—

1. It should be durable. Every part should be simple and strong and adapted to serve its purpose with the smallest degree of wear. Every mechanical movement must be definite, and incapable of incomplete performance. All wearing parts should be adjustable and interchangeable. The work should be performed by the smallest number of movements on the part of the operator, and these movements should be of the simplest and easiest character.

2. It should possess absolutely "visible" writing. The common-sense way to write easily and speedily is to see what you are writing while you are writing it. To be obliged to stop and lift a carriage, tilt a platen, or peer over or under constructional parts in order to see what has been written, checks both the work in hand and the progress of the thought. The writing should be performed in such a part of the machine as to be most readily seen during progress.

3. The keyboard—on type-bar machines in particular — should be that known as the "Universal" or "Standard" arrangement—an assortment which enables the hands to maintain a fairly regular alternate operation while giving the greatest possible speed.

If shift-keys are dispensed with, the keyboard should be condensed by being arranged in straight lines, up and down, right and left, and with the keys almost "flush" one with the other, so that the fingers can glide easily over the keyboard.

The keys on any style of keyboard should have a light and uniform depression, so that the machine may be operated with the minimum of fatigue, and, further, they should preferably be of a dull or neutral colour and present a concave surface to the finger tips. The resistance or tension should be adjustable at will—preferably independently instead of collectively.

4. The type should present an even and regular appearance, termed "alignment."

A type-bar made of suitable material in the right way is the keystone of typewriter con-

struction, for it must be remembered that a typewriter in the last analysis is but a type-bar (or type-wheel) and its attachments.

In all machinery there is some part upon which falls the greatest strain and wear; consequently, upon the durability of that part rests the life of the machine. In typewriters constructed upon the pivotal principle the greatest strain comes upon the bearing or pivot on which the type-lever or bar swings when moving to and from the printing point. If the bearing is absolutely without play the letters write in a perfectly even, straight line. If the bearing is faulty in design or becomes worn, the letters print unevenly and in a wobbly line.

It is well known to everyone that, no matter how good the quality of steel, all wearing surfaces will, if used continually, show signs of wear, therefore a good bearing should have mechanical means for adjustment to take up slack, caused by wear. To get a rigid bearing it is necessary to provide a wide bearing and a short type-bar.

The devices used to secure alignment are numerous and ingenious. One machine depends upon a wide pivotal bearing and a rigid type-bar; another has a bearing composed of a continuous steel rod, with a type-bar flexible while in motion, and made rigid at the printing point by means of guides; a third employs a wide pivotal bearing, a flexible type-bar and either guide pins or a guide plate at the printing point; a fourth employs a compound type-bar and an indispensable guide at the printing centre, and so on. Some have wide and adjustable bearings, to enable the wear to be taken up. These devices, however, are not the only essentials; the type-bar hangers in machines embodying the pivotal principle need to be rigid and solidly fixed, whilst the paper carriage should be perfectly rigid and present a level and even platen surface for the type to strike against.

5. The type should be capable of being easily and quickly cleaned, and in such a way as not to injure the type or soil the hands. Whether it should be wholly interchangeable depends upon the individual requirements.

Special type and corresponding key buttons to meet the extended uses of the typewriter are available. Manufacturers are, as a rule, in a position to supply promptly characters incidental to any commercial, literary, scientific, or medical work, as, *e.g.*, fractions, accents, and the like.

A device should be embodied for rendering it impossible to batter the face of the type when the type-bars are accidentally struck one against the other, and for preventing the type perforating or puncturing the platen.

6. The mechanism controlling the movement of the carriage should act rapidly and uniformly, and its tension should be adjustable. The carriage should have a sure and regular paper feed and be capable of accommodating any smaller width of paper; also the margin regulators and bell trip should be easily and readily altered. The carriage release should operate both from the right and left hand, and marginal releases and a line-looking device should be provided. A back spacer is a convenience. There should be no complicated mechanism to retard the quick insertion, adjustment, or withdrawal of the paper.

An adjustable left side guide is desirable, since it permits of the adjustment of the paper with absolute accuracy to any marginal indentation—useful in invoicing, card writing, &c. The carriage should accommodate several thicknesses of paper, so as not to crumple the sheets when it is desired to manifold. There should be a device for indicating when the bottom of the sheet is approached.

7. The platen roll should be instantly interchangeable, thereby allowing of a soft substance platen being used for single copy work and a hard one for manifolding. If the hard platen is of reduced diameter, more perfect alignment is secured on machines employing a complete circle of rigid type-bars and a central top carriage.

8. The line-spacing mechanism should be variable, and effected by one movement at all times, *i.e.*, the same movement that accomplishes the line feed should be utilised to return the carriage for a new line. A variable line-spacer is desirable, as such a device renders it possible to write at any point on the surface of the paper. It makes all corrections easy, whether or not the paper has been removed from the machine. The best form of variable line-spacer is that connecting directly on the cylinder independent of the ratchet detent. The life of the platen is prolonged, because the type no longer strike in unchanging grooves; each time the spacer is used the cylinder presents a new writing surface.

9. The ribbon movement (if the machine has a ribbon) should consist of a reliable feeding mechanism, and allow of the fabric being quickly withdrawn, replaced, or adjusted for

stencil work. It should bring the whole surface in contact with the type, and also automatically reverse the endwise travel. The ribbon should be capable of being easily attached to the spools without the aid of tapes and pins.

10. The machine should be as noiseless in operation as possible. Efforts are constantly being made to reduce the noise; rigidity of parts tends to eliminate shake and rattle. Machines differ very much in this particular. The employment of guides to force the alignment introduces metallic contact, and consequent friction and noise.

Before concluding my paper I wish to state that my mind is involuntarily carried back to the evening of May 1st, 1867, when Mr John Pratt, of Alabama, U.S.A. (but then residing in College-place, Camden-town, London) exhibited here and very ably described the construction and manipulation of two models of a very ingenious writing machine he had devised. In the course of the discussion a Mr. W. H. Bonnewell, in reply to the Chairman's request that a vote of thanks be given to this pioneer inventor, rose and said:—

"He hoped it would not go forth that in passing that vote of thanks to the author of the paper, the meeting endorsed the feasibility of the invention which had been brought before them. He would be sorry to throw any discouragement upon an ingenious invention; but having had some experience in these matters, he felt himself compelled to give an adverse verdict upon it. . . . He would therefore say, while he quite concurred in a vote of thanks being given for the great ingenuity displayed in the construction of the machine, at the same time if that vote was to be regarded as a verdict in favour of it, he should feel disposed to dissent."*

This is barely forty years ago, and the wonderful perfection of modern typewriters and their indispensable accessories speak volumes as to their utility and present day popularity; in fact, it is not a question of whether or not to use a writing machine, but rather which machine to use. Collectively, typewriters have scattered untold blessings on all civilised communities; they have created an honourable field of employment for thousands upon thousands of persons, either in offices or in the enormous factories devoted to their manufacture. The Society, by the institution of its typewriting examination in 1891, has done much for the large army of literary pianists by encouraging a high standard of work.

* See *Journal*, vol. xv., p. 384, also vol. xxiv., p. 245, and vol. liii., p. 921.

I thank you heartily for the very kind attention you have accorded me during the delivery of this humble paper, which, from its very nature, is somewhat technical and unattractive; still, if its recital has deepened your intimacy with machines for recording modern thought I feel that I am amply repaid for the time involved in its preparation.

I further desire to publicly thank the various typewriter companies for the valuable and willing assistance rendered to me in preparing and illustrating this paper.

After the reading of the paper there was an exhibition of modern typewriters, kindly lent by the various proprietors.

The following Type-bar Machines were shown:—Remington, Fay-Sholes, Smith Premier, Yost, Barlock, Salter, Underwood, Monarch, Ideal, Pittsburg, Visible, Empire, Oliver, Williams, and Fisher.

Type Wheel machines. Hammond and Blickensdorfe. (See Table, p. 431.)

Duplicators:—Gestetner Rotary Duplicator, Roneo Rotary Duplicator, and Roneo Chemical Copier.

The CHAIRMAN, in proposing a hearty vote of thanks to the author for his interesting paper, said that owing to the lateness of the hour it was impossible for any discussion to take place.

The resolution of thanks having been carried unanimously, the meeting terminated.

BRITISH RESULTS AT MILAN EXHIBITION.

It is stated that the Report on the British Section of the Milan International Exhibition of 1906 is now in course of preparation. The comparatively late period of the year at which the various sections were finally completed precluded an early *coup d'œil* of the exhibition as a whole, as well as of the relative importance of the British Section. There were 333 British exhibitors, and to these were accorded no fewer than 340 awards. The particular departments in which Great Britain is now acknowledged to have clearly excelled were the marine, where the ships' models contributed by the great firms on the Clyde and the Tyne attracted deserved admiration, the agricultural and textile machinery exhibits, the latter being a department in which we are likely to hold the premier place for some time to come. In respect of decorative arts, too, it is admitted that we have made an excellent display, especially in furniture, ceramics, glass, lace, jewellery, and engraving. The total number of exhibitors was 12,500, and an area of 250 acres was occupied by the exhibition. There were 5,500,000 of visitors altogether, and the admissions amounted to £175,000.

HOME INDUSTRIES.

Workmen's Compensation.—Most of the insurance companies have agreed to work together in domestic service insurance, and so to maintain adequate premium rates. It is the reasonable course, but it may be hoped that rates, whilst "adequate," will not be excessive. To fix unnecessarily high rates would be to encourage competition of an undesirable character. That occurred after the passing of the mother Act, with disastrous results. Experience is necessary to settle authoritatively the rate at which iusurance companies can safely ensure the domestic servant, but meantime the decision of what may be called the tariff offices as to the rate to be charged for the "casual" servant, such as the charwoman, seems open to criticism. The price asked for indemnity is an addition of 25 per cent. to the total premium, with a minimum of 2s. 6d. This seems excessive. For a servant working throughout the year from morning to night 2s. 6d. is considered adequate to cover the risk, and yet the small householder who calls in a charwoman now and again has to pay 2s. 6d. It is very doubtful whether the Act covers this class of service. It is certain that it makes the employer absolutely responsible for accidents to his regular domestics, but it is by no means certain that he is under any liability for persons only occasionally employed for other than trade or business purposes. At any rate, until the point has come before the Courts, as it must do when the Act is in operation, and claims begin to be made on behalf of the casual, it might be thought that the insurance companies would be content with a lower rate, and even if the Courts read the Act to cover the casual servant, the risk to one employed say upon 25 days of the year, or even 50, must be very much less than that incurred in the case of one employed on the whole 365 days of the year, yet, unless there is revision, it will cost as much to insure against loss upon the one class as the other.

The Profits of Colliery Companies.—At a time when the householder is grumbling at the high price of coal, and ruling rates have been exceptionally high throughout the winter, it may be interesting to note the profits of representative colliery companies, as shown by their balance-sheets for 1906. Eight of them dealing with last year have now been issued, and it would be strange if, in a year in which the export trade showed an excess of 8,433,000 tons over that of the preceding twelve months, and the activity of the iron trade and other industries made the home trade exceptionally good, exceptional profits were not shown. Accordingly the figures are very satisfactory from the coal owners point of view. The eight companies earned an aggregate profit of £464,107, as compared with £278,813 in 1905, the shareholders receiving dividends amounting to £253,338, as compared with £202,288 in 1905. It will be noted that the amount received by shareholders is small as compared with the profit earned, but the proportion is always small in colliery companies. It is, however, much smaller this year than last if the eight companies to whom the figures given above apply are taken as the basis of comparison. Out of last year's profit little more than half, or to be exact 54·6 per cent. goes to shareholders, in 1905, upon a much smaller aggregate profit, they got 72·6 per cent. The justification for the comparatively small proportion of profits distributed by colliery companies is the many contingencies that have to be provided for. An exceptional instance of the extent to which some colliery companies provide for contingencies is to be found in the case of a company with a share capital of £250,000, and a loan on mortgage for £45,000. There is a reserve fund standing at £45,000, depreciation account £123,983, dividend suspense account £25,000, and suspense account No. 2 £15,000, making a total of £208,983. The one unfavourable feature of the past year, from the point of view of the companies, was the rise in wages, but this increased expenditure was much more than counterbalanced by the rise in prices. The present year promises a continuance of the good times for colliery companies, and it may be hoped that they will not take extreme advantage of the position and so array public opinion ageint them.

Railways and Traders.—The dissatisfaction of traders with railway authorities has just found vigorous expression at a conference convened by the Manchester Committee on Railway and Canal Traffic, at which the following resolution was unanimously adopted:—"That in the opinion of this meeting the combination into which the railway companies have entered violates the conditions on which such companies have acquired their statutory powers, is contrary to public policy, in that it tends to destroy public competition, and is calculated, if maintained, to invest the railway companies with the uncontrolled monopoly of the carriage of merchandise; and this meeting thereby pledges itself to resist the policy of combination by all available means." A second resolution calls upon the Board of Trade to publish the terms of all such arrangements made by any railway companies with reference to merchandise traffic; and a third asks the President of the Board of Trade to receive a deputation, which, among other things, will urge the abolition of preferential rebates and arrangements, especially with regard to foreign imports. There can be no doubt that these resolutions express the strongly-held opinions of a large body of traders throughout the kingdom, but it is pointed out on the other side that there is no new general combination among the railways, but only certain agreements of a local character which aim at the restriction of unnecessary competition. Again, it is urged that even if the alleged combination did exist, the present powers of the Board of Trade, and of the

Railway and Canal Commission, are quite wide enough to prevent injustice being done to the traders, seeing that it is virtually impossible to raise rates, or even to restore those which have been reduced. Whatever the explanation, it is noteworthy that, although Section 31 of the Railway and Canal Traffic Act, 1888, provides that if any trader is of opinion that a railway company is treating him unfairly, or in an offensive manner, he may complain to the Board of Trade, the ninth report of the Board of Trade of proceedings under this section speaks of the "marked falling off" in the number of complaints against the railway companies.

Railways and Traders in Germany.—As bearing upon the above controversy, Mr. A. M. Ackworth lends his high authority to the support of the opinion that the German railways do not give German traders as good accommodation and service as the British trader gets here. The latter may pay more, and it is open to argument whether the extra advantages he enjoys are on the whole worth as much as, or more or less than, the extra price, if any; but these are separate questions on which, in the entire absence of statistical information in England, opinion can only be expressed with great hesitation and considerable reserve. What seems to be admitted is that there is more dissatisfaction with English than with German rates at the present time, and Mr. Ackworth's explanation comes under three heads. (1.) There has been a good many increases in English rates, indirect rather than direct, in recent years, but whilst the German State railways have recently increased their passengers fare very considerably such changes as they have made in freight rates have all been downwards. (2.) Changes in English rates are made privately and (practically) by the unchecked authority of the railways; in Germany only after full consultation with and notice to the districts and traders concerned. Mr. Ackworth is of the opinion that if the Board of Trade would secure the establishment of district and national railway councils on the German model it would confer a great advantage on the traders, and an even greater advantage on the railway companies. (3.) There is necessarily more discontent here than in Germany, because the English system is one of differential competitive rates. The German system is, speaking broadly, one of cast-iron distance rates. The discontent of the English trader, Mr. Ackworth argues, is a part of the price which he must be content to pay for our differential system, without which English trade would be paralysed.

Rubber Supplies.—Great as has been the increase in the demand in recent years for india-rubber, a demand likely to show continuous increase for many years to come, and notwithstanding the coming exhaustion of the available supply from the forests in the Amazon basin in South America, there is not much fear of the demand getting far ahead of the supply in the immediate future. Within a decade the rubber plantations in the Malay Archipelago, Ceylon, and elsewhere, planted in recent years, will be coming into full bearing, not to speak of the immense tracts likely to be planted during the continuance of high prices. And now comes a report from Mr. Dawe, the Government Botanist in the East African Protectorate, who announces the discovery in the forests of Uganda of large tracts where the Lagos silk rubber tree flourishes in great profusion. Mr. Dawe estimates that there are upwards of two millions of these trees on an area of some fifty-four square miles; the rubber being not much inferior in quality to that obtained from South America.

The Increase in the Cotton-spinning Mills.—The *Statist* gives some interesting figures showing the great increase in cotton-spinning mills during the past three years, and their effect upon other industries and wages. In the thirty years, 1870-1900, the increase in the number of spindles was only 6,300,000; since the commencement of the century, that is to say in seven years, the number of spindles in Great Britain has increased by 10,000,000. At the present time, the total number of spindles in France is only 7,000,000, and in Germany, including Austria and Switzerland, roughly 15,000,000. In the first year of the century mill flotation was almost at a standstill. Only four companies were registered, and of these two remained dormant until 1903. The following year eight companies were registered; in 1902 only two were formed. It was not until 1903 that the boom began. In that year ten large mill companies were registered, to be increased in 1904 by 16 other large mill companies; 1905 saw an addition of no less than 40 mill companies. Last year only 20 companies were formed, but the present year already sees 14 new large mill companies. Taking the five years 1903-7, 100 new mill companies, with a nominal capital of £8,330,000, have been formed; nor must the extensions of privately owned mills, representing a large number of spindles and capital, be forgotten. The immense extension of production suggested by these figures has made work for a great army of workpeople, male and female, something like 30,000 persons of both sexes, with an addition in wages bills of about £32,000 weekly for the additional 10,000,000 spindles. This money goes in turn, and for the most part, to shopkeepers, property owners, and places of amusement. The average of comfort is raised, and it may be mentioned that the number of operatives owning the houses they live in in Oldham, the centre of the cotton spining district, is very greatly in excess of the proportion living in their own houses in any other part of the Kingdom. And three out of every five Oldham families have savings invested in the mills they work in.

OBITUARY.

HERBERT MILLS BIRDWOOD, LL.D., C.S.I.—The Society of Arts and its Indian Section have suffered a severe loss in the sudden death of Mr. Birdwood at his residence at Twickenham, on the 21st February. On the 14th ult. Mr. Birdwood attended the meeting of the Indian Section when Sir Frederic Lely read his paper on Famine in India, and at the previous meeting of the Section in the absence of the author, he read Captain Barnes's paper on "The Bhils of Western India."

Mr. Birdwood was the third of five sons of General Christopher Birdwood, some time Commissary-General for Bombay. He thus belonged to the fourth generation of his family in the direct line officially connected with India from about 1760. He was born at Belgaum, in the Deccan, and was educated successively at Plymouth, Exeter, Edinburgh, and Cambridge. He graduated in the latter university in 1858 as a Wrangler, and in the second-class of the Natural Science Tripos. He sat in the first open competition which, in 1858, superseded nomination to Haileybury as a passport to the Indian Civil Service, and at the final examination stood eleventh on the list.

His first judicial charge was in the Konkarie district of Ratnagari, and in 1881 he was elevated to the position of Judicial Commissioner and Judge of the Sudar Court in Sind. He greatly distinguished himself in laying out the People's Park at Karachi, and Dr. John Pollen, in writing respecting Mr. Birdwood's paper on the Province of Sind, bore witness "to the devoted service Mr. Birdwood rendered in connection with the gardens and zoological collections at Karachi. . . . . Wherever he served he used to make gardens flourish, and he stimulated others to follow his example." (See *Journal* vol. li. p. 610.) After acting on three occasions as a Judge of the Bombay High Court, he was made a permanent member of the Bench in 1885, a position he continued to hold until appointed judicial member of the Bombay Government in 1892. He was a syndic of the Bombay University, and in four separate years he was Dean of the Arts Faculty. In 1891-92 he was Vice-Chancellor. In 1889, while home on leave, he took the degree of LL.D., and was called to the Bar at Lincoln's-inn.

Two years before his permanent return to England he acted as Governor of Bombay for a single day on February 17th, 1895.

He was elected a member of the Society of Arts in 1897, and he took great interest in its proceedings. He read a paper in 1898 on the Plague in Bombay, in battling with which calamity he had taken a prominent part. For this paper he was awarded the Society's medal. In 1903 he read the paper on the Province of Sind already alluded to.

A few years ago he obtained the distinction of election to the Honorary Fellowship of his old college—Peter-house. His was a busy life, and in the many occupations he was continually engaged, he gained the esteem and respect of all in whose company he was thrown from his attractive personal character and readiness to help others.

He leaves a widow and four sons, all serving in the Army in India, and one daughter, married to Colonel Stewart, R.A.

GENERAL JAMES MICHAEL, C.S.I. — General Michael, the first organiser of a scheme of Forest Conservancy in India, died at San Remo on the 17th February. He was born on the 2nd January, 1828, and, after commencing his education at Brighton, he studied in Germany, in Switzerland, and at the Military Academy, Edinburgh. He entered the army in December, 1844, as an ensign in the Madras Infantry. In 1848 he was appointed as assistant engineer to organise a scheme of forest conservancy, which he superintended until the establishment of a regular forest department in 1856. He was assistant chief engineer at Hyderabad during the Mutiny, and received a medal and the thanks of the Government of India for his services. On the occasion of the King's (then Prince of Wales) visit to Madras in 1875, General Michael was attached to His Royal Highness's staff. He was Secretary to the Government of Madras, military department from 1876 to 1883. General Michael was also Commissioner for several international and other exhibitions. He was elected a member of the Society of Arts in 1885, and as a member of the Indian Section Committee, he took great interest in the proceedings of the Society. On December 19th, 1894, he read a paper on Forestry, for which he received the Society's medal. In the discussion which followed the reading of the paper, Sir Clements Markham (who presided), Sir Joseph Fayrer, and Sir George Birdwood all spoke in the highest terms of the work done by General Michael for the establishment of forestry in India. In 1898 when a paper was read by the late Sir M. E. Grant-Duff on the "Recreations of an Indian Official," the author in reply to the vote of thanks moved by the Chairman, Lord George Hamilton (who had alluded to the fact that 1898 was the Jubilee year of the great Forest Department of India) said "that General Michael was a very distinguished forest officer and a pioneer of much good work in that direction."

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday Evenings, at 8 o'clock:—

MARCH 6.—"The Discovery of the South Eastern Coalfield." By PROFESSOR W. BOYD DAWKINS, D.Sc., F.R.S. The Right Hon. LORD HARRIS, G.C.S.I., G.C.I.E., will preside.

MARCH 13.—"Mediæval Stained Glass, its Production and Decay." By NOEL HEATON, B.Sc. LEWIS FOREMAN DAY, F.S.A., Vice-President of the Society, will preside.

MARCH 20.—"Smoke Prevention in Factories and Electric Supply Stations." By JOHN B. C. KERSHAW, F.I.C. SIR JOSEPH W. SWAN, M.A., F.R.S., will preside.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

MARCH 14.—"The City of Madras." By SIR JAMES THOMSON, K.C.S.I., M.A., late Member of Council, Madras. The LORD AMPTHILL, G.C.S.I., G.C.I.E., will preside.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

MARCH 5.—"British Malaya." By SIR WILLIAM HOOD TREACHER, K.C.M.G., M.A. (Oxon), late Resident General Federated Malay States. SIR FRANK SWETTENHAM, K.C.M.G., will preside.

APPLIED ART SECTION.

Tuesday evenings, at 8 o'clock:—

MARCH 19.—"Oils, Varnishes and Mediums used in the Painting of Pictures." By A. P. LAURIE, M.A., Principal of the Heriot-Watt College, Edinburgh.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

F. HAMILTON JACKSON, "Romanesque Ornament." Three Lectures.

LECTURE II.—MARCH 4.—Italian examples of Romanesque ornament—Byzantine art and its formation—Patterns suggested by textiles—Arab influence—Byzantine influence in Italy mixed with Lombard—Archaistic stucco work, affected by Byzantine ivories—Classical motifs copied—Decorative arcadings at Venice and Verona.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 4...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. F. Hamilton Jackson, "Romanesque Ornament." (Lecture II.)

Engineers, in the Theatre of the United Service Institution, Whitehall, S.W.. 7½ p.m. Mr. Edward John Stead, "The Connaught Bridge, Natal."

Victoria Institute, 8, Adelphi-terrace, W.C., 4½ p.m. Mr. C. W. Odling, "Orissa; its History and People."

Chemical Industry (London Section), in the Chemical Society's Rooms, Burlington-house, W., 8 p.m. Prof. R. Trelfall, "Measuring and Testing Producer Gas."

Asiatic, 22, Albermarle-street, W., 3 p.m.

TUESDAY, MARCH 5...SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Colonel Section.) Sir William Hood Treacher, "British Malaya."

Royal Institution, Albemarle-street, W., 3 p.m. Professor W. Stirling, "The Visual Apparatus of Man and Animals." (Lecture IV.)

Alpine Club, 23, Savile row, W., 8.½ p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. Discussion on Mr. Dugald Clerk's paper, "The Limits of Thermal Efficiency in Internal Combustion Motors," 2. Mr. A. P. Trotter, "The Construction of Overhead Electric Transmission Lines."

Pathological, 20, Hanover-square, W., 8½ p.m.

Zoological, 3, Hanover-square, W., 8½ p.m.

Horticultural, Vincent-square, Westminster, S.W., 3 p.m. Rev. Prof. G. Henslow, "The True Darwinism."

WEDNESDAY, MARCH 6..SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Prof. W. Boyd Dawkins, "The Discovery of the South-Eastern Coalfield."

African Society, Criterion Restaurant, Piccadilly, W., 8 p.m.

United Service Institution, Whitehall, S.W., 3 p.m. Mr. J. Corbett, "The Strategical Value of Speed in Battleships."

Royal Archæological Institution, 20, Hanover-square, W., 4 p.m. The Rev. E. S. Dewick, "Consecration Crosses."

Obstetrical, 20, Hanover-square, W., 8 p.m.

THURSDAY, MARCH 7...Aeronautical Society (at the HOUSE OF THE SOCIETY OF ARTS), John-street, Adelphi, W.C., 8 p.m.

Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Miss N. F. Layard, "The Development of the Frog." 2. Mr. S. W. Kemp, "Biscayan Plankton Decapoda." 3. Professor E. B. Poulton, "A Special Point on Colour Adjustment of Chamæleon." 4. Mr. G. Claridge Dance, "New Channel Island Plants."

Chemical, Burlington-house, W., 8½ p.m. 1. Messrs. M. Barrowcliff and F. B. Power, "The Constitution of Chaulmoogric and Hydnocarpic Acids." 2. Messrs. H. M. Dawson and C. G. Jackson, "Volume Changes which accompany Transformations in the System $Na_2S_2O_3$: $5H_2O$."

Royal Institution, Albemarle-street, W., 3 p.m. Dr. W. Martin, "Old Dutch Paintings and Painters." (Lecture II.)

Civil and Mechanical Engineers, Caxton-hall, Westminster, S.W., 8 p.m. Mr. C. R. Allensby, "Types of Enclosed Steam Water Heaters."

Electrical Engineers, 25, Great George-street, S.W., 8 p.m., Mr. J. S. Highfield, "The Transmission of Electrical Energy by Direct Current on the Series System."

FRIDAY, MARCH 8...Royal Institution, Albemarle-street, W., 9 p.m. Prof. D. J. Hamilton, "Certain Seasonal Diseases of the Sheep, and the means of preventing them."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Mr. A. T. Arnall, "Corrugations on Tram-Rails."

Astronomical, Burlington-house, W., 8 p.m.

Clinical, 20, Hanover-square, W., 8½ p.m.

Physical, Physics Laboratory of the Royal College of Science, Imperial Institute-road, South Kensington, S.W., 8 p.m. 1. Prof. Trouton and Mr. Russ, "The Rate of Recovery of Residual Charge in Electric Condensers." 2. Mr. Pichon, "Experimental Mathematics." 3. Mr. Blakesley, "An Instrument to Describe Families of Equiangular Spirals." 4. Mr. Roberts, "A Micromanometer."

SATURDAY, MARCH 9...Royal Institution, Albemarle-street, W., 3 p.m. Prof. J. J. Thomson, "Röntgen, Cathode, and Positive Rays." (Lecture IV.)

Journal of the Society of Arts.

No. 2,833. VOL. LV.

FRIDAY, MARCH 8, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MARCH 11, 8 p.m. (Cantor Lecture.) F. HAMILTON JACKSON, "Romanesque Ornament." (Lecture III.)

WEDNESDAY, MARCH 13, 8 p.m. (Ordinary Meeting.) NOEL HEATON, B.Sc., "Mediæval Stained Glass, its Production and Decay."

THURSDAY, MARCH 14, 8 p.m. (Indian Section.) SIR JAMES THOMSON, K.C.S.I., M.A., "The City of Madras."

Further details of the Society's meetings will be found at the end of this number.

EXAMINATIONS.

The Society's Examinations will commence on Monday, April 15.

The last day for receiving applications from Local Committees is Tuesday, the 12th March, 1907, and after that date none will be received under any circumstances whatever. Application forms from the Provinces should therefore be posted not later than Monday, the 11th March. Committees may, however, close their entry lists at an earlier date, if found desirable.

Copies of the Programme for 1907, with full details, together with the questions for 1906, and reports by the Examiners, can be had, price 3d. (post-free 4d.) on application to the Secretary, Sir Henry Trueman Wood, Society of Arts, Adelphi, London, W.C.

The questions for the years 1900, 1902, 1903, 1904, and 1905 can also be obtained (price 4d. each year post-free) on application as above.

CANTOR LECTURES.

On Monday evening, March 4th, Mr. F. HAMILTON JACKSON, Vice-President of the Society of Designers, delivered the second lecture of his course on "Romanesque Ornament."

The lectures will be published in the *Journal* during the summer recess.

COLONIAL SECTION.

Tuesday afternoon, March 5, 1907; SIR FRANK SWETTENHAM, K.C.M.G., in the chair. The paper read was "British Malaya," by SIR WILLIAM HOOD TREACHER, K.C.M.G., M.A.

The paper and report of the discussion will be published in a future number of the *Journal*.

PRIZE FOR INDUSTRIAL HYGIENE.

The Council of the Society of Arts are prepared to award, under the terms of the Benjamin Shaw Trust, a Gold Medal, or a prize of £20.

The medal, under the conditions laid down by the testator, is to be given "For any discovery, invention, or newly-devised method for obviating or materially diminishing any risk to life, limb, or health, incidental to any industrial occupation, and not previously capable of being so obviated or diminished by any known and practically available means."

Intending competitors should send in descriptions of their inventions not later than December 31st, 1907, to the Secretary of the Society of Arts, Adelphi, London, W.C.

Such descriptions may be sent in under the inventor's name, or under a motto, accompanied by a sealed envelope enclosing the name, as preferred.

The Judges will be appointed by the Council.

The Council reserve the right of withholding the prize or of awarding a smaller prize or smaller prizes, if in the opinion of the Judges nothing deserving the full award is sent in.

THE ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal for 1907 early in May next, and they, therefore, invite members of the Society to forward to the Secretary, on or before Saturday the 6th April, the names of such men of high distinction as they may think worthy of this honour. The medal was struck

to reward "distinguished merit in promoting Arts, Manufactures, and Commerce," and has been awarded as follows in previous years:—

In 1864, to Sir Rowland Hill, K.C.B., F.R.S., "for his great services to Arts, Manufactures, and Commerce, in the creation of the penny postage, and for his other reforms in the postal system of this country, the benefits of which have, however, not been confined to this country, but have extended over the civilised world."

In 1865, to his Imperial Majesty, Napoleon III., "for distinguished merit in promoting, in many ways, by his personal exertions, the international progress of Arts, Manufactures, and Commerce, the proofs of which are afforded by his judicious patronage of Art, his enlightened commercial policy, and especially by the abolition of passports in favour of British subjects."

In 1866, to Michael Faraday, D.C.L., F.R.S., "for discoveries in electricity, magnetism, and chemistry, which, in their relation to the industries of the world, have so largely promoted Arts, Manufactures, and Commerce."

In 1867, to Mr. (afterwards Sir) W. Fothergill Cooke and Professor (afterwards Sir) Charles Wheatstone, F.R.S., "in recognition of their joint labours in establishing the first electric telegraph."

In 1868, to Mr. (afterwards Sir) Joseph Whitworth, LL.D., F.R.S., "for the invention and manufacture of instruments of measurement and uniform standards by which the production of machinery has been brought to a state of perfection hitherto unapproached, to the great advancement of Arts, Manufactures, and Commerce."

In 1869, to Baron Justus von Liebig, Associate of the Institute of France, For. Memb. R.S., Chevalier of the Legion of Honour, &c., "for his numerous valuable researches and writings, which have contributed most importantly to the development of food economy and agriculture, to the advancement of chemical science, and to the benefits derived from that science by Arts, Manufactures, and Commerce."

In 1870, to Vicomte Ferdinand de Lesseps, Member of the Institute of France, Hon. G.C.S.I., "for services rendered to Arts, Manufactures, and Commerce, by the realisation of the Suez Canal."

In 1871, to Mr. (afterwards Sir) Henry Cole, K.C.B., "for his important services in promoting Arts, Manufactures, and Commerce, especially in aiding the establishment and development of International Exhibitions, the Department of Science and Art, and the South Kensington Museum."

In 1872, to Mr. (afterwards Sir) Henry Bessemer, F.R.S., "for the eminent services rendered by him to Arts, Manufactures, and Commerce, in developing the manufacture of steel."

In 1873, to Michel Eugène Chevreul, For. Memb. R.S., Member of the Institute of France, "for his chemical researches, especially in reference to saponification, dyeing, agriculture, and natural history, which for more than half a century, have exercised a wide influence on the industrial arts of the world."

In 1874, to Mr. (afterwards Sir) C. W. Siemens, D.C.L., F.R.S., "for his researches in connection with the laws of heat, and the practical applications of them to furnaces used in the Arts; and for his improvements in the manufacture of iron; and generally for the services rendered by him in connection with economisation of fuel in its various applications to Manufactures and the Arts."

In 1875, to Michel Chevalier, "the distinguished French statesman, who, by his writings and persistent exertions, extending over many years, has rendered essential services in promoting Arts, Manufactures, and Commerce."

In 1876, to Sir George B. Airy, K.C.B., F.R.S., Astronomer Royal, "for eminent services rendered to Commerce by his researches in nautical astronomy and in magnetism, and by his improvements in the application of the mariner's compass to the navigation of iron ships."

In 1877, to Jean Baptiste Dumas, For. Memb. R.S., Member of the Institute of France, "the distinguished chemist, whose researches have exercised a very material influence on the advancement of the Industrial Arts."

In 1878, to Sir Wm. G. Armstrong (afterwards Lord Armstrong), C.B., D.C.L., F.R.S., "because of his distinction as an engineer and as a scientific man, and because by the development of the transmission of power—hydraulically—due to his constant efforts, extending over many years, the manufactures of this country have been greatly aided, and mechanical power beneficially substituted for most laborious and injurious labour."

In 1879, to Sir William Thomson (now Lord Kelvin), O.M., LL.D., D.C.L., F.R.S., "on account of the signal service rendered to Arts, Manufactures, and Commerce, by his electrical researches, especially with reference to the transmission of telegraphic messages over ocean cables."

In 1880, to James Prescott Joule, LL.D., D.C.L., F.R.S., "for having established, after most laborious research, the true relation between heat, electricity, and mechanical work, thus affording to the engineer a sure guide in the application of science to industrial pursuits."

In 1881, to August Wilhelm Hofmann, M.D., LL.D., F.R.S., Professor of Chemistry, in the University of Berlin, "for eminent services rendered to the Industrial Arts by his investigations in organic chemistry, and for his successful labour in promoting the cultivation of chemical education and research in England."

In 1882, to Louis Pasteur, Member of the Institute of France, For. Memb. R.S., "for his researches in connection with fermentation, the preservation of wines, and the propagation of zymotic diseases in silkworms and domestic animals, whereby the arts of wine-making, silk production, and agriculture have been greatly benefited."

In 1883, to Sir Joseph Dalton Hooker, K.C.S.I., C.B., M.D., D.C.L., LL.D., F.R.S., "for the eminent services which, as a botanist and scientific traveller, and as Director of the National Botanical Department, he has rendered to the Arts, Manufactures, and Commerce by promoting an accurate knowledge of the floras and economic vegetable products of our several colonies and dependencies of the Empire."

In 1884, to Captain James Buchanan Eads, "the distinguished American engineer, whose works have been of such great service in improving the water communications of North America, and have thereby rendered valuable aid to the commerce of the world,"

In 1885, to Mr. (afterwards Sir) Henry Doulton. "in recognition of the impulse given by him to the production of artistic pottery in this country."

In 1886, to Samuel Cunliffe Lister (afterwards Lord Masham), "for the services he has rendered to the textile industries, especially by the substitution of mechanical wool combing for hand combing, and by the introduction and development of a new industry —the utilisation of waste silk."

In 1887, to HER MAJESTY QUEEN VICTORIA, "in commemoration of the progress of Arts, Manufactures, and Commerce throughout the Empire during the fifty years of her reign."

In 1888, to Professor Hermann Louis Helmholtz, For. Memb. R.S., "in recognition of the value of his researches in various branches of science and of their practical results upon music, painting, and the useful arts."

In 1889, to John Percy, LL.D., F.R.S., "for his achievements in promoting the Arts, Manufactures, and Commerce, through the world-wide influence which his researches and writings have had upon the progress of the science and practice of metallurgy."

In 1890, to Dr. (now Sir) William Henry Perkin, F.R.S., "for his discovery of the method of obtaining colouring matter from coal tar, a discovery which led to the establishment of a new and important industry, and to the utilisation of large quantities of a previously worthless material."

In 1891, to Sir Frederick Abel, Bart., G.C.V.O., K.C.B., D.C.L., D.Sc., F.R.S., "in recognition of the manner in which he has promoted several important classes of the Arts and Manufactures, by the applicatiou of Chemical Science, and especially by his researches in the manufacture of iron and of steel; and also in acknowledgment of the great services he has rendered to the State in the provision of improved war material, and as Chemist to the War Department."

In 1892, to Thomas Alva Edison, "in recognition of the merits of his numerous and valuable inventions, especially his improvements in telegraphy, in telephony, and in electric lighting, and for his discovery of a means of reproducing vocal sounds by the phonograph."

In 1893, to Sir John Bennet Lawes, Bart., F.R.S., and Sir Henry Gilbert, Ph.D., F.R.S., "for their joint services to scientific agriculture, and notably for the researches which, throughout a period of fifty years, have been carried on by them at the Experimental Farm, Rothamsted."

In 1894, to Sir Joseph (now Lord) Lister, F.R.S., "for the discovery and establishment of the antiseptic method of treating wounds and injuries by which not only has the art of surgery being generally promoted, and human life saved in all parts of the world, but extensive industries have been created for the supply of materials required or carrying the treatment into effect."

In 1895, to Sir Isaac Lowthian Bell, Bart., F.R.S., "in recognition of the services he has rendered to Arts, Manufactures, and Commerce by his metallurgical researches and the resulting development of the iron and steel industries."

In 1896, to Prof. David Edward Hughes, F.R.S., "in recognition of the services he has rendered to Arts, Manufactures, and Commerce, by his numerous inventions in electricity and magnetism, especially the printing telegraph and the microphone."

In 1897, to George James Symons, F.R.S., "for the services he has rendered to the United Kingdom by affording to engineers engaged in the water supply and the sewage of towns a trustworthy basis for their work, by establishing and carrying on during nearly forty years systematic observations (now at over 3,000 stations) of the rainfall of the British Isles, and by recording, tabulating, and graphically indicating the results of these observations in the annual volumes published by himself."

In 1898, to Professor Robert Wilhelm Bunsen, M.D., For. Memb. R.S., "in recognition of his numerous and most valuable applications of Chemistry and Physics to the Arts and to Manufactures."

In 1899, to Sir William Crookes, F.R.S., "for his extensive and laborious researches in chemistry and in physics; researches which have, in many instances, developed into useful practical applications in the Arts and Manufactures."

In 1900, to Henry Wilde, F.R.S., "for the discovery and practical demonstration of the indefinite increase of the magnetic and electric forces from quantities indefinitely small, a discovery now used in all dynamo machines; and for its application to the production of the electric search-light, and to the electro-deposition of metals from their solutions."

In 1901, to HIS MAJESTY THE KING, "in recognition of the aid rendered by His Majesty to Arts, Manufactures, and Commerce during thirty-eight years' Presidency of the Society of Arts, by undertaking the direction of important exhibitions in this country and the executive control of British representation at International Exhibitions abroad, and also by many other services to the cause of British Industry."

In 1902, to Professor Alexander Graham Bell, "for his invention of the Telephone."

In 1903, to Sir Charles Augustus Hartley, K.C.M.G., "in recognition of his services, extending over 44

years, as Engineer to the International Commission of the Danube, which have resulted in the opening up of the navigation of that river to ships of all nations, and of his similar services, extending over 20 years, as British Commissioner on the International Technical Commission of the Suez Canal."

In 1904, to Walter Crane, "in recognition of the services he has rendered to Art and Industry by awakening popular interest in Decorative Art and Craftsmanship, and by promoting the recognition of English Art in the form most material to the commercial prosperity of the country."

In 1905, to Lord Rayleigh, O.M., D.C.L., Sc.D., F.R.S., "in recognition of the influence which his researches directed to the increase of scientific applications, the production of improved lenses, and the development of apparatus for Sound Signalling at Sea."

In 1906, to Sir Joseph Wilson Swan, M.A., D.Sc., F.R.S., "for the important part he took in the invention of the incandescent electric lamp, and for his invention of the carbon process of photographic printing."

PROCEEDINGS OF THE SOCIETY.

THIRTEENTH ORDINARY MEETING.

Wednesday, MARCH 6th, 1907; The RIGHT HON. LORD HARRIS, G.C.S.I., G.C.I.E., in the chair.

The following candidates were proposed for election as members of the Society:—

Cadell, Alan, C.S.I., Glenmara, Arthur-road, Wimbledon-park, S.W.
Conradi, Henry, 19, Ebbsfleet-road, Cricklewood, N.W.
Davies, Charles J., Milford Haven.
Fuller, George W., 170, Broadway, New York City, U.S.A.
Hayward, William Wyatt, 257 España, Lomas de Zamora, Buenos Ayres, Argentine Republic.
Midhut, Mohamed Hossain Khan, Office of Railway Board, Simla, and Zamania, Ghazipur District, U.P., India.
Myer, Reginald, 8, Ladbroke-square, W.
O'Brien, Hon. W. Turlough, 13, Egerton-place, S.W.
Ogilvie, Alec., 13, Holland-villas-road, Kensington, W.
Silberrad, Ch. A., B.A., B.Sc., care of Messrs. R. Silberrad and Son, 25, Savage-gardens, Crutched-friars, E.C., and Banda, U.P., India.
Testa, F. J., Honolulu, Hawaiian Islands.

The following candidates were balloted for and duly elected members of the Society:—

Aiyar, Narayana P. Hara, Local Fund Engineer, Anantapoor, Madras, India.
Alston, John, 88, Bishopsgate-street Within, E.C.
Clarke, His Honour Judge R. Johnson, 189, Broad-street, Monrovia, Liberia, West Africa.
Harward, Francis Vernon, 83, Dartmouth-road, Cricklewood, N.W.
Healey, Alfred E., 35, Marlborough-hill, N.W., and Constitutional Club, Northumberland - avenue, W.C.
Knowles, George Potter, Assoc.M.Inst.C.E., F.S.I., 39, Victoria-street, S.W.
Rutherford, Hon. A. C., Strathcona, Alberta, Canada.

THE DISCOVERY OF THE SOUTH-EASTERN COALFIELD.

By PROFESSOR W. BOYD DAWKINS, M.A., D.Sc. OXON, F.R.S.

The discovery of the south-eastern coalfield, between Dover and Canterbury, is one of those events which are closely connected with our industrial development, and which promises, in the not very remote future, to bring about the same changes in South Eastern England, as those following similar discoveries in France and Belgium in the nineteenth century. The story of the discovery is full of interest, and not merely from the commercial standpoint. It is the story of a scientific idea, originated many years ago, taking root in the minds of geologists, developed into theory, and ultimately verified by facts. It is a striking instance of the scientific imagination in advance of the facts, starting from the basis of past experience. The idea has been the centre around which the facts have clustered until, from our point of view of to-day, it appears as a strict induction without trace of *a priori* reasoning.

The Theory of Godwin-Austen.—The physical identity of the coalfields of Somerset on the west with those of Northern France and Belgium on the east was fully recognised by Buckland and Conybeare as far back as 1826. It was not, however, until 1856, that the idea of the existence of buried coalfields in South-Eastern England was advanced by Godwin-Austen, in a memorable paper* read before the Geological Society of London.

He pointed out that the coal seams are vegetable accumulations on flat alluvial marshes close to the water line, and extending over an enormous area, somewhat like that

* "On the Possible Extension of the Coal Measures beneath the South Eastern part of England."

in the lower courses of the Missisippi or the Ganges. The rocks which now cover the seams of coal, and contribute to build up a thickness of from 8,000 to 10,000 feet of coal measures, are merely sand banks and mud banks, accumulated during a period of depression, like that by which the submarine forests on our shores are covered by similar accumulations. At the close of the carboniferous age, these coal-bearing alluvia were thrown into a series of folds by earth movements, traceable at this time all the world over. The upper folds (anticlines) have for the most part been destroyed by rain, rivers, frost, and other sub-aerial agents, as well as by the dash of the waves on the shore line, while the lower folds (synclines) have been preserved by their position below the surface from the operation of the above-named destructive agents. These constitute coalfields more or less isolated from one another by areas of pre-carboniferous rock, exposed by denudation. Great lines of smashing and dislocation were also developed at the same time, and in the interval between the formation of the coal measures and the strata which overlie them, the destruction of the upper curves of the folded rocks has been effected. He next proceeded to show that these folds, running east and west, were the cause of the general direction of the exposed coalfields in South Wales and Somerset on the west, and of the Belgian and north French coalfields on the east, parallel to a great line of disturbance, which he termed the "axis of Artois," which he traced from the South of Ireland, through South Wales and North Somerset, into Westphalia. To the north of this the exposed coalfields lie in long, more or less narrow, east and west, troughs.

Before the deposition of the newer strata, the faulted and folded carboniferous and pre-carboniferous rocks, constituting the axis of Artois, formed a barrier which gradually sank beneath the sea of the Triassic, Liassic, Oolitic, and Cretaceous ages. Against this ridge the newer rocks gradually thinned off until in France the chalk rests on the coalfield over a wide area without intervening strata. This ridge or barrier also, where it is concealed by the newer rocks, is marked by the arch-like fold of the chalk of Wiltshire, and by the line of the north downs in Surrey and Kent. Godwin-Austen finally concluded, from all these observations, that there are coalfields beneath the Oolitic and Cretaceous rocks in the South of England, and that they are near enough to the surface, along the line of the ridge, to be workable. These original views gradually became part of the general body of geological theory. They were, however, not accepted by Sir Roderick Murchison, the then head of the Geological Survey, who maintained, to the last, that there were no valuable coalfields in South-Eastern England.

The Report of the Coal Commission, 1866-71.

The next stage in the development of the question is marked by the Coal Commission of 1866-71, before whom Godwin-Austen gave evidence. Prestwich was one of the Commissioners, and to him we owe an elaborate report, in which he fortified the views of Godwin-Austen by a large series of observations, and finally concluded that valuable coalfields, like those of Somerset, and of North France, and of Belgium, do exist beneath the newer rocks of the South of England, and that the same coal measures, which disappear in the west under the newer rocks of Somerset, reappear in the east, on the Continent, from underneath the same rocks, to the north of the ridge or axis of Artois. He considered them a chain of long, narrow, and isolated, coal troughs, with their position so concealed beneath the newer rocks that it can only be ascertained by experiment. The report materially helped to bring Godwin-Austen's theory to the test of experiment.

The Experimental Stage.

The Boring at Netherfield.—This report was published in 1871. In the following year the Sub-Wealden Exploration Committee was organised by the late Mr. Henry Willett, to ascertain the strata below the Weald of Sussex by an experimental boring. The site, chosen by the writer, was Netherfield, about three miles south of Battle, where the lowest rocks of the Purbeck Wealden formation constitute the bottom of the valley. The work was carried on under considerable difficulties, and it had to be abandoned in 1875. The rocks penetrated were as follows:—

Section at Netherfield.

	Feet.
Purbeck strata	200
Portland strata	57
Kimmeridge clay	1,073
Corallian beds	3'5
Oxford clay	60
	1,905

coalfield lies buried under the newer rocks in South-Eastern England, Godwin-Austen's theory, advanced in 1856, has resulted in adding a new coalfield to the mineral wealth of Great Britain. The question has been finally settled from the geological point of view. It is now being dealt with from the industrial side, by the sinking of shafts by the Kent Collieries Corporation.

The newer rocks covering the coal-measures traversed in the two shafts sunk near the borehole, according to Etheridge, are nearly eleven hundred feet thick as shown below.

Secondary Rocks concerning the Coal Measures in the Dover Shafts.

	Depth Below O.D. ft	in		Thickness ft	in.

Lower greensand..	373	8	..	123	8
Purbeck-Wealden beds ..	460	6	..	86	10
Oolites	1,060	6	..	600	0
Lias	1,097	6	.	37	0

The Extension of the Coal Measures north of Dover.—In 1897 borings were begun by various companies in other areas to test the range of the South-Eastern coalfield. In that year the Kent Collieries Corporation began to sink shafts at Shakespeare Cliff, and to put down boreholes at Brabourne and Pluckley, near Ashford. The Mid-Kent Coal Syndicate also put down a boring at Penshurst, and the Kent Coal Exploration Company began work in various districts under my supervision, with the important result that the coalfield was proved some eight miles away from Dover, at Ropersole (Figs. 1, 2, 3B), close to the high road to Canterbury.

This boring was carried out in 1897-9, with the assistance of Mr. James Newton, engineer in charge. It began at 400 ft. above O.D., at a spot where a thin layer of clay with flints formed the surface. It penetrated the following strata —

	Depth ft.	in		Thickness ft	in
Chalk and chloritic marl ..	834	0	..	834	0
Gault	953	0	..	119	0
Lower greensand	1,025	0	..	72	0
Oolites	1,553	0	..	473	0
Lias	1,580	9	.	27	9
Coal measures with coal seams	2,129	0	..	548	3

* The figures in the Table down to the Lower Greensand are taken from the Simpson shaft, and those below are taken from the Brady shaft. Etheridge's Section, Royal Commission on "Coal Supplies," Part IX, Appendix 5.

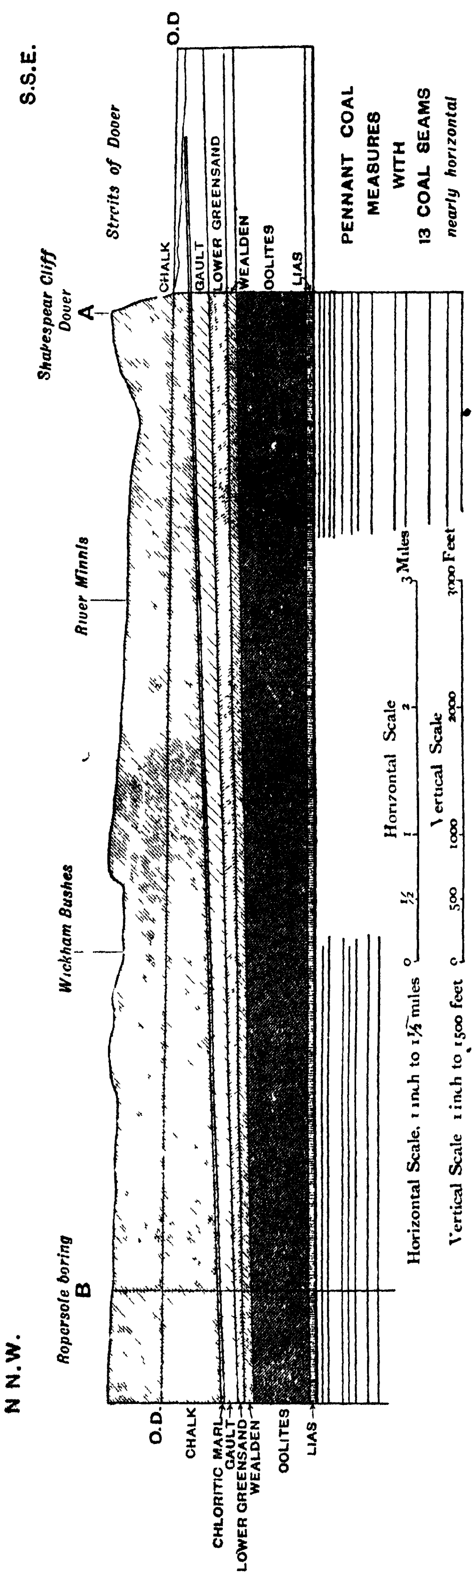

FIG. 2.—SECTION SHOWING PROBABLE ARRANGEMENT OF STRATA BETWEEN DOVER AND ROPERSOLE.

The coal-measures were struck at 1,180 ft. below O.D., and are practically horizontal. They contain thin seams of bright blazing coal, the two thickest being respectively 13 in. at 1,492 ft. below O.D., and 15 in. at 1,665 ft. below O.D. In my opinion they belong to the same series as those at Dover, characterised by the predominance of Sandstones. The approximate horizontality of the strata may be accounted for by the view that they lie in both places in the trough of a fold or syncline ranging from Dover to Ropersole, and beyond along the line of section (Fig 2). This conclusion is much more probable than the view that they extend horizontally over a very large area. It is also strengthened by further evidence from borings, as we shall see, to the south-west and north-east of a line joining the Dover and Ropersole borings.

The Boring at Ellinge.—The Ropersole boring proves the range of the south-eastern coalfield for more than eight miles north of Dover. The field is extended to the west by a further boring at Ellinge, carried out by the Dover Coal Extension Company in 1901-2, under the supervision of M. Breton. The coal-measures were struck at 1,686 ft. 4 in. from the surface, or 1,286 feet below O.D. They were, however, only penetrated to a depth of 129 ft. 4 in. without meeting seams of coal.

Section at Ellinge.

	Depth. ft.	in.	Thickness. ft.	in.
Chalk and chloritic marl	574	2	574	2
Gault	758	6	184	4
Lower greensand	797	3	38	9
Purbeck-Wealden	927	2	109	11
Oolites	1,632	3	705	1
Lias	1,686	4	54	1
Coal measures	1,815	8	129	4

The coal-measures consisted of Sandstones and Shales, approximately horizontal, and probably, like those at Dover and Ropersole, are near the bottom of the synclinal fold of the strata.

The Western Limit of the Coalfield indicated by the Boring at Brabourne.

It remains now to be seen how far the range of the south-eastern coalfield has been proved by other borings. None of the three begun in 1898 by the Kent Coal Exploration Company at Ottinge, Hothfield, and Old Soar, to the north of Tonbridge, have been carried deep enough to give any evidence. We are, however, indebted to Mr. Etheridge for conclusive proof that the south-western boundary does not extend as far to the south-west as Brabourne. There, in a boring made by the Kent Coal Collieries Corporation, a fine-grained, grey, Argillaceous Sandstone, in my opinion Devonian, or Old Red Sandstone, was struck at a depth of 1,921 ft, 5 in. from the surface, the strata being inclined at an angle of 60°, and being covered by a Red Dolomitic conglomerate, of Triassic age, just as in the central axes of the Mendip Hills, to the south of Banwell, and elsewhere.

Section of Boring at Brabourne.

	Depth. ft.	in.	Thickness. ft.	in.
Gault*	72	6	68	10
Lower greensand	303	6	231	6
Purbeck-Wealden	706	8	403	2
Oolites	1,701	8	995	0
Lias	1,873	5	161	9
Triassic conglomerate	1,921	5	48	0
Devonian or old red sandstone	2,004	0	82	7

The high dip of the Devonian or Old Red Sandstone rocks, underlying the Dolomitic conglomerate which has been deposited on its denuded edges, is a most important indication that the trough of coal-measures is to be found at a sufficient distance to the north-east of Brabourne to allow of the coming in of the carboniferous limestone and the millstone grits, which in Somerset and in Northern France underly the coal basin, somewhat as I have shown in the section. (Fig. 3 D.)

This boring has verified the exact position of the Pembroke-Mendip anticline, mapped in 1894,† that defines the southern range of the South Welsh and Somerset coalfields, as well as those of Northern France. In Somerset it emerges from beneath the Triassic, Liassic, and Oolitic rocks, and in Northern France it runs along the line from Marquise, past Ferques, to Fléchinelles and Douai, and beyond. In the district under consideration it runs from the north-west to the south-east, from Wye, at the foot of the Chalk Downs, to Folkestone, and passes under the straits to the south of Cape Gris Nez.

The south-eastern coalfield has its western boundary parallel to this line, at a sufficient distance to allow the carboniferous,

† Dawkins' "On the Probable Range of the Coal Measures in Southern England"—Trans. Fed. Inst. Mining Engineers, vi. p. 17.

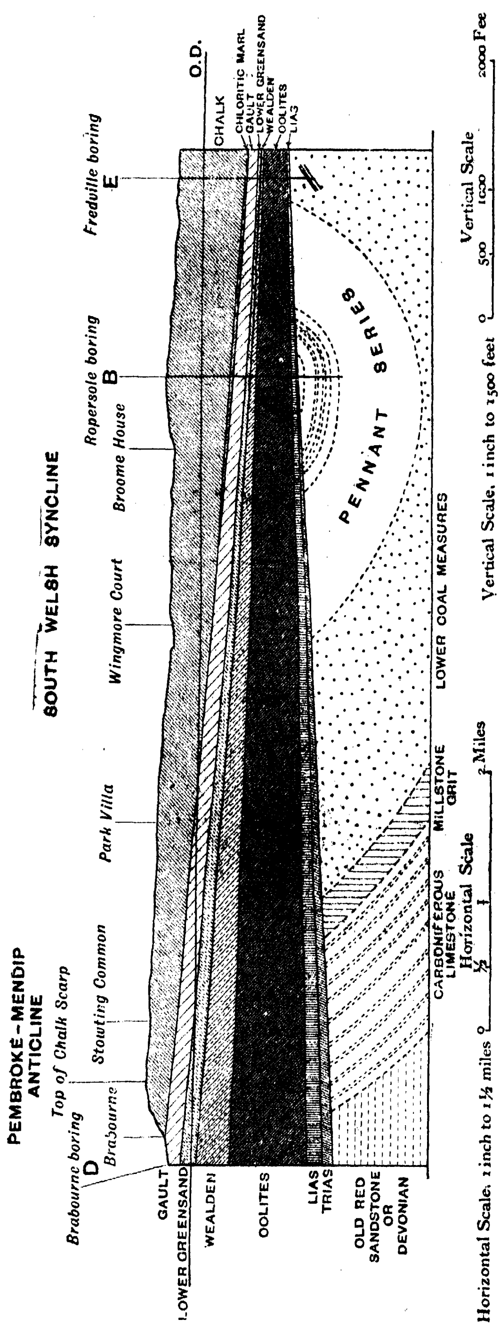

FIG. 3.—SECTION SHOWING PROBABLE ARRANGEMENT OF STRATA BETWEEN BRABOURNE, ROPERSOLE, AND FREDVILLE.

limestone, and millstone grit to intervene, with a high dip like that at Brabourne, as shown in Fig. 3, taken from Brabourne (D), to Ropersole (B), and Fredville (E).

If the relation of this section to that of Fig. 2 be noted on the map (Fig. 1), it will be seen that the sections are approximately at right angles, the one being taken along the dip, while the other runs along the strike of the coal measures. Their south-western boundary can, however, only be accurately marked by further borings, such as that at Ottinge, which I had to relinguish in 1899 in the Oolites at a depth of 842 feet, owing to the liquidation of the Kent Coal Exploration Company. It is approximately represented by the dotted line on the map (Fig. 1), running from the chalk cliffs north of Eastwear Bay, Folkestone, through Lyminge, and crossing the river Stour about half-way between Wye and Godmersham. From this line the south-eastern coalfield ranges eastwards, past Dover and Ropersole, over a very large distict in Kent, its northern marked approximately by the lined area on the map, Fig 1., and eastern boundaries being as yet unproved. It passes under the channel in the direction of Calais, where the coal-measures were struck in a deep boring in 1850.

The Further Extension of the South Coalfield.—These discoveries were laid before the Commission on Coal Supplies in 1903, and caused further experiments to be undertaken by the Kent Coal Concessions Company, organised by the energy of Mr. Arther Burr, and acting under my advice. In the borings described above, it had been proved that the strata between the Gault and the coal-measures thinned off, with great rapidity, to the north and east, as Godwin-Austen said they would thin off. Consequently my attention was directed to the northern and eastern borders of the proved portion of the coalfield. Sites for boring were selected, and the further explorations began in 1904, and are now being carried on, with the result that the only two borings which are as yet deep enough to strike the coal-measures, have resulted in the discovery of valuable seams of coal.

The Boring at Waldershare.—The first to be considered is that at Waldershare, about three miles due east of Ropersole (Fig. 1, E.) It began in the chalk, at 325 feet above O.D., and has now reached the depth of about 2,270 feet, or 1,955 feet below O.D. The section is as follows:—

Waldershare Boring.

	Depth. ft.	in.	Thickness. ft.	in.
Chalk and chloritic marl ..	820	0	820	0
Gault	976	0	156	0
Lower greensand	1,046	0	70	0
Purbeck-Wealden	1,088	0	42	0
Oolites	1,389	0	301	0

* For details as to the coal-measure shales, I am indebted to the late Sir Joseph Prestwich.

	Depth. ft.	in.		Thickness. ft.	in.
Lias	1,394	0	.	5	0
Coal-measures.—Thick coarse sandstones, with numerous pebbles of coal, sometimes forming a coal conglomerate, with subordinate layers of bind shale and underclays and occasional nodules of clay ironstone ..	1,743	0	..	349	0
Binds (claystones), shales, and underclays, with one thin layer of sandstone	1,816	11	..	73	11
First coal, blazing	1,818	7	..	1	8
Fire clay	1,825	3	..	6	8
Bind	1,878	0	..	52	9
Second coal, blazing	1,881	4	..	3	4
Fire clay	1,887	2	..	5	10
Bind	1,604	3	..	16	1
Third coal, blazing	1,908	9	..	4	6
Fire clay	1,911	0	..	2	3

Fourth coal, according to boring returns	1,956	8	..	1	4
Fine clay passing into bind.	1,961	10	..	5	2
Fine grey sandstones and binds in equal proportions ..	2,244	1	..	282	3

The boring is still going on.

The four coal seams and associated fire clays form a group of workable beds, the coals presenting a total thickness of 10 ft. 10 in.

By this discovery the range of the coalfield is extended about three miles to the east of Ropersole.

The Boring of Fredville.—The last boring to be considered is near Fredville-park, close to the railway, and about three miles to the north-west of Waldershare, and a little under two miles to the north-east of Ropersole. It was carried on in 1905-7, and presents the following section:—

Section of Fredville Boring.

	Depth. ft.	in.		Thickness. ft.	in.
Chalk and chloritic marl ..	860	0	..	860	0
Gault	948	0	..	148	0
Lower greensand	990	0	..	51	0
Purbeck-Wealden	1,035	0	..	36	0
Oolites	1,358	0	..	323	0
Lias	1,368	6	..	10	6
Coal-measures	—		..	—	
Shales and binds with one ten feet bed of sandstone ..	1,402	0	..	37	6
Bind	1,423	0	..	21	0
First coal, hard but blazing ..	1,424	6	..	1	6
Fire clay	1,427	6	..	3	0
Shale and bind	1,445	3	..	17	9
Second coal, hard, blazing ..	1,446	9	..	1	6
Fire clay	1,447	3	..	0	6
Shale	1,448	9	..	1	6
Bind	1,458	0	..	9	2
Grey sandy bind with subordinate layers of sandstone	1,499	0	..	41	0
Grey bind	1,501	5	..	2	5
Dark shale	1,501	6	..	0	1
Third seam, bituminous ..	1,510	10	..	4	4

The coal-measures up to the present time have only been penetrated to about 106 feet, and the boring is to be carried on to a depth of 2,500 feet from the surface, so as to ascertain the coal seams in a thickness of 1,000 feet of coal-measures. The three seams already proved are two of 1 ft. 6 in. and one of 4 ft. 4 in. all hard, bright-blazing coals. The dip of the beds is 17°.

The Sub-divisions of the South-Eastern Field.—We must now discuss the very difficult question as to whether the groups of seams in these four borings can be referred to distinct horizons. In my report to the Commission on Coal Supplies, I stated that the seams at Dover and Ropersole probably belong to the same series, although the several seams could not be identified, and that judged by the plants they belonged to the upper group. This conclusion has since been confirmed by the study of the physical character of the coal-measures in the coalfields of Bristol and South Wales, and more especially of the singular conglomerates, formed of coal pebbles, first noted by Logan and De la Beche. The thick coarse grey sandstones both of Dover and Ropersole are identical with those of the Pennant grit series, in which the coal seams are few in the south-western coalfields. The section at Waldershare probably shows the base of the Pennant sandstones, resting on the Lower Shales and Binds, the equivalents of the above south-western coalfields, so rich in coals. It is identical with the section in the Bristol coalfield given by Mr. Anstie, near Bitton. The coal-measures at Fredville also, in my opinion, belong to the same series. Whether the coals are the equivalent of those struck at Waldershare, or belong to a lower horizon in the Lower Shale Series, remains to be proved by the results of deeper boring.

As the evidence stands at present the seams proved in the south-eastern field are:—

	Seams.		Thick. ft.	ins.
Dover, in Pennant grit	13	..	22	6
Ropersole ,, ,, ... (thin)	12	..		
Waldershare, in Lower Shale Series ..	4	..	10	3
Fredville* ,, ,, ,, ,, ..	3	..	7	0

* These are figures corrected for the dip of the strata.

They occur in two, or perhaps three groups, and those in the Lower Shale Series are the most important.

The Structure of this portion of the Coal-field.—The dip of the strata throws light as to the structure of this portion of the coalfield. The high dip at Waldershare, on the east, of 30°, sinks to zero at Ropersole, a fact that can easily be explained on the hypothesis that it is the corresponding fold on the east to that so strongly marked at Brabourne on the west, as shown in the section, Fig. 3. The lower coal-measures would under these conditions crop out on the north-eastern side of the basin, in the two places where they have been looked for. In other words, the north-eastern side of the trough of coal-measures has been proved in this direction, although the exact margin has not been fixed. It has, however, been pushed two miles further to the north-east (see map, Fig. 1). The trough passes from Dover to the north-east, making for Canterbury, and is one of the series so valuable in Northern France and Belgium.

It is further to be noted that the average dip of the Lower Shale seams at Waldershare is 20°, or 10° less than that of the Pennant series above. At Fredville it is 17°. This may indicate an unconformity between the two groups of strata.

The South-Eastern Field Available.—I turn now to the question as to the availability of the coalfield. The denuded surface of the coal-measures occurs at Dover at 1,100 feet below O.D., at Ellinge at 1,206, at Ropersole at 1,100 feet, at Waldershare at 1,069, and Fredville at 1,109, is sufficiently near the surface to be worked. Coals are now being obtained from depths in Britain, amounting to nearly 4,000 feet. In Kent they are well within the above limit of depth laid down by the two last Royal Commissions on British Coalfields. The lined area in the map Fig 1, represents the approximate region in which the coal seams struck in the borings may be expected to occur in East Kent.

It will undoubtedly be extended over the adjacent districts by the borings now being made under my direction, by the Kent Coal Concessions Company, and by other similar enterprises. It will probably turn out to be a large, narrow trough, as in North France and Belgium, one of a series extending north-westwards from Dover under the newer rocks, linking the above coalfields with those of Somerset, to the north of the Pembroke-Mendip anticline, which represents in a restricted sense Godwin-Austen's axis. It is probably not less than 8,000 feet thick. It is proved by the few borings which have only penetrated it it for a short distance, to be of great value. It will probably rank, when fully developed, among the important coalfields, and cause centres of industries to be established in Kent, like those of Liège and Valenciennes. It will probably attract a large population to the lonely downs, that will by their labours add to the wealth of the nation, and at the same time convert the white into the "black country," or at all events into "studies in black and white."

Conclusion.

In the preceding pages we have traced the gradual verification of Godwin-Austen's theory by a series of experiments carried on during the last thirty years. It has ultimately added a new coalfield to the national assets. It is a striking instance of the value of scientific research to the nation.

DISCUSSION.

The Chairman, in opening the discussion, thought the author had put before the audience the hunt after coal on the south-eastern coalfield in a most fascinating manner. He remembered some years ago, in the course of one of the annual duels between Sir Edward Watkin and Mr. James Staats Forbes, Sir Edward being a firm believer in the existence of coal at Dover, and the Chatham Company being a little sceptical on the matter, that one of the audience at the meeting of the Railway Company who asked "what about coal?" received the reply, "I am told that coal has been found in the neighbourhood of Dover, and, if that is true, then we shall see what we shall see." He thought the author would agree with him that it was still necessary to use the same cautious phraseology. The Professor had undoubtedly brought certainty very much nearer than it was in those times, and, as he showed, depth was now no serious difficulty in mining. Personally he had had a good deal to do with another metal, and in all probability, if it had been steam coal instead of gold, it would have been quite as valuable, but there would not have been such a fuss made about it. The width and the value of the coal were the important points to be considered. If the widths of which the author spoke were of such a character as those who understood coal mining believed to be payable, he had very little doubt that, sooner or later, money would be forthcoming to make a thorough practical experiment of what the coal measures were capable of producing. In fact it might be said that a really practical experiment was already being made, because shafts were being put down at Waldershare and Fredville which, he believed, were of a size capable of being used for

hoists. With regard to the Professor's remarks on the question of the development of coalfields spoiling the beauties of the scenery, a good many of his friends had said to him that it would be a pity for Kent, the garden of England, to be spoiled by chimneys and smoke. If those people only knew the struggle that a good many landlords had gone through during the last twenty years to hang on to their estates by their eyelids, and at the same time do their duty by them, he did not think they would look at the matter quite in that light. If, as the Professor said, the coalfields would be a commercial advantage to England, he thought they would manage to put up with the scenery being occasionally interrupted by chimneys. A great friend of his, Lord Darnley, had a beautiful estate in the neighbourhood of Strood, and within a few miles of his park 30 or 40 chimneys could be counted giving forth large masses of smoke through the greater part of the day, but he had not observed that the neighbouring country or park had been in any way spoiled. He was sure that if eventually capitalists were willing to pnt up chimneys further east in Kent, the inhabitants of the county would put up with that inconvenience. That, perhaps, was rather a far cry yet, but he hoped in two or three years time, if the author was willing to give another paper upon the subject, he would be able to confirm his prophecies and conjectures by a very practical description of what capitalists believed the coalfields could produce. He was sure all present would agree that the hunt after coal described by the Professor had been of a most fascinating description, based upon a conjecture which only had for its proof geological surmises. Now the results of those conjectures and surmises were known, all would agree with the author that science had been amply borne out in the present instance by results, and it would give people greater confidence in trusting in those scientific forecasts which geologists and mining engineers had to make. He had a good deal to do with mining engineers and geologists, and he knew they were most cautious in using any expression which gave a distinct idea as to value; but Professor Boyd Dawkins had deliberately stated that the coal measures in Kent were valuable. When a man of the author's distinction and reputation deliberately used an expression of the kind, it was pretty certain that sooner or later--he hoped sooner—it would be found that the expression was justified.

Mr. W. WHITAKER, F.R.S., pointed out that, curiously enough, the two borings which were of the greatest interest were those which had not given economical results, viz., those at Brabourne and near Battle. Of all the Kentish borings, the one at Brabourne was the most interesting as proving a distinct negative, and that the edge of the rocks had been reached which underlaid the coal in other parts. It was interesting to notice that, where coal measures were touched, their depth did not vary very much. In some cases it did apparently, but it must be remembered that some of the borings started on high ground compared with the lower ground at Dover. If the levels were all reduced to Ordnance datum, it would be found that the depth of the coal measures came in all cases within a few hundred feet. The same feature had been found in the borings which had been made near London. At a depth of something like 1,100 feet below sea level, old rock was found, and in London most of it presumably was older than carboniferous. The borings under London for coal had not been thrown away, because they pointed to the fact that, at present, it was impossible to get coal under London, so that the beauty of London would not be spoiled! He did not think much of the smoke bogey which had been raised in connection with coalfields, because collieries were not worked on the principle of erecting as many chimneys and making as much smoke as possible. Kent had suffered more from its cement works than it was likely to do from collieries. When looking at some Kent cement works many years ago, he remembered counting a number of chimneys, which were all emitting a nasty, white acrid smoke, much worse than the smoke produced from the combustion of coal. Modern collieries also used underground electric haulage, and that system would probably be used in the Kent collieries when they were fully developed. Undoubtedly, however, there would be a certain amount of smoke and destruction of scenery; but it was pleasant to reflect that the descendants of the people who were living at the present day would find, when the coalfields were worked out, that the country had reverted to its natural beauty. Nature had an uncommonly good way of beautifying refuse heaps and spoil banks. He had walked over ground where collieries had existed many years ago, and he should never have guessed it; everything had gone back to the green and ordinary look of the country. It was necessary in considering the question to take a view a little outside the mere garden view. Kent might be the garden of England, but this country did not exist for purely gardening purposes. If a coalfield could be worked at a profit over a large area of Eastern Kent, was it reasonable to expect people to think of the mere beauties of scenery compared with the wealth, strength, and power it would give to England at large? It was by its coalfields that England was powerful, and the addition of a coalfield to this country was distinctly a patriotic work.

Mr. GEORGE HOLLINGWORTH thought that, from the point of view of the depth at which coal had been discovered, there was nothing to prevent the establishment of collieries in Kent, while several of the seams which had been proved were of a workable thickness or width. The question of thickness resolved itself into the question of the price obtained for the coal. A

particular seam might be considered as thin, compared with seams in a large coal district where the seams were thick and the price was in consequence low; but the same thickness of seam in a place where coal was high became workable. One point which had not been much touched upon in the paper was the character of the cover of secondary rocks as bearing upon their availability. So far as he understood the question of the difficulties of sinking through the upper rocks in Kent, they were very much less than in many places in this country. The probability was that there would not be any very great quantity of water to contend with, which was one of the most serious difficulties in coal-mining. He knew of collieries where as much as six million gallons of water per day had to be dealt with, but that quantity was not likely to be in any way approached in Kent. The Chairman had stated that sinkings were in progress of sufficient size to deal with large outputs. The sinkings were only in the early stage of construction, the deepest at present being a little over 400 ft., while the nearest seam to the surface was about 1,500 ft. He anticipated that, in the course of a year or two, more than one pit would have been sunk down to the coal measures, and this would dispose of any question there might be as to whether the Kent coalfields were commercially workable or not. In his opinion that was already a a foregone conclusion, but it would be possible to demonstrate it by actual fact before long.

Mr. D. A. LOUIS thought it might be of interest if he stated that he had recently visited the Kent coalfields, and inspected the cores, and he had been particularly struck with their similarity at different parts of the field. In one place a boring of 1½ ft. diameter was being made, while at another the boring was of a very considerable magnitude, namely, 21 in., and the man in charge of the work went down the hole to show him that it was of a really workable size. Two syndicates, which had very considerable confidence in the predictions of the author, were undertaking the work, one of them conducting the borings and the other the sinkings, and very serious work was being done, all the timber being ready for the erection of a considerable head, and foundations were being put in for big engines. He should like to ask the author how the dips were ascertained.

Captain ARTHUR H. LIMPUS, R.N., stated that he recently read in one of the mining journals a paper by Professor Lapworth, who described how he was apparently learning to define the boundaries of the great Midland coalfield, which he referred to as underlying the red Triassic rock, and he also referred to the various thicknesses of the covering rock. He would like to ask Professor Boyd Dawkins whether the same layer of Triassic rock and the same coal measures were found in the midland and northern coalfields as in the south. It would also be of interest to know whether steam coal was found in the same boring as ordinary house coal or cannel coal.

Professor BOYD DAWKINS, in reply, stated that he ascertained the dips in the only possible way open to him, namely, by taking the measurements of the dips in all the cores that he could obtain and averaging them. In that way he worked out the very curious fact that, in the Pennant series, the dips were higher than in the lower shales, which occurred at Waldershare below the Pennant series. He did not know that there was any other way of ascertaining the dips. He knew it was not possible, on such a small horizontal space as was offered by a core, to get absolute accuracy, but he did his best and averaged a very large number, and he did not know how he could have formed any idea of the dips in any other way. Professor Lapworth, in his excellent account of the Midland coalfield, dealt with the thick deposit of red rock which overlay it. Godwin-Austen had pointed out that, in all probability, there would be no Trias in the south-easterly regions of Kent and Sussex. The only trace obtained of it was at Brabourne, which was outside the coalfield, and there Triassic rocks, which were the pebble beaches belonging to the great sand banks which, in the Midland and North of England formed the red sandstone which overlies the coal measures, were obtained. With regard to the question of whether steam coal was found in the same mine as house coal, it was a fact that, in some instances in South Wales and in the Forest of Dean, a seam of coal started by being of the ordinary bright blazing character; then it would lose its bituminous or volatile element and be converted into steam coal, with a higher percentage of carbon; and then the last stage in the change of the physical character of the coal was found in the steam coal being replaced again by anthracite. So far as he knew, no anthracite had been found in the Somerset fields, and he was not sure whether any steam coal, as obtained in South Wales and as used for naval purposes, had been found there. A good deal of confusion existed with regard to the designation of steam coal. The steam coal of Midland and Northern England was different from the best steam qualities of South Wales coal. He used the term steam coal as referring to coal of higher qualities, with a greater percentage of carbon, as found in South Wales. He did not know that any such coal had been found in Somersetshire, and he did not at all anticipate that any of this higher class of steam coals would be found in the Kent area, for the very simple reason that they were not found on the Continent, in Northern France, Belgium, or in Germany.

On the motion of the CHAIRMAN, a hearty vote of thanks was accorded to Professor Boyd Dawkins, for his exceedingly interesting paper, and the meeting terminated.

NOTES ON INDIAN RAILWAY SYSTEMS.*

I.

The East Indian Railway.—In examining a few typical systems, the East Indian Railway claims early attention, as second in point of aggregate mileage, and second in age—for a section of the line, 38 miles in length, was opened for traffic in 1854. The East Indian Railway proper has a length of 1,932.87 miles, and with its three subsidiary systems has an aggregate length of 2,196.22 miles of 5 ft. 6 in. gauge. The construction of the main line, from Calcutta to Delhi, was completed in 1867. Double-headed steel rails weighing 75 lbs. per yard, and bull-headed steel rails weighing 85 lbs. per yard are used on the main line, but instructions have been issued that the heavier rails are to be used on all main-line renewals. For sleepers, cast iron, various Indian woods, and Australian hard woods have been miscellaneously employed. Cast-iron plate sleepers are to be used with all new 85 lbs. rails. Stone ballast is used throughout. No specially difficult features were encountered in the construction of this line, the gradients being easy, the ruling gradient on the main line being 1 in 300, with one case of 1 in 200 and one of 1 in 100. The worst gradient on a branch line is 1 in 80. The sharpest curve has a radius of 1,525 feet.

The lines were purchased from the East Indian Guaranteed Railway Company by the State in 1880. The purchase price was £32,750,000 sterling, of which four-fifths was paid in the shape of a terminable annuity, while one-fifth of the annuity was deferred, and holders of this portion, representing a working capital of £6,550,000, constitute the present East Indian Railway. The holders of this stock receive a guaranteed rate of interest of 4 per cent. plus a share of the surplus profits until 1919, when the balance of the annuity will become payable up to termination in 1953.

The rolling stock used on this line included (at the end of 1904) 144 passenger engines and 755 engines used for goods and mixed traffic. The average mileage run per passenger engine is 34,543; the goods engines have a smaller annual mileage of 20,897 miles. Per diem the respective mileages are 94 and 57. The ton-mileage hauled per engine is 8,652,000 miles. The coaching stock amounted to 2,380 vehicles, which covered an average mileage of 142 miles each per day. The goods vehicles numbered 17,382 of all classes, and covered an average distance of 50 miles each per day. The profit per goods-vehicle mile was just over 19 pies (about 1·68 pence).

The Great Indian Peninsular Railway.—The Great Indian Peninsula Railway can boast of having had a section open for traffic in 1853, and possesses a greater mileage than the East Indian Railway. The Great Indian Peninsular Railway proper covers a distance of 156·63 miles of 5 ft. 6 in. gauge, while subsidiary lines, also of broad gauge, cover 1,240·53 miles. There is also the Gwalior Light Railway, 183·53 miles in length, of 2 ft. in gauge. Bull-headed steel rails, weighing 82 and 86 lbs. per yard, have latterly replaced the earlier double-headed iron rails, and similarly cast-iron pot sleepers are replacing the wooden sleepers which were first employed. The type of ballast used varies with the locality—broken stone, gravel, and sand being variously used. The ruling gradients on ordinary sections of the line, vary from 1 in 100 to 1 in 200, except on the Ghat section, where 1 in 37 is to be found. The line was purchased from the Great Indian Peninsular Guaranteed Railway Company by the State in 1900; the purchase price was £40,781,568 payable up to the 17th August, 1948, in the form of a terminable annuity of £1,268,516. Previously the State had guaranteed interest, and in carrying out this guarantee, fairly heavy losses were sustained between 1890 and 1900. These have since been greatly reduced, but have not yet given place to a profit. The rolling stock used comprised, at the end of 1904, 821 locomotives, no differentiation being made between those used for the passenger and for the goods and mixed services. The respective engine mileages for the two classes of service have, however, been computated; passenger engines covering 25,619 miles per annum (or 70 per day), and goods engines 18,692 miles per annum (or 57 per day). The ton mileage hauled per engine per annum was 6,207,000. The passenger vehicles numbered 2,243, and covered an average distance of 130 miles per diem. The goods vehicles of all classes numbered 11,552, and covered an average distance of 38 miles per day. The average profit per goods-vehicle miles was 20·8 pies (about 1·73 pence).

The Eastern Bengal State Railway.—The association of this State-operated broad gauge system and the Government began at an early date in 1868, when the State acquired the section between Calcutta and Port Canning. Further acquisitions took place in 1884 and 1887, when a number of broad gauge lines were acquired and merged into the Eastern Bengal System. At that time the mileage of 5 ft. 6 in. track open for traffic was 235 miles, a length increased to 279 miles in 1904, while 106 miles are either under construction or sanctioned. This system also comprises 638 miles of metre gauge track, the construction of which was commenced in 1874, and two short lengths of 2 ft. 6 in. gauge, covering some 67 miles. Other short lengths of 2 ft. 6 in. gauge have been converted into metre gauge lines.

The permanent way on part of the broad gauge lines is now being relaid with 85 lb. bull-headed steel rails in place of 73 lb. and 75 lb. double-headed steel rails. For sleepers, cast-iron and sal wood are used, being laid on brick ballast, except where stone ballast is being used in relaying the track with 85 lb. rails.

On the metre gauge sections, flat-footed steel rails weighing 50 and 41¼ lbs. per yard, laid on sal

* Abstracted from the Indian Government Railway Returns.

sleepers, are employed. Brick ballast is being replaced with stone and shingle. In neither case are the gradients heavy, the ruling broad gauge gradient being 1 in 300, and the ruling narrow gauge gradient, 1 in 200. Financially regarded the system as a whole has been exceedingly profitable, substantial gains having accrued to the State during the past 16 years. Contrasting the gross earnings per mile per week on the three gauges during the past three years, the following striking figures are obtained :—

	1902.	1903.	1904.
	Rupees per week.		
Broad gauge	728	707	751
Metre gauge (excluding Dacca section)	235	239	233
Narrow (2 ft. 6 in. gauge)	66	72	82

The relation of working expenses to gross earnings during these three years has been increased 48·18 to 53·14 per cent. on the broad gauge, from 48·65 to 55·69 per cent. on the metre gauge, and has been reduced from 78·03 to the more commercial ratio of 60·86 on the narrow gauge.

The locomotive rolling-stock used on the 5 ft. 6 in. gauge, consisted of 59 passenger and 88 goods and mixed traffic engines. The annual passenger engine mileage was 22,212 (or 61 miles per diem), and the annual goods engine mileage was 21,380 (or 59 miles per diem). The ton-mileage hauled per engine per annum was 5,141,000 tons. The passenger vehicles numbered 589 and covered 79 miles per day. The goods vehicles of all classes amounted to 3,340, the average mileage per vehicle per day being 25 miles. The average profit per goods-vehicle mile during 1904 was 17·28 pies (or 1·44 pence).

The North Western (State) Railway System.—The extensive system which has a length of nearly 4,000 miles, is almost entirely laid on the 5 ft. 5 in. gauge. The actual length of broad gauge line open for traffic is 3,812-59 miles. There are no branches or sections of metre gauge, but some feeder lines of 2 ft. 6 in. (95·98 miles) and of 2 ft. ·02 in. (6·18 miles) are in use. One particular feature of the system is its extreme length. For 23 years there has been a continuous chain of railway communication on this system from Calcutta to Peshawur, a distance of 1,555 miles. As one Imperial system, the North Western has only existed under that name since 1886, when a large number of separate systems were amalgamated under one name and one control.

Of the engineering features of the line, it can only be said that the permanent way is of various types, and that the curator of a museum of rails would find an interesting variety of specimens of iron and steel rails, flat-footed, double-headed, bull-headed, the weights also varying between 60 and 100 lbs. per yard. For sleepers, wood, cast-iron pots, and steel transverse sleepers are all used.

The reasons for the construction of one section may be mentioned before passing on to a consideration of revenue or equipment. On the right bank of the Indus a chord was constructed between Kotri and Rohri (about 190 miles in length) on account of the set of the River Indus, which rendered the line along the right bank dangerous. Frequent breaches caused communication with Karachi to be intermittent, dislocating the export trade, and cutting off communication with the North-West Frontier Province. The present line, constructed on the left branch of the river, is on high ground, and less liable to inundation. It saves 36½ miles on the through distance from the Punjab to Karachi, and also gives an alternative route to Quetta.

On the financial side, 1904 proved to be a record year. The nett earnings amounted 5·92 per cent. on the capital outlay, the nett gain to the State was £464,520 sterling; the expenditure was 47·60 per cent. of the earning; while the revenue per line of mile per week was 361 rupees.

The locomotive equipment comprises 719 engines, no differentiation being made between passenger and other locomotives. The average mile per locomotive (of all classes) per day is 27,124; and the annual ton mileage hauled per locomotive is 8,373,000 tons. The passenger rolling stock amounts to 2,369 vehicles of all types, these covering an annual average mileage of 47,667 miles apiece, and an average daily mileage of 131 miles. The goods vehicles number 11,566, these having an average annual mileage of 63 miles. The average profit per goods-vehicle mile in 1904 was 17·36 pies (or 1·45 pence).

(*To be continued.*)

TRADE WITH TUNIS.

In his report on trade with Tunis (Cd. 3283), Mr. Consul-General Berkeley shows how it is that French trade in cloths is increasing rapidly in Tunis at the expense of British. Fifteen years ago France did but little trade with Tunis in any cotton goods; now, whilst the United Kingdom maintains a considerable superiority in bleached and unbleached cloths, it only just holds it own in printed cloths, and falls behind very considerably in dyed cloths and manufactured articles. It will not be forgotten that British cotton fabrics pay a duty of 5 per cent., while those of French manufacture enter free. This duty does not seem to affect the British trade in unbleached tissues, but it tells on that in bleached and other goods, and this disadvantage is increased by the French practice of direct sales between the manufacturer and the local dealer to the exlusion of the export agent, who seems to be an unavoidable adjunct to British trade in Tunis. The latter has thus not only to contend against the original disadvantage of the 5 per cent. duty, but against a further charge of 7 to 10 per cent., which represents a profit without which the export agent will not risk dealing on credit abroad. Admittedly British cotton fabrics sold in Tunis are superior to the French, especially those intended for native use, but it is a great deal to expect that they should continue to hold their own under a penalty of 12 to 15 per cent.

HOME INDUSTRIES.

Export of Cotton Goods.—The figures relating to the production of raw cotton, and the export trade in cotton goods, afford an interesting comparison between the United Kingdom and the United States. Notwithstanding the efforts of other countries, the United States still supply three-fourths of the raw material used by the outside world in the manufacture of cotton goods, and the United Kingdom is almost as dependent upon the United States to-day for its supply of raw cotton as it was in the sixties, when the American Civil War cut off American supplies. But whilst the United States supply the raw material, it is the United Kingdom which, in special degree, creates and distributes the finished product. *Bradstreet* gives the values of the exports from the two countries during 1905 and 1906:—

	1905. dols.		1906. dols.
Cotton cloths:			
United Kingdom..	344,630,000	..	366,908,200
United States .. .	47,652,434	..	32,282,504
All other goods:			
United Kingdom..	103,117,500	..	117,815,700
United States	8,808,566	..	10,678,544
Total all cotton goods:			
United Kingdom..	447,748,400	..	484,723,900
United States	56,461,000	..	42,961,048

These figures show that the United States do not export one-tenth part of the cotton goods exported by England, and yet the former country grows three parts of the world's supply of cotton, whereas the United Kingdom does not raise a pound of cotton, and has to import its entire supply of raw material. Small as was the American export in 1905, it was much smaller in 1906, whilst the exports of the United Kingdom showed large expansion. The explanation of the decrease in American exports is to be found in the practical cutting in two of the American export trade in cotton cloth with China. Great Britain also shipped less to China in 1906 than in 1905, but then China takes only about 10 per cent. of all British exports, whereas she takes more than half the American exports, so that the effect of the shrinkage upon American trade was much more significant than upon British. There has, of course, been great expansion in the American domestic trade.

The Motor Omnibus.—The publication of accounts and statements of the various omnibus companies catering for the transport of the metropolitan public demonstrates the peculiar conditions under which this industry is being carried on, and the great risks accepted by shareholders in the motor omnibus companies. These companies have practically destroyed the horse omnibus companies as such, they have seriously affected the earnings of "the Tubes"; they are carrying as many passengers as the most sanguine anticipated, and yet there is good reason to believe that, if proper allowances were made for depreciation, not one of them could be shown to be running at a profit. Admittedly most of them are being worked at a loss. In the desire to steal a march upon the horse omnibus companies, they have spent immense sums in putting upon the streets vehicles insufficiently tested, both from the point of view of official requirements, and earning power. In their report the directors of the London Road Car Company, for example, tell their shareholders that early in October last a large number of horse cars were withdrawn, but the directors "extremely regret to have to report that when the motors to replace these horse cars were presented to the police authorities for licensing they were most unexpectedly rejected, on the alleged ground of not being fit for public use." Again, the chairman of the Associated Omnibus Company, told the shareholders in general meeting that motor omnibuses had been placed on the streets without regard to their efficency or suitability. If there had been less haste much money would have been saved. "As it is," he added, "there are some hundreds of motor chassis in London absolutely useless. Some have broken down, others will not work properly, and others the police will not pass as they do not comply with the police regulations." Whilst injuring other forms of transport the motor omnibus is spelling heavy loss to its owners. The pioneer has suffered, as the pioneer always suffers. Of course the present vehicle will be improved. It is too heavy and costly to work. Lightened and cheapened it will leave no place for the horse omnibus, but not a few will suffer heavily in the process.

The Horse Omnibus Reports.—Meantime the half-yearly reports issued by the horse omnibus companies, which until recently controlled the street traffic, show the effect of the competition upon their profits. Glancing at the figures submitted by the oldest and largest of the horse omnibus companies, it is noticeable that it carried more passengers in the second half of 1906 than in the corresponding period of 1905, but its net working profit fell from £19,100 to £1,430. In the second six months of 1905 it carried 108,068,400 passengers, as against 108,655,300 in the corresponding period of 1906, but the gross receipts fell from £618,790 to £613,100, whilst the dividend has fallen from 6 per cent to 5 per cent, and the reserve from £145,000 to £130,000. The depreciation in capital value of the company's stocks has been, as was to be expected, very serious. As was pointed out in these Notes a year ago the directors have been in a most difficult position. They had no wish to "rush" the change from horse to motor traction, but with other companies springing up on all sides to compete for the traffic, and the public determined to have motor carriages, they had to adopt the motor omnibus before they were satisfied that they had found the right type of vehicle.

Steamship Developments.—Important developments in steamship services may be noted. In the Newfoundland House of Assembly a scheme is under

discussion for a weekly service of 17-knot steamers between Killery, on the west coast of Ireland, and Green Bay on the east coast of Newfoundland. This scheme is said to ensure a saving of thirty-two hours over any other Atlantic route, and the Colony is said to be willing to pay an annual subsidy of $75,000. Some time ago the Commonwealth Government made a new contract with an English syndicate to take up the Australasian mail service, and the cost of the new fleet is estimated to be between three and four millions. Financial discussions, however, have delayed the completion of capital arrangements, and the fear has been expressed in Australasia that the service will not be ready to time. Again, at a meeting of shipowners, manufacturers and others, held at Buenos Ayres a few days ago, it was decided to create an Argentine Transatlantic Steamship Company, and a committee has been appointed to put the project into execution. Then the United States have in contemplation a line of 16-knot steamships from United States ports to the Gulf of Mexico and Brazilian ports. These various enterprises, should they, or any of them, be carried out, can hardly fail to bring work to British shipyards.

Mineral Production.—The Home Office has just issued its preliminary returns of the mineral production of the United Kingdom for 1906. These figures show that the production of coal was considerably larger than in 1905, the output being 251,050,809 tons as against 236,111,150 tons in 1905. Ironstone also shows considerable increase as from 7,860,969 tons to 8,209,880 tons, and oil shale from 2,496,567 tons to 2,546,113 tons. Fireclay, too, showed increase from 2,847,122 tons, to 2,971,173 tons; clay and shale other than fireclay and oil shale falling from 306,561 tons to 252,275 tons. The number of persons employed underground increased from 691,112 to 709,545, and above ground from 167,261 to 172,800, a total increase of 23,972 persons, attributable for the most part to the increased production of coal, amounting to 15,000,000 tons more than in 1905; the increase in the exports of coal being 8,433,000 tons, or 17·7 per cent., the increase in the home consumption being 6,817,000 tons, or 3·6 per cent.

The Railway Position.—There would seem to be ground for the belief that 1907 will be a more favourable year for the holders of railway stocks, which are less in favour than they were some years ago. A succession of lean years, from the dividend point of view, has resulted in a serious fall in the prices of these stocks. In the decade 1863-1905 there was an increase of no less than £212,000,000, or 22 per cent. in capital expenditure, whereas the increase in net earnings was only 14 per cent. The return upon new capital is much less immediate and large in the United Kingdom than in new countries such as the United States and Canada. Here the increase in traffic is only about 3 per cent., there 10 per cent., and in Canada more, so that longer time has to elapse in the United Kingdom before new capital outlay becomes productive. But for some time to come there will be little occasion to spend much new capital on English lines. The expenditure of the last ten or twelve years will be bearing fruit in increased degree, and the further increase in capital charges should be comparatively small. Then railway companies have effected considerable economies in working, and further economies may be confidently anticipated. The railways are feeling the improvement in trade. Compared with two years ago there is an improvement of over 5 per cent., and in the eight weeks of the current year there has been a further improvement of nearly £300,000 as compared with the corresponding weeks of last year. It is true that coal and wages are disturbing features in the present position, but the present growth of the demand for coal is evidence of the activity of trade, which must benefit the railways; and if the demands of the men for higher wages are conceded it may be hoped, and even expected that, at any rate in many cases, more and better work will be given in return. On the other hand prices of railway stocks are at an unusually low level.

Shop Companies.—Nearly all the great shop businesses, those especially in London, are now run by limited companies. The individual shopkeeper is giving place to the joint stock company, and the tendency is towards amalgamation. Several of the leading industrial companies have now published the results of their operations for 1906, and *The Economist* summarizes the results in a series of useful tables. Speaking generally, last year was a very favourable period for the big shops of London. Taking the large and representative companies, the figures show an aggregate profit for the twelve months of £732,628, which compares with £686,835 in 1905, thus showing an increase of £45,793, or 6·7 per cent. Only two companies earned less than in the previous year, and in neither case was the shrinkage sufficient to affect dividends. At present prices the yields of the shares of these companies look tempting, ranging as they do from 4⅝ to 8 per cent., but the way in which the balance-sheets generally are drawn up leaves a good deal to be desired. The good-will is not stated separately, and, as a rule, though most of the ten companies set out substantial sums as reserve funds, they are not represented by separate investments.

CORRESPONDENCE.

Law Society's Hall,
Chancery Lane, London, W.C.
14th February, 1907.

Dear Sir,

It may interest you to know that a year ago, after the issue of the new e i on of the Report of the Committee of the Society of Arts on Leather

for Bookbinding, I caused the bookbinder who binds and repairs for this Library to obtain from his manufacturers a guarantee that all skins supplied to him are "sumach tanned and dyed and finished in same style as those which Dr. Gordon Parker analysed and of which we sent you a report."

The report referred to, of which I have a copy, was made in June, 1903, and states that three samples of leather submitted to Dr. Gordon Parker (being respectively brown, blue and red skins) "are all first-class moroccos . . . . free from any trace of mineral acids . . . . eminently suited for bookbinding purposes."

The leathers now used in this Library are: *Pigskin*, half binding with buckram, for heavy volumes; *Morocco*, half binding, for legal text-books and works of reference in constant use; *Coloured Calf*, whole and half bindings, for sets of law reports, law magazines, and other serials.

For old editions of text-books, kept only for reference and very seldom looked at, I am now using "art linen," which is strongly recommended by the binder and looks neat. I cannot yet say whether it lasts well.

"Law calf" was formerly much used here, but it was abandoned about 20 years ago, and its place has been taken, with satisfactory results, by the "coloured calf."

The rooms are now heated with hot-water pipes, as well as with open fire places. The electric light only is used.

Yours faithfully,
WALLER M. SINCLAIR,
Librarian.

Sir Henry Trueman Wood, M.A.,
The Secretary
The Society of Arts,
John-street, Adelphi, W.C.

GENERAL NOTES.

THE SOUTH AFRICAN PRODUCTS EXHIBITION.—This Exhibition is interesting not only from the character of its exhibits, but as showing that notwithstanding sharp differences the South African Colonies are prepared to act together upon occasion. The Cape Colony, Natal, the Transvaal, the Orange River Colony, and Rhodesia have combined to make the Exhibition a success, and to bring before the people of this country the products of South Africa. Perhaps the most important exhibit is that of cotton, grown on the eastern slopes of the Drakensberg. A ton and a-half of it has come over, only samples having reached England before, and its quality warrants the hope that by-and-bye South Africa will supply a substantial portion of Lancashire requirements. Another interesting exhibit is that of Cape wines. Of late years the trade in these wines with this country has been insignificant, why, it is perhaps difficult to explain. They were known many years before the Australian product found a market here, and it is claimed for them that, being less heavy, they should find a readier sale. However that may be, the present exhibition, as displayed by that veteran grower, Mr. Sedgwick, should do something towards quickening inquiry. Cape Colony makes a feature of the ostrich-feather farming, and there is a very attractive group of stuffed birds, the male, female, and their young. There are also fine specimens of the feathers. An important section of the Exhibition is that of fruits. The apricots are specially noticeable, some being from the Rhodes fruit farms, semi-dried as in California. Perhaps the least successful fruit exhibit is the pine apples from Natal. They are small and withered looking, and the mangoes, exhibited by the same colony, are not very attractive, being too green. The wonderful mineral wealth of the Transvaal is given a prominent place in the Exhibition, and the coal section is especially noticeable. The exhibits of tea are interesting. First grown at Kearsney, near the Zulu border, it is now being planted over a large area up to an altitude of 1,000 feet. There is already a considerable export trade which bids fair to grow rapidly. The Orange River Colony exhibits are mostly confined to cereals and dairy produce. Wool, of course, occupies a prominent position in the Exhibition, and the exhibits at the stall of the Women's South African Industrial Union deserve notice. So, too, the tobacco exhibits of Rhodesia. Altogether, the Exhibition is a very interesting one, and it is pleasant to note how Dutch and English have combined to make it a success.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday Evenings, at 8 o'clock:—

MARCH 13.—"Mediæval Stained Glass, its Production and Decay." By NOEL HEATON, B.Sc. LEWIS FOREMAN DAY, F.S.A., Vice-President of the Society, will preside.

MARCH 20.—"Smoke Prevention in Factories and Electric Supply Stations." By JOHN B. C. KERSHAW, F.I.C. SIR JOSEPH W. SWAN, M.A., F.R.S., will preside.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

MARCH 14.—"The City of Madras." By SIR JAMES THOMSON, K.C.S.I., M.A., late Member of Council, Madras. The LORD AMPTHILL, G.C.S.I., G.C.I.E., will preside.

MAY 2.—"The Applicability to Indian Rivers of the Italian System of Dealing with Silt." By SIR EDWARD CHARLES BUCK, K.C.S.I., LL.D., late Secretary to the Government of India, Revenue and Agricultural Department.

MAY 30.—"Irrigation Colonies in India." By LAURENCE ROBERTSON, I.C.S., Under Secretary to the Government of India, Revenue Department.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock :—

April 23.—"The Mineral and other Resources of Western Australia." By the HON. C. H. RASON, Agent-General for Western Australia.

APPLIED ART SECTION.

Tuesday evenings, at 8 o'clock :—

MARCH 19.—"Oils, Varnishes and Mediums used in the Painting of Pictures." By A. P. LAURIE, M.A., Principal of the Heriot-Watt College, Edinburgh.

APRIL 16.—"Joinery and Furniture Making." By A. ROMNEY GREEN. HALSEY RICARDO will preside.

APRIL 30.—"Lustre Pottery." By WILLIAM BURTON.

MAY 28.—"Sheffield Plate and Electro-plate." By SHERARD COWPER-COLES.

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

F. HAMILTON JACKSON, "Romanesque Ornament." Three Lectures.

LECTURE III.—MARCH 11.—Anglian carvings, — The Lindisfarne gospels — Italian workmen and influence in Northumbria—Anglian ornament based on classical data — Later Comacines, called Lombards, and their activity—Italians in Germany and Byzantine influence on the Rhine—The goldsmiths of the Lower Rhine and the Meuse — Byzantine underlying forms and germs of 12th century patterns —English MSS. of the 10th and 11th century—Details which appear in later ornament—Reciprocal influence of England and Germany, and early influence of England upon France—English and Scots missionaries—The cloister the cradle of Romanesque — English and other ecclesiastical craftsmen, and work done by them—Summing up.

PROF. HERBERT JACKSON, F.I.C., F.C.S, "Detergents and Bleaching Agents used in Laundry Work." Three Lectures.

April 15, 22, 29.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 11...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. F. Hamilton Jackson, "Romanesque Ornament." (Lecture III.)

Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. (Graduates' Section.) Mr. Harold Broughton, "Notes on the Design and Equipment of Electric Travelling Cranes."

Geographical, University of London, Burlington-gardens, W., 8½ p.m. Mr. Mark Sykes, "Journeys in Turkey and Asia."

Medical, 11, Chandos-street, W., 8½ p.m.

TUESDAY, MARCH 12...Hellenic Studies, in the Rooms of the Society of Antiquaries, Burlington-house, Piccadilly, W., 5 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Professor W. Stirling, "The Visual Apparatus of Man and Animals." (Lecture V.)

Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Mr. A. P. Trotter's paper, "The Construction of Overhead Electric Transmission-Lines."

Anthropological, 3, Hanover-square, W., 8½ p.m.

Colonial Institute, Whitehall Rooms, Whitehall-place, S.W., 8 p.m. Hon. C. H. Rason, "Western Australia and its Resources."

Pharmaceutical, 17, Bloomsbury-square, W.C., 8 p.m.

WEDNESDAY, MARCH 13...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Noel Heaton, "Mediæval Stained Glass, its Production and Decay."

Biblical Archæology, 37, Great Russell-street, W.C., 4½ p.m.

Geological, Burlington-house, W., 8 p.m. 1. Prof. Sidney Hugh Reynolds, "A Silurian Inlier in the Eastern Mendips." 2. James Archibald Douglas, "Changes of Physical Constants which take place in certain Minerals and Igneous Rocks, on the Passage from the Crystalline to the Glassy State; with a short Note on Eutectic Mixtures."

Japan Society, 20, Hanover-square, W., 8½ p.m. Mr. J. C. Hall, "Early Feudal Law in Japan."

Royal Literary Fund, 7, Adelphi-terrace, W.C., 3½ p.m. Annual Meeting.

THURSDAY, MARCH 14...SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Indian Section.) Sir James Thomson, "The City of Madras."

Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Dr. C. W. Saleeby, "Biology and Progress." (Lecture I.)

Mathematical, 22, Albemarle-street, W., 5½ p.m.

FRIDAY, MARCH 15...Royal Institution, Albemarle-street, W., 9 p.m. Prof. G. Lunge, "Problems of Applied Chemistry."

North-East Coast Institute of Engineers and Shipbuilders, Westgate-road, Newcastle-on-Tyne, 7½ p.m. Mr. R. J. Walker, "The Development of the Turbine."

Art Workers' Guild, Clifford's-inn-hall, Fleet-street, E.C., 8 p.m. Paper on "The Reciprocal Influence of Eastern and Western Art."

Quekett Microscopical Club, 20, Hanover-square, W., 8 p.m.

Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. Mr. W. Worby Beaumont, "Petrol Motor Omnibuses."

SATURDAY, MARCH 16...Royal Institution, Albemarle-street, W., 3 p.m. Prof. J. J. Thomson, "Röntgen, Cathode, and Positive Rays." (Lecture V.)

Journal of the Society of Arts.

No. 2,834. VOL. LV.

FRIDAY, MARCH 15, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

TUESDAY, MARCH 19, 8 p.m. (Applied Art Section.) Dr. A. P. LAURIE, M.A., "Oils, Varnishes, and Mediums used in the Painting of Pictures."

WEDNESDAY, MARCH 20, 8 p.m. (Ordinary Meeting.) JOHN B. C. KERSHAW, F.I.C., "Smoke Prevention in Factories and Electric Supply Stations."

Further details of the Society's meetings will be found at the end of this number.

CANTOR LECTURES.

Mr. F. HAMILTON JACKSON, Vice-President of the Society of Designers, delivered the third and last lecture of his course on "Romanesque Ornament," on Monday, 11th inst.

Mr. LEWIS DAY, Vice-President of the Society (the Chairman), proposed a vote of thanks to Mr. Jackson for his course, which was carried unanimously.

The lectures will be published in the *Journal* during the summer recess.

INDIAN SECTION.

Thursday afternoon, March 14; LORD AMPTHILL, G.C.S.I., G.C.I.E., in the chair.

The paper read was "The City of Madras," by SIR JAMES THOMSON, K.C.S.I., M.A., late Member of Council, Madras.

The paper and report of the Discussion will be published in a future number of the *Journal*.

ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal for 1907 early in May next, and they, therefore, invite members of the Society to forward to the Secretary, on or before Saturday the 6th April, the names of such men of high distinction as they may think worthy of this honour. The medal was struck to reward "distinguished merit in promoting Arts, Manufactures, and Commerce," and has been awarded as follows in previous years:—

In 1864, to Sir Rowland Hill, K.C.B., F.R.S.

In 1865, to his Imperial Majesty, Napoleon III.

In 1866, to Michael Faraday, D.C.L., F.R.S.

In 1867, to Mr. (afterwards Sir) W. Fothergill Cooke and Professor (afterwards Sir) Charles Wheatstone, F.R.S.

In 1868, to Mr. (afterwards Sir) Joseph Whitworth, LL.D., F.R.S.

In 1869, to Baron Justus von Liebig, Associate of the Institute of France, For.Memb.R.S., Chevalier of the Legion of Honour, &c.

In 1870, to Vicomte Ferdinand de Lesseps, Member of the Institute of France, Hon. G.C.S.I.

In 1871, to Mr. (afterwards Sir) Henry Cole, K.C.B.

In 1872, to Mr. (afterwards Sir) Henry Bessemer, F.R.S.

In 1873, to Michel Eugène Chevreul, For.Memb. R.S., Member of the Institute of France.

In 1874, to Mr. (afterwards Sir) C. W. Siemens, D.C.L., F.R.S.

In 1875, to Michel Chevalier.

In 1876, to Sir George B. Airy, K.C.B., F.R.S., Astronomer Royal.

In 1877, to Jean Baptiste Dumas, For.Memb.R.S., Member of the Institute of France.

In 1878, to Sir Wm. G. Armstrong (afterwards Lord Armstrong), C.B., D.C.L., F.R.S.

In 1879, to Sir William Thomson (now Lord Kelvin), O.M., LL.D., D.C.L., F.R.S.

In 1880, to James Prescott Joule, LL.D., D.C.L., F.R.S.

In 1881, to August Wilhelm Hofmann, M.D., LL.D., F.R.S., Professor of Chemistry in the University of Berlin.

In 1882, to Louis Pasteur, Member of the Institute of France, For.Memb. R.S.

In 1883, to Sir Joseph Dalton Hooker, K.C.S.I., C.B., M.D., D.C.L., LL.D., F.R.S.

In 1884, to Captain James Buchanan Eads.

In 1885, to Mr. (afterwards Sir) Henry Doulton.

In 1886, to Samuel Cunliffe Lister (afterwards Lord Masham).

In 1887, to HER MAJESTY QUEEN VICTORIA.

In 1888, to Professor Hermann Louis Helmholtz, For.Memb.R.S.

In 1889, to John Percy, LL.D., F.R.S.

In 1890, to Dr. (now Sir) William Henry Perkin, F.R.S.

In 1891, to Sir Frederick Abel, Bart., G.C.V.O., K.C.B., D.C.L., D.Sc., F.R.S.

In 1892, to Thomas Alva Edison.

In 1893, to Sir John Bennet Lawes, Bart., F.R.S., and Sir Henry Gilbert, Ph.D., F.R.S.

In 1894, to Sir Joseph (now Lord) Lister, F.R.S.

In 1895, to Sir Isaac Lowthian Bell, Bart., F.R.S.

In 1896, to Prof. David Edward Hughes, F.R.S.

In 1897, to George James Symons, F.R.S.

In 1898, to Professor Robert Wilhelm Bunsen, M.D., For.Memb.R.S.

In 1899, to Sir William Crookes, F.R.S.

In 1900, to Henry Wilde, F.R.S.

In 1901, to HIS MAJESTY THE KING.

In 1902, to Professor Alexander Graham Bell.

In 1903, to Sir Charles Augustus Hartley, K.C.M.G.

In 1904, to Walter Crane.

In 1905, to Lord Rayleigh, O.M., D.C.L., Sc.D., F.R.S.

In 1906, to Sir Joseph Wilson Swan, M.A., D.Sc., F.R.S.

A full list of the services for which the medals were awarded was given in the last number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

FOURTEENTH ORDINARY MEETING.

Wednesday, MARCH 13th, 1907; LEWIS FOREMAN DAY, F.S.A., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Anderson, James D., 17, Blakesley-avenue, Ealing, W.

Booth, Rev. James Henry, F.R.G.S., Maryport, Cumberland.

McIlwraith, Sir Malcolm, K.C.M.G., Ministry of Justice, Cairo, Egypt.

MacLean, John, 330, Smith-street, Winnipeg, Canada.

Muff, Henry, The Red House, Bexley Heath, Kent.

Wyllie, Herbert D., Cameron Septic Tank Co., 812 & 813, Monadnock Block, Chicago, Illinois, U.S.A.

The following candidates were balloted for and duly elected members of the Society:—

Charlesworth, Charles Dixon, 72, Egerton-road, Withington, Manchester.

Euba, Rev. W. B., Wesleyan High School, Marina, Lagos, West Africa.

Firminger, Rev. Walter K., B.D., M.A., Kidderpore Vicarage, Calcutta, India.

Robertson, Vincent Leopold, Rolfontein, P O. Amersfoort, Transvaal, South Africa.

Tebb, William Scott, M.D., Sandfield, Putney Heath-lane, S.W.

Wallace, Captain William Thomas Ewart, Entebbe, Uganda Protectorate, British East Africa.

The paper read was—

MEDIÆVAL STAINED GLASS: ITS PRODUCTION AND DECAY.

By NOEL HEATON, B.Sc.

I am not going to attempt to-night to give you a complete account of the methods of mediæval glass painting, but to draw attention to various points connected with this subject which I have recently had an opportunity of studying. My inquiries, conducted in the brief intervals of daily work, have been of necessity spasmodic and incomplete, but I venture to put before you the conclusions at which I have arrived in the hope that they may be of some interest, and that they may be favoured with your discussion and especially your criticism. Before entering on my subject, however, I propose, with the indulgence of those of you to whom such things are perfectly familiar, briefly to recapitulate the main facts concerning the composition and manufacture of glass, in order to render clearer the points on which I wish to invite discussion, to those of you who may not have had the opportunity of studying such matters.

In the following Table I have attempted to give a summary of the main principles of glass making*:—

The principal constituent of glass, from which most of its characteristic properties are derived, is the substance silica, found in almost all rocks, and occurring almost pure in such substances as quartz, flint, &c. Nowadays fine white sand, which is almost pure silica, is generally employed as its source in glass-making.

* It will be understood that I have only touched upon this on the broadest lines with a view to exhibiting the relations between the various materials to which I shall have occasion to make frequent reference.

TABLE I.—THE COMPOSITION OF GLASS.

Class.	Substance.	Composition.	Source.	Function.	Faults.	Type. Potash lime.	Soda lime.	Flint.
Acid	Silica	SiO_2	Quartz Flint White sand	Glassy nature	Infusibility	70	70	43
Alkalies	Potash Soda	K_2O Na_2O	Wood ashes Glaubers salt, &c.	Fusibility	Solubility	15 —	— 15	12 —
Alkaline earths	Lime Baryta Magnesia	CaO BaO MgO	Chalk Barytes Limestone	Brilliancy Durability	Tendency to devitrify	13	13	—
Earths ..	Alumina Iron Manganese	Al_2O_3 Fe_2O_3 MnO	Clay — Black oxide	Brilliancy — Corrects colour	Excessive hardness Colour [?]	2	2	2
	Lead oxide	PbO	Red lead	Optical qualities	Softness and weight	—	—	43

Silica possesses in a very marked degree all those qualities which one looks for in glass, with one serious drawback, that it only becomes plastic at a temperature far too high for the ordinary conditions of working.

Glass, in fact, is silica, rendered more fusible by combination with other substances.* These substances are, in the first place, the alkalies, potash and soda. These two alkalies, potash and soda, are very similar in their properties and yet have important differences. The name potash, by the way, is a contraction of pot-ashes, because it was originally obtained by collecting the ashes of burnt wood in an iron pot and extracting the salts with hot water. Potash, it is important to remember, is the principal ingredient of the ash that remains after burning any land vegetation. Soda, on the other hand, is chiefly marine in origin, being the principal constituent of sea salt and of course our common table salt, which is derived from it.†

Unfortunately, these alkalies, although capable when heated with silica, of combining with it to form a fusible glass, are unable to accomplish this without rendering it useless in another direction, the glass so made being soluble in water and easily disintegrated by exposure to the weather. In order to counterbalance this tendency we have recourse to the bodies known as alkaline earths, which, combined with the materials already mentioned, yield a practical glass, which is both fusible and insoluble. Where a glass is required which will be extremely resistent, alumina, the oxide of the metal aluminium, may be used, but this makes the glass exceedingly hard if added to any great extent. These are all the essential constituents of white glass—you see, however, I have also included iron and manganese in the list. They are not wanted, but except in special cases where great care is taken to exclude it, iron always manages to find its way into glass, as an impurity in one of the ingredients, and gives a colour to the glass which, when pure white glass is required, is generally counteracted by the addition of manganese.

It is also possible to produce a satisfactory glass in another way, by means of lead, which can be used instead of the earths; we do not, however, find lead used for glass-making during the mediæval period.

It is not necessary to have all these materials present in a glass, but it is necessary to have silica, one alkali, and one of the earths or lead—several kinds of glass are, therefore, possible, but in practice three types are generally recognised, namely: — Potash-lime, the mediæval type; soda-lime, its modern equivalent; potash-lead, modern flint glass.

* This is only strictly true of such glasses as are commonly used for domestic purposes. There are other varieties of glass—such as those used for optical purposes, and for making enamels—where silica may be largely replaced by its congener boron oxide. But these belong to a different category, and do not come within the scope of my paper.

† The chief source of soda in ancient times was Natron, a natural carbonate of soda, which occurs as a deposit on the sides of several lakes to the west of the delta of the Nile. The name alkali which includes both potash and soda, is derived from Kali, the name given by the Arabs to a plant which they used extensively as a fuel. The ashes from the fires so made they collected and sold to the Venetians for glass making. "Of the glass we use the purest is made of the ashes of chali or glasswort" (Sir Thomas Browne, "Vulgar Errors.")

This, of course, all has reference to white glass; the production of coloured glass I do not propose to touch upon.

Turning now to the various methods employed to make the glass into the flat sheets in which it is required by the glass painter, these may be divided into three:—

1. The simplest and, therefore, probably the earliest method, was that generally employed by the Romans for making window glass, namely, by just pouring the molten glass on to a hot marble or metal slab.

2. The next method, the one most commonly employed by mediæval glass painters, consisted of blowing the glass into a bulb, manipulating this until it took the shape of a cylinder, and, by a subsequent operation, opening this cylinder out into a flat sheet; this is generally known as "muff" or cylinder glass.

3. Then we have the spun or crown glass, which begins in the same way as the muff, but ends in the formation of a flat circle with a boss, or bullseye as it is called, in the centre.

Now, there are two curious things about these different methods of making glass into sheets. One is that the Romans, who were capable of doing almost anything with glass, are generally supposed to have been unable to make, or at any rate not to have made, window glass in any other way than by casting it into sheets in the way I have described. It is surprising, I think, that they should have stopped there, in view of the fact that they made window glass purely for utilitarian purposes, for which the blown glass is far superior to the rough cast glass that they used. Now, on the contrary, the mediæval craftsmen were indifferent glass makers, and I think it equally extraordinary that they should jump straight away to the comparatively difficult process of making muff glass; yet the earliest direct evidence we have as to their methods, the well-known treatise of Theophilus, describes, clearly and unmistakably, the "muff" process as the way to make glass in sheets.

As regards the first fact, quoted categorically by all writers on the subject that I have seen, that Roman window glass was invariably cast, the explanation is simple—it is not true. The Romans undoubtedly knew how to make muff glass, and muff glass of Roman make was used in England. It was probably a much later development than the cast glass they more generally employed, it is certainly a much better and finer glass, but it certainly existed. I do not wish to go into this point at length because it is somewhat wide of my subject, but I would like those interested in the matter to examine this specimen of undoubted Roman window glass from Silchester, which, by the courtesy of Mr. G. H. Fox, to whose kindness I owe my ability to make this statement, I am enabled to show you.

I think I may assume then that the Romans made "muff" glass, and this might perhaps explain away the second difficulty I referred to by assuming that the art of making this glass was handed down through the dark ages of which we know so little. I scarcely think this is probable however; to give one reason, the mediæval glass itself is far inferior to the Roman, and made with quite different materials, whereas one would expect that if the manipulation were handed down, the process of manufacture would be also.

No, I believe that the mediæval glass must be taken by itself, and I think it most probable that it originated in the first instance in the simple process of pouring the glass on to a slab. In the absence of sufficient evidence I should be sorry to state this as a fact—unfortunately authentic specimens of stained glass earlier than the thirteenth century are not common, and it is exceedingly difficult to procure isolated fragments for examination; but I possess one specimen of early thirteenth century glass, which I am quite convinced was made in this way—this fragment here—which came from Noyon in France.*

As regards the spun glass, it appears to date back as far as the muff—which came first I cannot say; it is quite possible that one developed out of the other almost simultaneously. One finds muff and spun glass side by side in the late twelfth and thirteenth century windows, muff glass generally employed for white, blue, yellow, and flesh glass which were used in quantity, and spun for ruby and the finer colours.

But to return to the matter of the making of the glass, as regards the actual ingredients employed and the composition of the glass resulting.

The earliest account we have of this is the celebrated treatise of Theophilus, to which I have already alluded, wherein we read:—

"If it pleases you to make glass, first cut up much beech wood and dry it well. Then burn it equally in a clean spot, and diligently collecting the ashes, be careful not to mix any dust or stones with them. . . . ."

* This specimen was sent to me by my brother, Mr. Clement Heaton, of Neuchatel.

"Then taking two parts of the ashes of which we have spoken above, and a third of sand, carefully purified from earth and stones, which sand you shall have taken out of water, mix them together in a clean place."*

On the face of it then, the making of mediæval glass was perfectly simple. One can readily understand, however, that as to whether the glass was good or bad, a great deal depended upon the actual composition of these two ingredients, wood-ashes and sand. Of course, one must be careful not to take the word of a single mediæval writer as representing all that could be said on the subject. What probably happened was this: that it being established as a general principle that glass could be made from sand and the ashes of plants (which are as I have said a source of alkali); then, whatever could best be obtained—beechwood, bracken, seaweed, or other vegetation would yield the ashes, and the nearest local deposit the sand.

Now, turning to the composition of wood-ashes, we find these words in a recent publication:—

"The composition of wood ashes is extremely variable: not only do different varieties of trees have varying quantities of ash, but in the same varieties the bark and twigs yield an ash quite different in composition to that furnished by the wood." Wiley, "Agricultural Analysis," vol. ii., p. 252.

Then as regards the sand, the source of the silica, it is only under exceptional circumstances that one finds white sand such as would be considered sufficiently pure for making glass nowadays: the ordinary yellow sand, formed by the disintegration of siliceous rocks, is not pure silica, but contains a varying proportion of other substances present in such rocks, namely, the earths, especially alumina. It is pretty certain then that mediæval glass varied very considerably in composition. Of course, this is nothing new, you probably have all heard it before. Considering these facts, however, one would expect mediæval glass to reveal on analysis a fairly complicated composition, and whilst varying considerably to show in general a richness in alkali (usually potash) and poorness in lime.

I have often contemplated the carrying out of a series of complete analyses of typical specimens of this glass, in order to obtain some information as to the relation of composition to decay, but have been prevented by the limited time and facilities at my disposal. One reads in Winston and other books on stained glass of numerous analyses of mediæval glass having been made. I have failed myself, however, to discover any detailed record of such work. When, therefore, an old friend of mine, Mr. Percy Williams, B.Sc., offered his assistance in this matter, I gladly availed myself of the opportunity.

As Mr. Williams possesses exceptional skill and experience in complex silicate analysis, and happened at the time to be particularly well placed for carrying out such tedious work, I place the results before you with far greater confidence in their absolute accuracy, than I should if I had attempted the work myself.

Two typical specimens of glass were taken, for both of which I am indebted to Mr. W. H. St. John Hope. The first was a fragment of some typical fourteenth-century glass from Sandiacre, in Derbyshire. This glass was in a very good state of preservation, as you see from this little panel, which contains some larger pieces of the same glass. The other specimen was some glass that had remained buried since the Reformation until dug up in 1882. It came from Dale Abbey, in Derbyshire. I consider it to be late thirteenth century, but as you see it is so much decomposed as to make it a matter of difficulty to determine. Here is a complete analysis of each specimen, and by the side I have noted, for comparison, what is considered to be the normal composition of modern window glass:—

TABLE II.—Composition of Mediæval Glass.

Material.	Sandiacre.	Dale Abbey.	Modern window glass
Silica	54·01	46·94	70
Phosphoric acid	4·18	4·11	—
Potash	13·20	16·96	15 (Potash and Soda)
Soda	1·70	0·12	
Lime	17·37	19·01	13 (Lime and Magnesia)
Magnesia	5·33	5·00	
Alumina	2·41	3·02	2 (Alumina, Iron and Manganese)
Iron	0·81	1·46	
Manganese	1·03	1·37	
Moisture due to decay	0·21	2·16	—

You see in each case the low content of silica as compared with modern practice; then you will notice that in each case the alkali is practically all potash, due to the use of wood ashes as I have already explained. There seems no doubt, by the way, that to this

* Theophilus. Book II., chapter I and IV.

use of potash instead of soda must be ascribed the glorious effect of staining obtainable in mediæval glass. It is not true that one cannot stain a soda glass, but the stain is much colder and harsher in the modern glass invariably made with soda. I am afraid, however, I must not stop to discuss this interesting question of stain to-night.

There are two points in these analyses to which, however, I would especially direct your attention. The first is the abnormal proportion of lime and magnesia, together amounting to 24 per cent. in the one case and nearly 23 per cent. in the other. I shall have occasion to refer to this point further in connection with the decay of the glass. In the second place I would draw attention to the presence of 4 per cent. of phosphorus in each case. This is rather an interesting matter in more than one direction, and so far as I am aware has not hitherto received attention.

In the first place it points to the fact that this glass was made in just the same way as described by Theophilus, that is, with crude wood ashes and sand. I think it has hitherto been considered somewhat doubtful whether or not the mediæval glass painters were accumstomed to purify their wood ashes before use. The presence of phosphorus in the glass, taken in conjunction with the large quantity of lime, suggests very strongly that this was not the case.

Owing to the extremely varying composition of wood ashes it is difficult to arrive at anything like a typical composition as regards quantities, but after potash the principal ingredients are the phosphates of lime and magnesia, which may amount to anything up to 40 per cent., in these, according to Liebig, the ash of beechwood is exceptionally rich. These insoluble substances would of course be left behind on lixiviating the ash to obtain the potash, and glass made with such purified alkali would contain no phosphoric acid.

The presence of phosphate of lime in this glass is interesting from another point of view. You know it is customary to speak of mediæval glass as being of a horny texture, and this texture is generally ascribed to its having been very imperfectly melted. For example, Winston says:—

"The difference . . . . . between modern and ancient glass is, I believe, occasioned by our using purer materials than the ancients did, and furnaces of greatly improved construction, which insures a more perfect fusion and amalgamation of the vitreous particles than perhaps could have been effected in the older furnaces."*

To judge from such mediæval glass as I have had the opportunity of carefully examining, however, I do not altogether agree with this: the glass seems generally well melted and homogeneous, although crudely blown. At the same time there is undoubtedly a peculiar opalescence or horniness about this glass which is not found in its modern equivalent.

Compare, for instance, the quality of the Sandiacre glass with the label beneath it, painted on modern "antique." This is just the quality that one would obtain by adding a small amount of phosphate of lime to the glass. I have here a lamp globe, for example, the peculiar opalescence of which is obtained by the addition of bone ash, that is, phosphate of lime, to the glass mixture.†

Then, from the point of view of the chemist, this presence of phosphorus in the glass is of interest. Taken in conjunction with the small amount of alumina and the large amount of lime, it renders the process of analysis very troublesome.

The importance of this point lies in the fact that if a partial analysis of the glass is made—with a view of determining the amount of alumina for example, or, if an analysis is attempted without the possibility of the presence of phosphorus being recognised, the results are liable to be seriously inaccurate.

In the case of an ordinary earth containing phosphorus, the ordinary method of analysis would not be interfered with, because the amount of phosphoric acid would be small relatively to the iron and alumina. The whole of the phosphorus in such a case would be carried down by the iron and alumina, leaving the alkaline earths to be dealt with in the usual way.

In the present instance, however, the reverse is the case—the iron and alumina are insufficient to bring down all the phosphoric acid, and the remainder would bring down part of the lime in this group. The analysis therefore would show much too high a content of alumina, and too low a percentage for lime. In order to obviate this difficulty Mr. Williams employed the following method of analysis:—

About 1 gramme of the glass was fused with five times its weight of fusion mixture, being first warmed

* "Inquiry," page 271.

† I am indebted to Mr. R. Plant, of the Soho Glassworks, Birmingham, for this specimen, and for showing me its process of manufacture in operation.

over a small luminous flame for a quarter of an hour, then over a bunsen flame for a quarter of an hour, and finally heated with a gentle blast for forty-five minutes.

After cooling, the platinum crucible containing the melt was digested for about three hours over the water-bath, and the contents washed out into a large platinum basin. The basin was covered with a watch glass, and 10 c.c. of pure nitric acid, previously diluted with 10 c.c. of water, introduced; it was then warmed over the water-bath, until the contents were completely disintegrated. The insoluble silica was then found to be strongly coloured by insoluble manganese dioxide; in order to reduce this and bring it into a soluble condition, the contents of the platinum basin were treated with about 1 c.c. of formic aldehyde. The reduction of the manganese proceeded slowly and was taken as being complete when the silica became perfectly colourless. The contents of the basin were then evaporated to dryness and finally heated in the air oven to 120°. After cooling, the dried residue was again digested with nitric acid (10 c.c. pure nitric acid diluted with 10 c.c. water), diluted, filtered, and the insoluble silica determined in the usual way. In order to correct for any soluble silica that might have passed into the filtrate, this was then again evaporated to dryness and taken up with nitric acid, the precipitate being added to the previous one. The final filtrate from the silica was then evaporated to dryness to expel nitric acid, and afterwards taken up with water and only sufficient nitric acid to ensure complete solution of the phosphates. This solution was washed into a flask, warmed over the warm bath, and treated with hydrogen sulphide to determine any traces of the metals of the lead group. After eliminating any dissolved hydrogen sulphide, it was allowed to cool and treated with excess of silver carbonate, well shaken during several hours, and filtered. The filtrate, after removing excess of silver with hydrochloric acid, contained the alkaline earths, which were determined according to usual practice. The precipitate contained the iron and alumina, all the phosphorus, and excess of silver carbonate. It was dissolved in nitric acid, the solution being then treated with hydrochloric acid to remove the silver, filtered, and precipitated with ammonia. This precipitate now consisted of the iron and alumina, combined with part of the phosphorus. The iron in this mixture was then determined, and also the phosphorus, and the alumina calculated by difference. The total content of phosphorus was subsequently estimated in a separate portion of the glass.

For purposes of comparison I now give you a typical analysis of the glass used by the glass painter at the present day—what is known as "Antique." This analysis I would remark, is not that of any particular specimen, but what you might describe as a fair sample of the type of glass. I collected specimens of white antique from various cutting shops, and reduced them to powder, making an intimate mixture of the whole, from which the specimen analysed was drawn.

TABLE III.

	"Antique." (Average.)	Mediæval. (Average.)	Normal window glass.
Silica..	67·1	50·47	70
Phosphoric acid.	—	4·15	—
Sulphuric acid ..	0·6	—	—
Potash	0·7	15·08	15 (Potash and Soda)
Soda	12·5	0·91	
Lime	12·5	18·19	13 (Lime and Magnesia)
Magnesia	0·1	5·16	
Alumina	5·0 (Alumina and Iron)	3·85	2 (Iron and Manganese)
Iron			
Manganese ..	0·1	1·20	
Lead oxide ..	1·3	—	—

You see it is a much more normal glass according to our ideas.. The alkali is almost entirely soda, probably added in the making as sulphate of soda, to judge by the fact that a percentage of sulphur is found in the glass. The 1 per cent. or so of lead is probably due to the addition of cullet, containing some flint glass, to the batch. Side by side with this analysis I have placed the figures given by taking the mean between the two mediæval glasses previously shown.

But my original object in collecting these analyses was with a view to determine the relation between composition and decay, and I must now pass on to the consideration of this matter.

Mediæval glass, as you are aware, decays in a very characteristic manner. Very commonly the glass becomes covered with little pits, for all the world like the worm holes one often sees in an old oak cabinet; the appearance is, however, too well known to you to need description. The reason for this peculiar behaviour seems to have been often speculated upon, but rarely inquired into. The pitting of the surface has been likened to small-pox, and I remember a few years ago, when some of the York windows were undergoing repair, an alarming account of their condition appeared in one of the daily papers, from which it appeared that this pitting was due to a malignant microbe which started a regular disease through the glass. Of course, this probably originated in a practical joke on the part of one of the artists in charge of the restoration; but I have seen suggestions almost

as wide of the mark put forward quite seriously and quite recently.

So long ago as 1879, however, a paper was contributed to the Society of Antiquaries* on this subject, which. although incorrect in many details and somewhat unnecessarily complicated, gives a very complete survey of the matter. It is much to be regretted that the large number of examples collected together in illustration of this paper were not kept together for future reference, and are now only to be judged by the brief descriptions of them there given.

The process of decay in glass is undoubtedly a parallel on a small scale to the change produced on a large scale by the action of time and weather on geological formations, such as chalk and sandstone—a combination of corrosion and internal change. In fact, to study the decay of glass is to study structural geology under the microscope, to put it metaphorically.

In the first place, glass—especially that made with potash, as all mediæval glass was—is hygroscopic, attracting moisture to its surface, so that except in a very dry climate it is never perfectly dry, but covered with a film of moisture. This water immediately attacks the surface of the glass, extracting the alkalies from the alkaline silicates, and leaving the silica behind. Of course, this action is very slight, but it is quite possible to demonstrate that it takes place by leaving glass even for a few minutes in contact with moisture.†

Allow this process to go on unchecked for year after year, century after century, accelerated by actual exposure to rain, frost, and snow, by the presence of acids dissolved in the water, and by continual variations of temperature, and you will find that the effect of the action accumulates until the whole surface of the glass gradually becomes corroded away, as you can see it is in this specimen of the glass from Sandiacre. The alkalies being entirely extracted from the surface the silica is left behind, and in glass exposed to the weather, as this has been, is washed away. If, however, the glass is not exposed to actual washing—if it is buried for instance—the silica remains on the surface in a thin film, so thin that like the soap bubble it interferes with the light passing through it, producing that irridescence which is so admired on specimens of ancient buried glass. It is only very rarely, however, and under exceptional circumstances, that mediæval glass becomes irridescent by corrosion, an this is due to the large proportion of lime it contains as compared with the silica and alkali. On the extraction of the alkali by water this lime is left behind with the silica and forms with it a hard insoluble silicate of lime, which adhers to the corroded surface of the glass, forming an opaque scum or patina, as is also well illustrated by this Sandiacre glass. In some cases this is so marked that the glass appears to be covered with a coat of cement. There are instances of this, for example, in some of the glass from the Sainte-Chapelle in the Victoria and Albert Museum, of which by the kindness of the authorities I was recently enabled to make a careful examination.

This scumming of the glass has given rise to the suggestion, put forward by Winston and others, that mediæval glass was sometimes coated with mortar when first made in order to imitate decay. I submit to you that mine is the more tangible explanation. I have no doubt that the craftsmen of the Middle Ages were capable of such a thing if it occurred to them, but I think we must give them the credit of being ignorant of modern ideas of faking, and of descending to such mean and unworkmanlike tricks.

So much, then, for the direct corroding effect of the atmosphere on glass. Side by side with this corrosion of the surface we find that exposure to weather and variations of temperature has another indirect influence, which produces internal change. You must remember that glass is not a definite chemical compound, but an indefinite mixture of different silicates.

It is well known that if glass is kept for a length of time at such a temperature that it is just plastic, its constituents tend to separate out into definite compounds, which crystallise out from their matrix in the same way as any salt will crystallise out from solution, until in time the glass changes entirely into an opaque, crystalline mass, generally known as Réaumur's porcelain, because Réaumur conceived the idea of utilising this action to produce articles having a general resemblance to porcelain.

Now it sometimes happens that glass com-

* "The Process of Decay in Glass."—James Fowler, F.S.A., Archæologia, vol. xlvi.

† An electroscope mounted on glass insulators will not retain a charge of electricity for any length of time in an ordinary room; if, however, precautions are taken to keep it absolutely dry it can be kept charged for a considerable period. This is due to the fact that in the first case the film of moisture on the glass attacks it and becomes alkaline, so providing a conducting surface along which the charge can escape.

mences to crystallise out in this way whilst it is being worked, from various causes affecting the working of the furnace. The glass-blower's name for this state of affairs is that the glass has turned "ambitty." This accident has been turned to account in the production of a glass called ambitty sheet, with which all glass painters are familiar; it is very extensively used for domestic plain glazing. The peculiar texture of this glass is due to the presence of numerous minute crystals, which can readily be distinguished with a pocket lens, whilst the microscope reveals the presence of several distinct compounds with definite crystalline forms.

You see then that it does not take much to make glass change its constitution, and what happens in a few hours when the glass is hot tends to take place on prolonged exposure to the atmosphere, with this difference, that when the glass is molten its molecules can freely move about, whereas, when it is cold and rigid such freedom of movement is impossible; in consequence the definite formation of crystals cannot take place, and the result of the change is different. What happens is this. In the first place molecules of the same kind tend to separate out from the homogeneous mixture and collect round a point, forming a centre of decomposition. The action in fact is just the same as the formation of concretions in sedimentary rocks—such as the formation of flint in chalk—and as you find that these concretions generally form round some object which provides a nucleus, so you generally find that if there is any irregularity such as a scratch on the surface of the glass, the decomposition will proceed along the line of that scratch.

Proceeding from this centre we find the glass decomposing into definite compounds in an ever enlarging circle until it reaches a point at which the strain set up in the glass by this molecular movement results in a crack forming round the area of decomposition and then the whole mass comes away, leaving behind it a little hole or pit in the surface of the glass. These pits are more or less circular as a rule, but frequently they grow close together and the edges unite, forming an irregular shaped hole. The pits vary in size from microscopic dimensions to a quarter of an inch in diameter, but as a general rule they are about the size of a pin's head. The most remarkable case of pitting I have ever seen is that of some of the York windows, fragments of which have been shown to me by Mr. Grylls, where the pits reach a diameter of over ⅜ths of an inch and a depth of nearly ⅛th of an inch. When pits are forming along a scratch they generally develop close together, side by side along it, and the adjacent sides break down, so that in the end we have an excavation in the shape of a long trough.

This I am convinced is the explanation of the pitted surface of old stained glass. That there certainly is a change in the constitution of the glass is shown by the fact that on digesting glass which has begun to decay in this way, in hydrochloric acid, it is possible to extract the whole of the alkalies and earths, leaving a skeleton of pure silica in the form of the original glass, whereas fresh glass of the same composition is not attacked by hydrochloric acid to any extent.

Mr. Williams, who first made this experiment, has obtained the same result with certain varieties of asbestos, which is produced by the devitrification of natural volcanic glasses. Glass devitrified by heat is also attacked by hydrochloric acid in the same way.

With the aid of the microscope one can follow out the whole process of the formation of pits in mediæval glass in the way I have described, and I now put before you several illustrations of the process, and its relation to that of devitrification.

No. 1 is a piece of Ambitty sheet glass; (*a*) natural size, showing the sparkle caused by reflection of light from numerous microscopic crystals; (*b*) magnified 20 diameters, showing three distinct crystalline compounds, the crystals having been broken up and interwoven by the manipulation of the glass. (Fig. 1.)

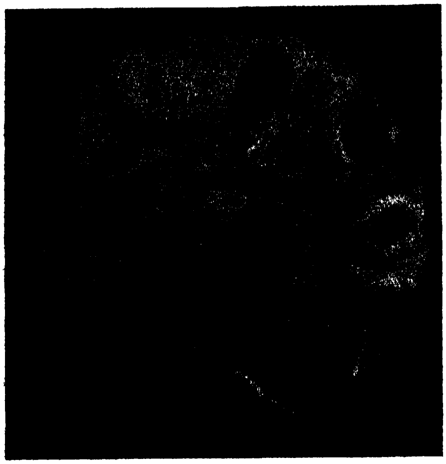
No. 2 is the fragment of early thirteenth century glass, from Noyon, magnified 20 diameters, showing long acicular crystals disseminated through it.

No. 3.—A piece of ordinary sheet window glass, which has been devitrified on the surface by heating in a glass painter's kiln for several hours. To the naked eye the surface appears covered with a multitude of circular white spots. (*a*) The upper surface, magnified 20 diameters: shewing acicular crystals growing in tufts from a centre, the strain set up by this change of formation resulting in cracks radiating from the same centres. (Fig. 2. (*b*) The under surface of the same glass, which was in contact with the bed of whitening during the heating, shewing the influence of lime on the character of the crystals.

No. 4.—A piece of flashed purple — probably early sixteenth century; the flashed

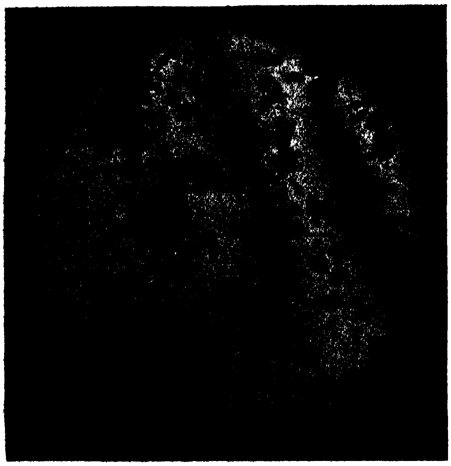
surface quite bright and free from corrosion but studded all over with numerous well defined pits, suggesting that such pits are internal rather than external in origin.

FIG. 1.



No. 5.—A fragment of stained glass from St. Peter's, Derby, shewing pits in course of formation. (*a*) Natural size. (*b*, *c*, *d* and *e*, Figs. 3, 4) Micro-photographs of pits in various stages, shewing growth from a centre in a similar manner to No. 3*a*.

FIG 2.



Such, then, are the two forces at work on the decay of glass—corrosion without and decomposition within, and of course they act simultaneously. As the pits are formed they are extended by corrosion, forming a resting place in fact for the water, until eventually the whole fabric of the glass is destroyed.

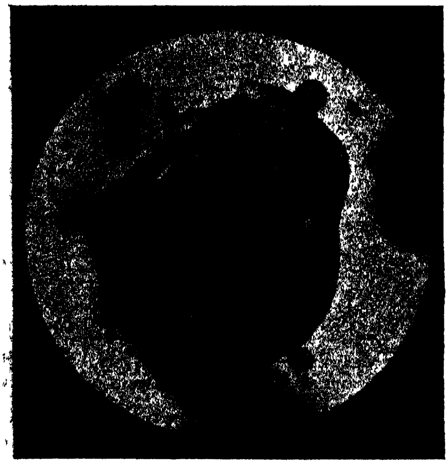
According to varying circumstances—the position of the window as affecting its degree of exposure—the climate in which it is placed —differences in composition and mechanical

FIG. 3.

state of the glass, we get all sorts of variations in the precise effect of decay in particular instances.

It is a well recognised fact that glass containing a large proportion of earths, that is, lime, magnesia, and alumina, is specially

FIG 4.



liable to turn ambitty. If, then, I am correct in thinking that the peculiar pitting of Gothic glass is due to a similar change of constitution, one would expect to find it excessively rich in these constituents, and we have already seen that this is in fact the case.

On the other hand, glass containing excess

of alkali has an equally recognised tendency to go "blind," tnat is, to become covered with a film, due to corrosion—the surface of water glass, consisting of soda and silica only, to take an extreme case, becomes roughened by corrosion in a few days. Finally, glass with a high content of silica, with earth and alkali equally balanced, may be looked upon as highly resistent in both directions. It is such glasses which decay slowly and with little tendency to devitrification, the surface being merely etched by corrosion, leaving the large proportion of silica in a coherent thin film, producing gorgeous effects of iridescence.

Of course one must not overlook the fact that apart from composition the mechanical nature of the glass has an influence on decay. Just as a geological formation of regular and uniform nature resists corrosion better than one of varying hardness and character, so a glass of uniform texture resists decay better than one of the same composition but full of variations. Now I pass on to say a few words about the "colour" as we call it, used to paint on the glass in mediæval times. If one is struck by the fact that the older the glass is the freer it seems to be from decay, how much more is this the case with the colour. On making a careful examination of the Sainte Chapelle glass to which I have already alluded, I found that the painting of the original glass was as sound and perfect as when first put on early in the thirteenth century. Here and there, however, were pieces where the paint had either gone entirely, or showed unmistakeable signs of decay, but in every single instance, careful examination revealed the fact that the glass was an insertion of later work. The most glaring case of this is one of the heads, which no one who has seen this glass can have failed to notice as being later in date than the rest of the glass. Half the paint on this head has already gone, and I would undertake to wipe the glass clean by rubbing it with a damp rag. Possibly the explanation of this may be that all the bad work of the thirteenth century has already disappeared and only the best remains, but there is no doubt that the mediæval craftsmen could make their colour so as to last remarkably well.

In this respect, however, I consider they are equalled by the best colours of to-day. But that is not all; there is a peculiar texture about the old colour, a vigour in the very finest lines, and yet a general feeling of warmth and transparency, which one has great difficulty in producing to one's satisfaction. Any hint one gets as to the method of production of this colour therefore demands careful investigation.

Now on looking through the various exchequer accounts, many of which are extant, connected with the glazing of church windows, one is struck by the constant reference to a material called "geet," bought for the purpose of painting the glass—"Geet pro pinctura vitro." The actual nature of this material does not seem to have been thoroughly inquired into, and my attention having been drawn to it in course of conversation with Mr. C. W. Whall, I thought an investigation of the matter might possibly prove to be of value.

I now want to put before you what is actually known about this material called "geet," and my conclusions regarding it, and I will begin by showing you a selection of extracts from the accounts I have mentioned :—

"Pro stangno Get et operacione fenestrarum et stipendiis de verrers usque festum sancti Michiaelis, 32s. 9¾d. Pro verre empt., £5 os. 2¼d." (Norwich Sacrist's Roll. A.D. 1274-5).

"Die Lunæ ix° die Julii. Johanni-Geddyng pro vj libris de Geet emptis pro pictura vitri vj*s*. pro cervisia empta tam pro congelacione vitri quam pro mensis vitriariorum lavandis viij*d*. Eidem pro lymatura argenti empta pro pictura vitri viij*d* Willelmo de Newerc pro cc. Talshid emptis pro vitro anellando et frangendo pretium centenæ vij*s*.-xiiij*s*. Johanni Madfray pro j. libra de Gum arebik empta pro pictura vitri iij*d*. Ricardo Thorp pro xv. centenis vitri diversi coloris pretium centenæ xl*s*.-xxx*li*. In portagio et batillagio ejusdem vitri de Temesestreete usque Westmonasterium x*d*.

"Summa empcionum xxxj*li*. ij*s*. v*d*."

(Exchequer Accounts, St. George's Chapel, Windsor, A.D. 1351-2.

"Iu xij peys vitri diversi coloris empt', xij s. In geet et lymail empt' ad vitrum, iij s. iij d." (Ely Cathedral, A.D. 1357.)

Similar references to "geet" appear in the accounts for the glazing of the windows of St. Stephen's Chapel, Westminster, which Brayley and Britton sum up thus :—

"Large quantities of stained glass of various colours, as blue, red, azure, and white, were used in glazing the windows; and silver filings, geet [probably jet], and arnement [orpiment or yellow arsenic], are mentioned among the materials procured for painting on the glass."—History of the Palace of Westminster, page 180.

To come to a later date, we have the "Booke of Sundry Draughtes," by Walter Gedde, 1615, wherein we read :—

"The Receipets, for the true making of Collours for Glasse. To make a faire Blacke. Take the Scales of Iron & Copper, of each a like waight, & put it in

a cleane vessell that will indure the fire, till they be red hotte, then take halfe as much Ieate, and stamp them into smal pouder, then mix them with Gumwater, & grind them fine vpon a painters stone and so drawe with it vpon your glasse."

And again :—

"Carnation.—Take two ounces of Tyn-glas, and six ounces of Ieat, half an ounce of gum, ten ounces of red Ocker, and grind them very well together, and so use it."

"To Make a Grey couller, take Iron scales, a little Cristall, and sum smale quantitie of Ieate, grind these well together upon a painters stone, the more Ieate ye take, the sadder the coullour will be, and likewise the more christall you put to it the lighter."

From the middle of the thirteenth century to the beginning of the seventeenth century we find this substance geet in use. It is true, however, that the treatise of Theophilus, which would be somewhat earlier than any of the dates quoted, makes no reference to it, but states that the colour is to be made of copper scales, green glass and "Greek sapphire" in equal proportions. (Book ii., chapter xix.)

The extracts quoted undoubtedly convey the impression that "geet" must be taken to mean jet—an impression strengthened by the fact that the word geet is constantly used by mediæval writers, where from the context jet is undoubtedly referred to. Hence we find that from Brayley and Britton to the present day, it has been taken for granted that the mediæval glass painter painted his glass with ground jet. But the point is not the name they gave to their material but what it was—was this stuff they called jet, what we mean by jet at the present day? On the face of it, to a practical man, it seems improbable. Let me give you a short account of jet condensed from various authorities.*

The name jet is supposed to be a corruption of "gagates," the name given to this substance by Pliny, who described it as found near the mouth of the River Gagas; the hardest, and therefore best jet, is found in this country principally at Whitby and Robin Hood's Bay.

Its use appears to have been known in this country from a remote period; it frequently occurs amongst the relics found in ancient British barrows, and in Roman and Saxon tombs; it is also frequently mentioned in mediæval wills and other documents down to the present day.

In composition it resembles cannel coal, but, it is harder, blacker, and takes a brighter polish, and like coal, consists mainly of hydrogen and carbon. It readily ignites and burns when heated, and on dry distillation yields a quantity of dark oil.

Jet, therefore, does not sound a very promising material for use in glass painting; but in such a case as this, whatever theoretical conclusion one may come to, the only really reliable argument is practical experiment. I therefore decided to see what sort of glass colour one could prepare from jet. For this purpose I obtained a number of specimens from various sources, namely:—

1. A lady's hat-pin, purchased from the street vendors of jet at Whitby.

2. Some specimens of jet collected from the cliffs at Whitby by Dr Andrea.

3. A large piece of unworked jet, obtained from a merchant at Whitby.

4. A brooch and other articles made of jet.

5. Some fragments of Roman jet, from Silchester.

6. A number of jet beads.

I made up some pigment with samples of all these different jets according to the recipe given by Walter Gedde; the result obtained was just as I expected in theory. On putting the glass painted with this "faire black" in the kiln the colour ignited and burnt away like tinder, leaving a slight residue behind which could be readily rubbed off the glass with the finger; jet, as a material for painting on glass, is perfectly useless.

But one may perhaps assume that for "geet" we should read the ashes of jet—the residue left after burning, in the same way as wood ashes were used for making glass. In order to test this I made analyses of these specimens of jet, of which the following may be regarded as typical :—

Moisture	1·56	per cent.
Volatile matter	66·15	"
Coke	29·96	"
	97·67	"
Ash	2·33	"
	100·00	

This ash contained the following :—

Silica, titania, &c.	40·6	per cent.
Iron, alumina and manganese	45·5	"
Lime and magnesia	4·8	"
Alkali	nil.	"
Undetermined	9·1	"
	100·0	

* See, for instance, this *Journal* xxii, p. 80 (Bower, "Whitby Jet and its Manufacture"), and xlix, p. 796 (Seward, "Structure and Origin of Jet.")

This is the analysis of Specimen No. 3, but the others (with the exception of No. 6, which I shall refer to shortly) yielded similar results. No. 5, for example, gave the following figures:—

Moisture	0·02 per cent.
Volatile matter and coke ..	97·85 „
Ash	2·13 „

Now I put it to you—is it probable that a hundredweight of a material of sufficient value to rank as a minor article of jewellery would be destroyed in order to obtain a couple of pounds or so of material for painting on glass, especially when you consider that the material so obtained would be quite useless for this purpose: as you see, it contains no alkali and over 50 per cent. of bases, and would require to fuse it a temperature at which the hardest glass would run like water.

But now I must tell you something—the matter might have ended there—I might have robbed the antiquaries of their beloved jet and left them nothing in its place, only it happened that amongst the specimens of jet I collected from my friends was a necklace of beads supposed to be of finest jet (Specimen No. 6); when I ground up these beads with iron oxide in the same way as the others and put a slip of glass painted with the mixture into the kiln, instead of burning away as I have described it melted and fired into the glass just as an ordinary enamel colour does, so that my glass came out painted "a faire black." Unfortunately, this was a forgery; it was not jet at all. Analysis shewed that it was just an artificial jet made of black glass.

But starting with this material as a basis, and altering the composition somewhat, I could produce a colour which exactly matched the old thirteenth century colour, and passed all the tests I could devise for permanency. Therefore I make the suggestion that the explanation of "geet" is this; that a glass resembling jet in appearance was prepared especially as a flux for painting on glass, which, mixed with the oxides of iron and copper, yielded the fusible pigment with which the mediæval glass was painted.

I admit that I have no direct documentary evidence of this. I have searched the records in vain for the slightest hint as to how or where the substance called geet was obtained, but I can mention several points in support of my contention. In the first place as far back as Roman times we find articles made of black glass and obsidian in imitation of jet. For instance, when I came to examine the fragments of Roman jet from Silchester, that I have referred to as being amongst the specimens examined (Specimen No. 5), I found that only one piece was true jet, the others being composed of a dark green glass with which I could make a glass painter's colour in the same way as with the artificial jet I have just described. The two materials were, however, so identical in appearance, that it was not until I was breaking them up preparatory to analysis that I discovered the difference.

One can readily imagine—of course, this is pure imagination—some mediæval worker making the discovery that a glass made in imitation of jet formed an excellent material for painting on glass, just as I discovered those imitation jet beads. This supposition is the more likely, however, because we have every reason to believe, that in the very early days the crafts of stained glass, enamelling, and the working in gold and precious stones were carried on side by side.

Having once been discovered, what more likely than that the artificial jet should be specially prepared for the glass painters and receive the technical name of "jet." As a parallel case I would mention black lead. As far back as I have been able to trace one finds this form of carbon referred to as though it were a variety of lead. Are we then to imagine that antiquaries of the twenty-sixth century, diving amongst the records of to-day, will argue that it was the custom of the period to cover our firegrates with a film of lead because they read of them being coated with black lead?

Another possible explanation is, that this substance was called jet in the same way as the various coloured glasses were often called by the name of the precious stone they most nearly resembled. For instance we read in Theophilus:—"Tabulas saphiri pretiosas, ac satis utiles in fenestris," Tabulas saphiri, meaning, undoubtedly, sheets of green glass.

Then you may perhaps have noticed in the receipts given by Gedde, the use of the word crystal. To make a grey colour, he says:—"Take iron scales, a little cristall, and sum small quantitie of Ieate." Now no one ever imagines that "cristall" means quartz, or anything else but white glass—why therefore can we not read for "Ieate" black glass?

One other piece of evidence I can offer you, which is this: If you grind up oxide of iron

with a soft white glass, which is a very common way of making glass-painters' colours, the fired glass shows under the microscope a mass of opaque black spots in a colourless matrix.

If, however, you examine mediæval "colour" under the microscope, it appears as a mass of black spots in a deep brown matrix. This also is the appearance presented under the microscope by the colour made up with black glass in the way I have just described; a colour which I have taken the liberty of calling by the name of "geet."

And that, I think, brings me to the end of what I have to say, and I must not detain you longer. Some of you may perhaps question the practical utility of such enquiries as I have discussed to-night; to such I would say—much has been done of late to revive the craft of stained glass, and place it once more in the dignified position it held in mediæval times, but more remains to be done. The bulk of the work must of course rest with the craftsman, on whom lies the responsibility for æsthetic conception. To such a position I cannot aspire; but the maker of materials can perhaps in a humbler way do his part. It is from this point of view that I have endeavoured to throw some light on the technical problems which face the glass painter, feeling that it is a privilege to be able to be of some use in such a cause.

And now I have only left the pleasant duty of acknowledging the help I have received from so many quarters in preparing this paper. I have already alluded to the invaluable assistance of my old friend Mr. Percy Williams, who really did most of the hard work for me; but it is largely due to the kindly encouragement and assistance of Mr. W. H. St. John Hope that I have been enabled to carry out these enquiries, the results of which I now lay before you.

DISCUSSION.

The CHAIRMAN said that a good many things had been explained by Mr. Heaton, which had previously puzzled him; for instance, the source of "scum." He had wasted a great deal of time in persevering ignorance, trying to clean old glass which was covered with the "scum" referred to, when he might just as well have tried to wash away the glass itself. *A propos* of the scum, nobody who had thought the matter out could doubt that the author must be right, and that Winston was quite wrong in his reference to the use of mortar, although, no doubt, the old workmen in times gone by did patch up windows with mortar, and sometimes it was found that old glass had had mortar rubbed across it. But he did not think it would be considered for a moment that they endeavoured to imitate glass, because there was no old glass for them to imitate. He thought Mr. Heaton gave too much honor to certain people in the past when he said they were above doing such unworkmanlike things as "faking." He, himself, had found faked leads in old grilles, which had been put up sufficiently far off to make deception possible. The glass had been painted in imitation of leads. He was much interested to hear of the possibility of extracting the earths and the alkalies from decaying glass, and so getting a skeleton of pure silica. With reference to the decay of glass, the slides shown had been most interesting. Mr. Heaton said that the older the glass the freer it was from decay. That, he thought, was what most of those present felt; and it was decidedly satisfactory to have that corroborated from the more scientific point of view. However, he still would like to know why that was so, and whether the older glass was harder, and got softer as time went on. The concern which artists possessed in the question must be considerable. The decay of glass did add greatly to the quality, and no doubt old glass was so much appreciated because of its decay. Of course it would be the wildest impracticability to suggest that they should make a glass which would decay just enough and no more than was required. What he thought glass-makers ought to devote themselves to was to produce a glass which was not too hard, but which should at the same time give an equivalent to what was obtained by weathering. He did not think that was scientifically impossible. No doubt old glass was made of all kinds of stuff, in a rough and ready way, and with very little scientific precision. Potash and other elements were used. The potash and soda were obtained from all sorts of vegetation, and the sand was of all degrees of impurity and the results were naturally "flukey." But some of the old glass did not decay; and that fact wanted some explanation. It had been found that some glass of a certain period was perfectly rotten, whilst other pieces looked quite new, although when closely examined, they were found to be old. With regard to the painting, he asked why black glass should be more permanent than white? If the flux which was used in it was of common, impure, and dark-coloured glass, that, for all he knew, must be harder than the white or more crystal glass. Was that so? As to the hardness or otherwise of the paint, there could be no doubt, for those who had inspected glass grilles which had been painted could see where the paint had decayed, and could trace the pattern by the preservation of the glass where it had once been covered by the paint. Upon the question of "geet," which was used as an addition to the paint, no doubt Mr. Heaton was

right—it could not have been jet. It might have been jet black glass. The question asked was, What made it black? and the answer had been subsequently given that it was iron and manganese. He was not quite convinced of the use of a special black glass for that purpose; partly, perhaps, because he did not see any necessity for it. He understood the author of the paper to say that where that had been observed through the microscope, it consisted of little specks of black, set in brown. It never occurred to him that the flux the old glass painters used for their paints mattered much. What he thought they were really bent upon obtaining was opacity, the only use of their paint being to stop out the light; and he supposed the copper and iron they used accomplished that purpose. He always thought that the old paint stood the best, because it was fired so hard, and painted more "brutally," and with more decision and emphasis.

Mr. HARRY POWELL, after stating that all interested in the subject of old glass were extremely indebted to the author for the labour he had bestowed on the question, thought Mr. Heaton was also to be thanked for having done away with the theory, which was so common, that the Romans had no blown sheet glass. It was always said that the Romans only used cast glass, but Mr. Heaton had proved most conclusively that they used sheet glass as well. The author had also referred to the interesting point that in the cast glass the bubbles were circular and not elongated. He had recently had occasion to examine the earliest forms of glass, so-called Egyptian glass; and when the little Egyptian vases were examined with the miscroscope, it was found that the bubbles were circular. Dr. Flinders Petrie was, therefore, right in his belief that the old so-called Egyptian vases were not blown, but cast. With regard to Theophilus, his impression was that he was a very intelligent man, but not a glass-maker. Theophilus visited glass works and gave a very interesting account of them, but like journalists, who described modern glass works, while they wrote a good deal of interesting matter, a good portion of it was erroneous. It was also very strange that while Theophilus gave an account of the manufacture of muff glass he ignored circle glass altogether, while his statements with regard to colours were most extraordinary. He did not think it need be supposed that muff glass originated before circle glass, but simply that Theophilus omitted to mention it. If early glass was examined it was rather difficult to tell exactly whether the glass originated as a muff or as a circle. But a good deal of the glass was so thick that it was almost certain to have been a circle glass, and some pieces had unmistakable marks of circles in them. He regretted the author had not investigated the question of the origin of the thirteenth and fourteenth century glass used in windows, because it would have been very interesting to know where the glass came from. It was known that a certain amount of glass came from Chiddingfold, but it was all white glass, there being no record of coloured glass having come from that place. It would be interesting to know whether all the coloured glass came from abroad, or whether some was made in England? With regard to the question of analyses of glass, his experience was that they were about the most fallacious things that existed. Glass was a most difficult substance to analyse, and he did not think he had ever known a glass actually reproduced from analysis. It would be a most valuable asset if details of really accurate analyses could be published. The great difficulty was that a large proportion of the alkaline constituents of the glass seemed to disappear, and a fallacious result was obtained. If a glass-maker attempted to make a glass exactly from an ordinary analysis, it usually would not melt. It had always been a source of immense regret to glass-makers that Winston's papers, giving the results of the many analyses made for him by Dr. Medlack, had never been found; what had become of them was a mystery. The author, in referring to the question of the opacity of old glass, attributed it to the large amount of phosphate of lime. His own experience was that phosphate of lime, by itself, would not produce opacity at all, some other ingredient having to be added to produce that effect. Phosphate of lime helped, but it would not produce opacity by itself. The large amount of magnesia and alumina in the glass were striking, and he thought both of those elements contributed to the horniness of the product. He considered his "horniness" of old glass to be due to physical rather than chemical causes. Mr. Heaton had not referred to one peculiarity of old glass, namely, that colour was very sparingly or hardly at all transmitted through it. It was curious that thirteenth century and early fourteenth century glass would hardly transmit colour at all. Another curious feature, as the Chairman had pointed out, was the smallness of the decay in old glass, some of it being as perfect now as it ever was. He attributed that to the fact that the old makers did not seem to mind in the least about ladling the glass. If it did not suit them they turned it out of the crucible into water, and performed the operation over and over again. He had no doubt that glass, however it might be put together, and however imperfect from the chemical point of view it might have been, if it was constantly ladled into water and re-melted, would at last produce an almost perfect compound. Where old glass had remained almost untouched, he had no doubt it had gone through several processes of re-ladling and re-melting. A year or two ago he was called down to Oxford to advise with regard to a disease very similar to the one to which the author had referred, which occurred at York. It was thought that some of the old fourteenth century glass windows were diseased, and would go to pieces, but, on investigating the matter, it was

found that the old glass was perfectly sound and good, but that some comparatively modern glass, 50 or 60 years old, had gone wrong. There was no doubt that an excess of some substance had been added during its manufacture, and the material had simply crystalised out. The Chairman had raised a question with regard to "geet." He did not think anybody, who had not made glass painters' colour realised how intensely opaque the colour had to be. No ordinary dark coloured glass is dense enough to be used as paint. He thought there was not the slightest doubt that the author of the paper was perfectly right in his contention that geet was merely intensely black glass, coloured very possibly with cobalt. Possibly it was used by the enamellers, who sold it to the glass stainers, and they worked it up in their paint.

Mr. C. W. WHALL, speaking from the point of view of the user of the material, stated that the author used the word "purified" with regard to the difference which existed between old and modern glass, stating that the old makers did not purify the wood ashes, as was done now. Speaking as a painter, he hoped the word "purified" would not be taken in the sense of necessarily adding a perfection to the article, because his feeling was that he wished painters could get their materials a little less pure sometimes. The tendency of the glass maker was to look at things from a scientific point of view, and to think that the more perfectly glass answered to some chemical formula the more perfect it was; but to the painter a good deal of what was called quality arose from the accidents and the imperfections of the material. The same thing occurred with regard to coloured glass. In buying glass from a manufacturer or merchant a particular glass was described as spoiled ruby, or spoiled pink, and he had often felt tempted to say when such were shown to him, "For goodness sake spoil some more." With regard to the question of the restoration of old windows and the proper way to treat them, taking it for granted that the quality which came from age was an added beauty, it was a subject of constant sorrow to see ancient windows treated as if that were a defect. The ordinary processes by which windows were cemented were very rough and drastic, consisting largely in scrubbing; but if old windows were looked upon in the light that they were just as precious as old pictures, nobody would think of employing the methods which were often at present adopted. What should obviously be done was to substitute the process of carefully puttying for the process of scrubbing it with ordinary cement in the way in which new glass was treated.

Mr. E. W. HULME stated that the subject of devitrification attracted the attention of the French artists in the sixteenth century; Palissy noticed that devitrification took place in the churches particularly in the south of France. According to the folklore of the people it was due to the moon's rays. It was particularly noticeable on the south side of the churches; the prevalent south-west winds carried more moisture, and where there was more moisture the glass devitrified sooner. It was quite wrong to think that window glass was made purely with potash at that period, because soda was then being used, and probably had been for some centuries. There was some evidence that there were two distinct schools of glass-makers at the time, one being the Normandy glass and the other the Lorraine glass, and possibly there was a third glass, the Bohemian. Glass painters asked for larger sheets of glass, and for more pellucid glass, and for that purpose soda was used in place of potash, and flint in place of the aluminiferous clay sands which were being used in other parts. In reply to Mr. Powell's questions as to where the window glass used in England came from, he thought most of it came from abroad. At Chiddingfold, green glass was made, but it was pretty certain they did not make a coloured glass. There was no reliable evidence that glass was made in England elsewhere than at Chiddingfold before 1563. He was aware that it had been stated that there was a school of Dutch glass-makers in Southwark in the reigns of Henry VII. and Henry VIII., who were credited with some of the most magnificent specimens of glass in this or any other country; but he had recently examined the documents upon which that statement was made, and had come across a document in which it was openly stated that the foreign glazier, Peter Nicholson, was not only using foreign glass, but actually bringing the glass, ready wrought, into the country. The Company of London glaziers complained, and they took the individual before the Star Chamber for breaking the laws of the realm, as it was a statutory offence to introduce ready wrought glass. That Southwark glazier employed both Dutch and English workmen, but it was very clear that nearly the whole of his glass came from abroad. The analyses given by Mr. Heaton were of very great interest because, he did not think he had ever seen it stated that phosphorus existed in so large a proportion in mediæval glass. In 1896, a very valuable work had been published by M. Appert, a great French writer, chemist, and glass manufacturer, on the subject of the composition of the glass of the old stained-glass windows. His view was that the resistance to devitrification of glass was due partly to the use of potash, but mainly to the use of alumina at that period. He advised those who were interested in the subject to read the work, although it was rather difficult to obtain as it was out of print.

Mr. JOSEPH LOVIBOND said that his interest was restricted to the relation of colour between the glass of the old windows and the glass of modern manufacture. He desired to ask the author if he had been able to trace any relation between the analyses of the two glasses and their colour variations? The more

refractory elements had increased in proportion, while the more soluble elements had decreased in proportion, which must be a very important effect upon the colour-evidence of the glass itself. A second cause which had been most ably treated in the paper was the alteration by surface erosion. In all the old glass he had examined there had been a very much wider range of surface erosion than had been shown by Mr. Heaton. It was quite manifest that the nature of the surface erosion must materially affect the colour developed. For instance, in some of the cases there were evidences of certain pits which were so close together as to form almost a regular surface. They acted as a disperser of light, and consequently destroyed the colour effects of the glass itself. The crystals might act as refractors, or even as condensers, and so alter the nature of the colour. He had been particularly interested in the effect the different changes had on the nature of the colour developed, although the question was so intricate and complicated that he was quite unable to throw any light upon the subject.

Mr. Walter Reid enquired whether the author had noticed any essential difference between the corrosion on the exterior compared with the interior surface of the glass, because that would at once throw some light upon the probable chemical cause of the erosion of glass. The circular form that was noticed, might possibly be due to some slight imperfections in the colour upon the glass, and, in that case, the corrosion would go on from the point outwards, and become circular. That was noticed in other substances, for instance, in iron. If once the coating of paint became injured pitting took place, and exactly the same structure was formed. When a metal of any kind was dissolved in acid the pitting which had been so clearly described by the author took place. There was no doubt whatever, from the slides that had been shown, that the pitting in some instances was due to the expansion of small bodies in the body of the glass, and if it were possible to get a microscope slide showing a section through one of the cavities, it would throw a good deal of light on the subject. It was highly probable that the corrosion was due to the solvent action of the carbonic acid of the atmosphere, the more so because in the earth, where the air was almost continually saturated with carbonic acid, the corrosion was so much quicker than it was when it was exposed only to the air. He thought it might possibly be due to the more continuous action of carbonic acid underground than when it was exposed to the atmosphere. It was also quite possible that in the case of the windows there was an electrolytic action. The glass was a non-conductor; it was surrounded by two or three metals, because there were soldered joints in many cases, and it was possible a slight electrolytic action was set up, which, after going on for a century or two, led to serious results upon the glass. With regard to the question of colour, it seemed to him that none of the old glass had a white base at all; it always had a greenish base. If a piece of common window glass were placed behind a piece of bright modern glass an effect similar to the older glass was obtained. Probably the sand that was used in the glass-making was very different from the qualities that were utilised now-a-days.

Mr. James Powell thought the remarks Mr. Whall had used with regard to the repairing of old glass were worthy of a good deal of consideration. He had lately been repairing some very beautiful fourteenth century glass, and in doing so he had not used a single piece of modern painting. A great deal of mischief had been done to old glass by putting in new pieces of coloured glass, contrasting with the old, and also by trying to imitate in paint some of the work of the early masters. He thought it was very important that the old work should be put together as soundly as possible in good lead, but that no new pieces of painted glass, and no new pieces of colour, should be added to it.

Mr. Philip Newman observed that he had severa samples of old glass with a pitting on the outside, but no indication of similar decay on the inside; which seemed to point to the fact that some atmospheric condition, which did not exist inside the building, was responsible for that condition rather than chemical disintegration or a change in the nature of the glass itself. A popular belief was held by those in favour of the external influence theory that a modern window had only to be kept long enough and it would present the same charming artistic effects as old fourteenth century windows. It would be unfortunate if that idea was done away with, because it would rob the donors of stained glass windows of much of the benefit which they thought they would confer on posterity.

Mr. Heaton, in reply to the Chairman's remarks with regard to "faking" of glass, said that in his paper he stated that credit must be given to mediæval glass painters for being ignorant of such practices; but nevertheless he was quite sure that, if it had occurred to them to do such things, they were quite as capable of carrying them out as people living at the present time. Without making a complete series of analyses of specimens, it was very difficult to answer the question why the older glass was freer from decay; that was the only way to answer the point satisfactorily. The Chairman had referred to the use of black glass for the flux. If the glass was coloured before the pigment was mixed with it, there was always a certain amount of opacity in it; whereas when the pigment was merely mixed with a colourless glass, in the finest lines the pigments tended

to get lost in the flux. He quite agreed with Mr. Powell, that Theophilus was not to be entirely relied upon. He should have hesitated to say so himself, but as Mr. Powell had led the way he had no hesitation in following his lead. He had always been told that spun glass, to the omission of which Mr. Powell referred, was referred to in the lost chapters of Theophilus; in fact, whenever anybody got into difficulties with Theophilus they always took refuge in the lost chapter, There was no doubt that spun glass was frequently found in early work; he has seen it himself in many cases. With regard to the question of the accuracy of the analyses, he quite agreed with Mr. Powell that analyses of glass were very often of doubtful utility, but the gentleman who made these exhibited was so skilled in undertaking complex silicate analyses that he was confident of their absolute accuracy. As regards these analyses however he would greatly appreciate it if any of his hearers would favour him by reading the description of the process employed given in the paper, and sending him any suggestion that occurred to them with a view to future work. He did not think the term, "opacity," was a correct expression to use in connection with mediæval glass; he would call it a slight opalescence, which, it seemed to him, was very readily explained by the presence of phosphorus in the glass. He had heard the statement made several times lately, that colour was not transmitted by old glass. It seemed reasonable to suppose that coloured glass ought to transmit coloured light whether it was old or new; but he had not made any experiments on the point. Mr. Whall had referred to the purification of the wood ashes. Wood ashes were not used now-a-days, in fact potash was never used in sheet glass. He did not know why that was so, and thought it was a great mistake. He entirely agreed with Mr. Whall's remarks with regard to the restoration of old glass, and, but for the length of his paper, would have referred to it there. M. Appert's work, which Mr. Hulme mentioned, was exceedingly interesting, but, so far as he had studied it, he did not entirely agree with the conclusions arrived at. It was, however, rather presumptuous to differ from M. Appert without thoroughly investigating the matter, which he shortly hoped to do. Mr. Reid had referred to the value of making microscopic sections showing the pitting in process of formation; and he hoped to be able to make some sections as soon as an opportunity presented itself. He agreed with Mr. Reid as to the possibility of pitting not always being due to the same cause. In the pitting, he (the author) showed the action was going on underneath a surface which was perfectly bright and free from corrosion, so he did not see how it could be a case of corrosion. In conclusion he would like to take the opportunity of asking glass painters to remember him when they had old glass passing through their hands and give him the opportunity of examining it.

On the motion of the CHAIRMAN, a hearty vote of thanks was accorded to Mr. Heaton for his interesting paper, and the meeting terminated.

NOTES ON INDIAN RAILWAY SYSTEMS.*

II.

The Bengal Nagpur Railway System.—Of this system of 1,990 odd miles of line, 1,697 miles are 5 ft. 6 in. gauge, the balance consisting of light railways of 2 ft. 6 in. gauge acting as feeders. This is one of the largest of the, as yet, unabsorbed private lines, the State guaranteeing the interest on the authorised capital outlay, at the rate of 4 per cent. per annum.

The Government has the right to determine the contract at the end of December, 1913, by giving 12 months previous notice, or, similarly, at the end of any succeeding tenth year. At the termination of the contract, the railway and all its belongings are to be handed over to the Government which will, on its part, repay the amount at par of the subscribed share capital of the company. It seems exceedingly probable that the Government will exercise its option on the first possible occasion, as the conditions of the guarantee have involved heavy losses to the State, a profit only having been secured four times since 1879. The revenue per mile of track is distinctly low. In 1904 (the best year recorded) this only amounted to 210 rupees. The line is certainly worked under economical conditions, as during the past six years the ratio of expenses to earnings has fluctuated between 40·56 and 54·63 per cent., the figure for 1904 being 48·97 per cent.

The permanent way is laid with 85 and 75 lb. flat-footed steel rails, with cast-iron pot sleepers, and transverse steel sleepers, a good stone ballast being used throughout. The ruling gradients vary between 1 in 125 and 1 in 200.

Financially, the year 1904 gave a net gain to the State of slightly over £3,000, as against a loss four times as great in the preceding year. The net earnings were 3·67 per cent. of the capital outlay.

The locomotive equipment consisted of 57 passenger engines and 174 goods engines. The total mileage run per day was 74 miles for passenger engines and 53 miles for goods engines. Per annum, the respective mileage is 27,225 and 19,276. The average ton mileage hauled per engine was 7,186,000 tons. The passenger rolling-stock consisted of 911 vehicles, the average daily mileage being 113.

The goods-vehicles numbered 7,148 of all sorts, their annual and daily mileages per vehicle being

* Abstracted from the Indian Government Railway Returns.

14,112 and 38 miles. The average profit earned per goods-vehicle mile was 15·65 (pies or 1,304 pence).

The Bengal and North-Western System.—Leaving certain of the broad gauge systems undescribed in order to analyse briefly the four chief metre gauge lines within the limits of the present article, the first of the latter is the Bengal and North-Western. Since 1882, when the first portions were sanctioned, some 870·80 miles have been opened for traffic, and 148 miles are under construction. By way of Government aid, land was provided free of charge. The various contracts between the railway company and the Government terminate by effluxion of time on December 31st, 1981, when the line and equipment becomes Government property on payment for rolling stock, moving machinery, stores, &c. The Government has, however, power to determine the contract on either December 31st, 1912, or of December 31st, 1932, on one year's previous notification of intention to purchase, at twenty-five times the average net earnings (up to but not exceeding 6 per cent. per annum on the share capital) for the five years preceding the purchase. The permanent way is laid with 50 lb. and 41¼ lb. steel rails, on sal sleepers; broken brick ballast is used. The sharpest curve has a radius of 900 feet, with a length of 2,000 feet. The ruling gradient is 1 in 300. The revenue per mile per week reached 168 rupees in 1904, the previous highest revenue being 161 rupees per week in 1903. The system is undoubtedly worked economically, as the ratio of expenses to earning in 1904 was 39·68. The net earnings were equal to 6·90 per cent. on the capital outlay. The traffic is handled by 225 locomotlves, of which only 20 are classed as for passenger service. The yearly mileage worked out as follows: 23,993 and 18,029 miles for passenger and goods services respectively, the daily mileage being 65 and 49. The ton mileage hauled per engine in 1904 was 4,279,000. Passenger vehicles numbered 942, the average mileage run by each being 140. Goods vehicles of all classes amounted to 5,711, the average daily mileage being 32. The average earnings per goods-vehicle mile were 21·76 pies (or 1,813 pence).

The Burma Railways System.—A particular feature in connection with this metre gauge system is that the Burma Railway Company was formed in 1896 to take over the existing State railways in Burma—which then had a length of 886 miles—and to extend these by the construction of other lines in particular—one from Mandalay to Kunlong. The terms of contract provide for a Government guarantee of interest at the rate of 2½ per cent. on the share capital. Land was also provided free of charge. The Government has the power to determine the contract at six months' notice if the company fails to perform its obligations, or in case of gross mismanagement, or if worked at a loss during three consecutive half-years. Alternately, the Government may also determine the contract at twelve months' notice on the 31st December, 1921, or at the end of any succeeding tenth year. In any event, if the contract is determined, the Government repays the share capital at its par value. After deducting working expenses, paying a fee for supervision, and interest on debenture and share capital, the balance of the annual profits is divisible in the proportion of four-fifths to the State and one-fifth to the company. During the last four years the company's share of the net earnings has varied between £25,800 and £39,500.

The working expenses have borne a fairly high ratio to gross earnings, the lowest value during the four years being 56·49 to 100 in 1904. The earnings per mile per week during 1904 were 216 rupees. The total mileage open at the end of that year was 1,340 miles, while 187 miles were under construction.

There is no special feature in the permanent way, 50 lb. rails being laid where the traffic is heavy, and 41¼ lb. rails where it is light. The sleepers are of teak and other indigenous timbers. Shingle and broken stone ballast are used. The ruling gradient on the main line is 1 in 200, but other severe gradients of 1 in 25, 1 in 60, 1 in 100, and 1 in 150, are to be found on the branch lines. The sharpest curves in the main line have (*a*) a radius of 573 feet with a length of 1,100 feet, and (*b*) a radius of 1,146 feet with a length of 2,900 feet. Sharper curves are to be found on the branch lines.

The traffic is worked by 236 eagines, 28 of which are classified as for passenger service. The average annual mileage of the passenger engines in 1904 was 30,228, and of the goods engines 17,612. The daily mileages worked out at 83 and 48 respectively. The passenger vehicles numbered 993. The average daily mileage per vehicle was 91. Goods-vehicles for dealing with the heavy traffic in agricultural produce amounted to 4,985. The daily mileage was 28, and the freight ton mileage was 41,000. The average profit per goods-vehicle mile was 9·5 pies (or practically 0·8 pence).

The Rajputana-Malwa Railway.—This long metre gauge line is classified in the Indian Government Railway Returns as a component part of the Bombay, Baroda and Central India Railway system. But the B.B. & C.I. Railway proper is a broad gauge line having a length of 504 miles, while the Rajputana-Malwa line has a length of 1,682 miles. The B.B. & C.I. Railway Company has worked this narrow gauge line since 1885, by an arrangement with the Government, whereby the working expenses of the entire system are pooled and divided between the component parts of the system in proportion to the gross earnings of each. The net earnings thus arrived at of the Rajputana-Malwa 3 feet 3⅜ inch line are paid in full to the Government. The company has the right to vary the fares within certain prescribed maxima and

The Rajputana-Malwa line itself dates back to 1870, when the Delhi-Rewari section of 51·25 miles in length was opened. The main line type of con-

struction at first adopted provided 36 and 40 lb. flat-footed iron rails on transverse deodar and creosoted pine sleepers. The 36 lb. rails gave place to 41½ lb. flat-footed steel rails, and these in turn to 50 lb. flat-footed steel rails, the half round pine sleepers being replaced by deodar sleepers. For ballast, stone, kunkur and sand are used, with a length of hard quartz some 30 miles in length. The sharpest curves have a radius of 600 feet; the ruling gradient is 1 in 150, with some short lengths of 1 in 40. The rolling-stock used consisted of 145 passenger engines, and 290 engines used for goods and mixed traffic. The respective average annual mileages are 22,617 and 14,911, or 62 and 41 per day. The passenger rolling-stock amounts to 1,684 vehicles of all classes, the average daily mileage of which is 106. The total number of vehicles used for goods traffic was 7,477, the average daily mileage being 39, while the annual freight-ton-mileage was 49,000. The average profit per goods vehicle mile was 14·66 pies (or 1·22 pence).

The Southern Mahratta Railway System.—The first contract between the Southern Mahratta Railway Company and the Government was signed in June, 1882, and by the end of 1884 the mileage open for traffic amounted to 214 miles. Within a further space of six years the system was completed, the total length of the Southern Mahratta Railway proper being 1,042. Subsidiary narrow gauge lines embraced by this system cover 601 miles of open line and 77 miles under construction. Government aid was afforded by a guaranteed rate of interest of 3½ per cent. in sterling on the approved share capital. Up to December 31st, 1890, an additional one-half per cent. was guaranteed. Under present working conditions three-fourths of the net receipts are paid to the Government, and one-fourth to the company. The contract is current for a period of 50 years, but the Government has the power to determine the contract after 25, 35, or 45 years (*i.e.* in 1907, 1917, or 1927) on one year's previous notice, or on six months if the company fails to carry out its obligations or is worked. Upon determination of the contract either by notice or by effluxion of time, the Government repays the share value of the company at par.

Financially the line is anything but a success. The earnings per mile of line per week were only 135 rupees in 1894, while the expenses were 63·29 per cent. of the gross earnings. The net earnings only worked out at 2·72 of the capital outlay, and the loss to the State amounted to nearly £135,000 sterling.

The permanent way presents no special features of interest. 44½ and 62 lb. flat-footed steel rails are used with steels and native wood sleepers. The ruling gradient is 1 in 100 except for three miles of 1 in 40.

The total number of locomotives in use on this line is 238, of which only 30 are definitely classed as allocated to passenger service. The average annual and daily goods engine mileages are 16,170 and 44, while the average annual and daily passenger engine mileages are 22,263 and 61. The number of passenger vehicles of all classes is 1,055, the average mileage run by each being 74. Goods-vehicles of all classes amounted to 4,861, the average daily mileage of each being 32. The average profit per goods vehicle mile is only 7·72 pies (or 0·64 pence).

RECENT DEVELOPMENTS IN ECONOMIC BOTANY.

In these days of progress and developments in all branches of science and manufactures, it is curious and interesting to note the numerous side lines and ramifications, not only amongst new vegetable products, but also very largely amongst those that in years gone by have had a steady existence for some one particular use, and these remarks apply equally to articles of food, medicine, or manufacture. Thus for instance, the trade in foreign and Colonial fruits was, until quite recently, confined chiefly to oranges, lemons and bananas, with occasionally a few mangoes, granadillas and Avocado pears.

The greatest development in any of these has been in the banana; the enormous increase in the shipments of which is familiar to everyone. There is no question about this fruit having taken hold of the popular taste, and those who observe this evidently think that the time has come when the banana should be considered in some other light than that of a favourite fruit, hence we have already seen that "Bananina," or banana meal, has been brought forward as a nutritious and easily digested article of food, and as an outcome of this another alimentary product is now announced, consisting of the pulp of the banana ground to flour and mixed with triturated cocoa (*Theobroma*) seeds, milk powder, and extract of malt. The process of manufacture consists in removing the peel of the mature banana fruit, and extracting from the peel its essential oil, drying the banana pulp and granulating and grinding it to powder, volatilising the essential oil from the peel, adding it to the banana flour and mixing with it a proportion of dried milk powder and pure extract of malt, and also the paste prepared from the cocoa seeds, and finally adding a sufficient quantity of sugar for flavouring. This composition is said to possess all the essential elements of a complete food in a concentrated form, namely, albuminous matters or proteids, fatty substances and hydrocarbons. Here, then, is a new outcome of the banana trade.

With regard to dried fruits it does not seem many years ago that raisins, currants, and a few prunes were the sum total of the culinary fruits that housewives had to fall back upon in the winter when fresh fruits were unobtainable, and these even were considered almost essentially Christmas fruits, but at the present time not only are these to be obtained at all times of the year, but in addition to them are the English grown bottled or canned gooseberries, plums and

other well known products of our fruit gardens which, though lacking much of the flavour of the freshly gathered fruits are by no means a bad substitute. A more recent addition, however, to our winter fruit supplies are the dried peaches, plums and pears, which are full of flavour and are excellent either stewed or in tarts; the only drawback is that they are so completely desiccated, that they require steeping in water for some 24 to 36 hours before using.

The advance made within the last 30 years in the use of cocoa as a beverage is very remarkable, and is, perhaps, due to a great extent to the persistent advertising of the leading firms engaged in its preparation. Whatever the cause, the result is satisfactory, seeing that in cocoa we have a wholesome and nutritious drink; but this is not all, for its applications in confectionery at the present time, in the form of chocolate creams and other similar delicacies, are so multifarious and extensive as to add considerably to the imports of this well known seed. Again, with the cocoa nut, or coker nut, as it is sometimes spelt to distinguish it from the *Theobroma*; many additional uses have been found in recent years both for the kernel of this nut, as well as for the oil in which it abounds. Though at one time the kernel was used almost exclusively in biscuit-making, its more recent developments have been in the direction of sweetmeats, for which it is now very largely applied. The oil, obtained by expression, was not many years since used almost exclusively in the candle and soap factories. Now, however, we find it used for culinary purposes as a substitute for lard or cooking butter under the names of "Nucoline" or "Vejsu" (a corruption of vegetable suet). In consequence of these extended uses, an increased demand has arisen for the oil, hence the rise in price of one of the materials in soap making upon which the makers base their advance in the price of soap itself.

Turning from food products to articles of manufacture, as might be expected in consequence of the widespread application of motor-power to road vehicles, and the development of electricity, we find the greatest amount of attention has been, and is still being given to rubber, both with regard to the question of supply as well as to that of quality, for notwithstanding that many new sources of rubber have of late years been brought to notice, none has been discovered that at all equals, or perhaps even approaches in quality and durability the old and well-known Para, which at the present time is worth about 5s. 6d. per lb. It has been stated that every motor car requires about £50 worth of rubber a year, and every motor 'bus £200 worth. Further, that the world's consumption now amounts to about 60,000 tons, and that by the end of the present year, at a rough estimate, the motor 'bus industry would consume two and a-half million pounds worth annually. To meet such a constantly increasing demand much attention has been given by public and private bodies to the extension of plantations in every country where it has been considered the particular plant would grow. This is the only way of meeting an ever-pressing emergency, and though the Para tree is a comparatively slow grower as compared with some of the other kinds, its cultivation should be systematically carried on where it is known that it will flourish.

With regard to vegetable fibres, in which field an enormous amount of energy has been shown in introducing new plants for trial, not so much for supplanting or substituting the old and well-tried flax, cotton, and hemp, but rather as additional to them, to meet the great and increasing demands for fibres for textile purposes, as well as for ropes and cordage, it may be well to note that out of the great number of fibrous plants that have been introduced during the last forty or fifty years, none can approach in the strength and durability of its fibres the plants already mentioned, namely, flax, cotton, and hemp. Jute, though it has become such an enormous article of import, and is now so extensively used in carpet and mat weaving, as well as for the cheaper kinds of cordage, lacks durability. Perhaps the most valuable of all the substitutes for the older vegetable fibres is rhea, or ramie, which, after a period of ups and downs, extending over more than half a century, during which time it has attracted much attention at the several international and trade exhibitions both at home and abroad, seems now to have really become established, and acknowledged in the manufacture of fabrics familiar to us by reason of attractive advertisements; and, though numerous experiments have been made with satisfactory results in weaving it into tapestries for curtains and furniture coverings, as well as for mixing with silk, or even alone as a substitute for silk, on account of its soft, glossy nature, its chief use at the present time seems to be for underclothing, for which it has been strongly recommended as possessing remarkable hygienic properties, absorbing and diffusing perspiration, and so preventing chill, besides preserving a normal temperature under circumstances which would otherwise produce exceptional heat. Its soft, silky character is said to make it peculiarly adaptable for delicate skins, and besides all this it is absolutely unshrinkable. For ladies' dress materials also, ramie fibre is now being made in all the fashionable colours. Moreover, a silk-like thread of extreme lustre, dyed in all the delicate tints now so general, has become very popular in art embroidery to which it lends itself as much for its ease in working as for its cheapness,—the source of this is without doubt the well-known ramie. Another entirely new application of this fibre is for the manufacture of incandescent gas mantles, for which purpose it is claimed to have many advantages over any substance hitherto used, the chief of which are greater strength, and in consequence the longer life of the mantle, greater illuminating power, and considerably less cost.

Whether all that has been said of the advantages of ramie for these new applications will be confirmed, experience alone will prove, but the writer of this article is able to attest, from his own knowledge, to the strength and durability of woven fabrics of nearly a quarter of a century back, so that with a fibre of such acknowledged capabilities it is much to be hoped that at last it has come to take a permanent lace in British commerce.

THE TREND OF TRADE.

The statistical Abstract for the principal and other foreign countries in each year from 1894 to 1903-4 has just been issued, and contains an immense amount of information respecting the trade of the world and its trend. The tables in the Abstract are in practically the same form as in previous issues, except that those showing the principal exports and imports of France, Germany, and the United States, have been considerably amplified and amended. Tables have also been added dealing with the import and export trade of Brazil, and with the production and consumption of cotton in the United States. The figures dealing with the shipping of the world show that the United Kingdom maintains its decisive supremacy, although proportionately other countries have improved their position. Thus, if we take the total tonnage of British sailing and steam vessels cleared from the ports of the United Kingdom and Germany respectively in the years 1894 and 1904, it will be found that the British tonnage cleared rose from 26,682,883 tons in 1894 to 31,893,297 tons in 1904, whereas the total German tonnage, taking the same years, rose from 5,104,348 tons to 8,750,219 tons. In 1894, the German tonnage cleared was considerably less than one-fifth of the British; in 1904 it was considerably more than one-fourth. These figures in both cases apply to vessels with cargoes only. In the case of the United States, there has been only a very slight proportional rise. In 1894 the American clearances with cargoes amounted to 3,000,747 tons, and in 1904 they had only increased to 3,308,430 tons.

The statistics of emigration show that in the case of nearly all European countries it continues to grow, although not always in proportion to the increase in population. This is most noticeable in Germany. Whilst births in that country have increased from 1,143,044 in 1894, to 1,264,534 in 1904, the total number of emigrants of German nationality, which in 1902 was 32,098, in 1905 was only 28,075. Most of the German emigrants go to the United States, and out of the total of 28,075, which left Germany in 1905, 26,005 went to America; Brazil, by the way, where there is a German colony, only getting 333. In proportion to population, the emigration from Italy is far larger than from any other country, and shows rapid increase in recent years. In 1898 the total emigration from that country was 139,187, las year it had increased to 479,349. The larger proportion still goes to the United States. In 1898 the number was only 56,703, whilst last year it had risen to 316,797. Next to the United States the larger number go to the Argentine, Uruguay, and Paraguay, the numbers rising from 36,793 to 88,840. The Italian emigration to Brazil has fallen from 38,659 to 30,079, but it is worthy of note that whilst much is said about the German colony in Brazil, Italian emigration to that country is enormously in excess of German. Emigration from Norway has risen from 6,207 in 1895, to 22,332 in 1904, nine-tenths of it going to the United States. The figures for Sweden are much the same, having risen from 9,678 in 1894 to 35,975 in 1903, and of this latter number, no less than 35,439 went to the United States, 325 of the remainder going to Canada. And so with Denmark, where the increase has been from 3,607 in 1895 to 9,034 in 1904, 8,405 going to the United States in the latter year.

The total value of imports and exports of merchandise into and from the respective countries shows, in nearly all cases, large expansion, but in none so large as in the United Kingdom. In 1894, the general imports were valued at £408,345,000; in 1904 they had risen to £551,039,000. Germany comes next with £210,250,000 in 1894, and £336,045,000 in 1904; the United States increasing from £136,457,000 to 206,476,000, but in general exports the United States takes the lead, having risen from £185,863,000 to £304,339,000, Germany coming next with an increase from £162,995,000 to £278,260,000. Perhaps the most striking increase is to be found in mining products. In 1880 the United Kingdom was far ahead of all other countries in the production of coal, the product for the year being 146,060,000 tons, as against 67,998,000 tons for the United States, and 46,974,000 tons for Germany. Last year the figures were very different. The United States produced nearly 90,000,000 tons of coal more than the United Kingdom, and Germany had increased her product to 121,298,000. It is much the same with iron ore as the following figures show:—

	1880.		1905.	
	Coal.	Iron.	Coal.	Iron.
	Tons.	Tons.	Tons.	Tons.
United States	67,998,000	7,120,000	328,102,000	44,054,000
Germany ...	46,974,000	7,239,000	121,298,000	23,444,000
United Kingdom	146,060,000	14,591,000	236,129,000	18,026,000

The cotton production of the United States has somewhat more than doubled since 1885, and its destination has altered considerably. In the earlier year 68·96 per cent. of the domestic product was exported; in 1905 only 61·55, and whilst in 1885 Great Britain took 1,209,917,044 lbs., against 234,493,533 lbs. taken by Germany, in 1905 the import to the United Kingdom had only increased to 1,983,626,888 lbs., whilst that to Germany had

risen to 1,005,839,498 lbs. France had again increased her import from 180,730,787 lbs. to 409,151,840 lbs., and Belgium had nearly doubled her import, whilst that of Italy rose from 29,563,180 lbs. to 267,367,731 lbs. On the other hand, the United States retained for domestic consumption in 1905 2,689,422,828 lbs., as against 2,689,432,828 lbs. in 1905.

GOLD MINING IN WESTERN AUSTRALIA.

Gold is still to be found in abundance in Western Australia, and constitutes the chief source of wealth of that State of the Commonwealth. Since 1891, when practically the first discovery was made, there has been a constantly increasing output, with the exception of 1900, 1904, and 1905, when the yield fell slightly below that of preceding years. Prior to 1898 the entire production amounted approximately to £4,800,000, but in that year work was begun in earnest, with the result that in the succeeding twelve months over £4,000,000 was taken out. In 1901 the sterling value of the gold mines was £6,720,000; in 1902, £7,609,000; in 1903, £8,336,000; in 1904, £8,129,000; in 1905, £7,819,000, and up to May 31, 1906, the yield amounted to £3,044,000. For purposes of comparison, and to show the position which Western Australia occupies in the world as a gold-producing State, the figures of 1904, showing the yield in ounces in Western Australia, the United States, and the Transvaal are given:—Western Australia, 1,983,000 ounces; United States, 4,090,000; and the Transvaal, 3,773,000 ounces. For several years the problem of a water supply for the gold fields was most difficult to solve, for in Western Australia, about 400 miles from Perth, the capital, there are no rivers, few natural supplies of surface water, and the rainfall is light. The vital importance of overcoming this difficulty was recognised by the State, and some idea of the magnitude of the undertaking may be formed by the cost of the construction, which amounted to over £3,000,000. In 1896, the approval of the Legislature was obtained to an expenditure for the provision of a supply of 5,000,000 gallons of water a day. The work was energetically pushed on, and brought to a successful completion in 1903. The supply, which is now regarded as adequate to the demands of the gold fields, is pumped three hundred and fifty-one miles. Fully 18,000 men are engaged in mining, and the wages paid are sufficiently high to induce first-class miners to remain permanently employed. In the gold fields the value of mining machinery in use amounts approximately to £4,000,000, and there have been erected about four thousand stamps. These figures show conclusively the splendid industry that has been built up, and everything now points to a continuance of the prosperous conditions.

ARTS AND CRAFTS.

Wall-papers.—To say that of recent years wall-papers have rather "gone to the wall," might perhaps lead to some misunderstanding. Still, the expression does suggest the kind of feeling which has come over people with regard to the trade. For some reason or other, wall-papers, or at any rate printed wall-papers, do not hold altogether the position they did. The satisfactoriness of the plain colours that can be got by means of distempering directly on to the walls has had, perhaps, something to do with this, and the practice of using painted or dyed canvas has, no doubt, further contributed to it. Still, the initial expense of painted canvas prevents it from being very largely used, and there is always to the ordinary man a certain nakedness about a distempered wall. At any rate, from no matter what cause, the fashion has of recent years very much changed, and in place of a filling paper in a bold design, coming straight up to the cornice or finished off with a more or less insignificant border, we see more often nowadays a plain wall or one bearing only a powdered or striped pattern, crowned by a frieze of at least a foot in depth and very important in design. Again, perfectly plain ingrain, or even lining, paper is quite often used now, to say nothing of brown paper. It may well be that this is a more or less unconscious protest against the sometimes very ugly lines which characterised a good deal of the wall-paper design of some years back.

Be that as it may, the idea seems to be abroad that there is something rather contemptible about a wall-paper; and so it comes to pass that at the present time the best efforts of the manufacturers are directed to producing effects of some other material. It does not appear to matter much what material is imitated so long as the thing is an imitation. The practice of counterfeiting tiles in bath-room papers is, of course, a very old one, and one, moreover, that explains itself; it is less apparent why people, especially in cities, should wish to pretend that their walls are covered with muslin curtains or with stuffs of various kinds. But this is apparently their desire, and all sorts of ingenious devices are employed to meet it. Some papers are printed with irregular vertical lines, giving them the appearance of rather uneven linen; others are on a slightly indented or impressed paper, which is crossed at intervals by chequer lines, and look, at a distance, like a rather coarse woollen or sacking material, on which, perhaps, a sprig or other small diaper-pattern is printed or woven at intervals. At times, something rather bolder is attempted, and, by a cunning device, a pattern is so printed that until one is near enough to touch it, it is difficult to believe that it is not in gesso or some other kind of relief. Again, advantage is taken of the rather uneven surface of some of the thicker kinds of paper to produce in ordinary distemper colour something which is to all appearances flock.

The patterns of any importance which are being brought out are, for the most part, early-Victorian chintz patterns adorned with large bunches of roses

or other natural flowers, and large damask patterns. The designs of these last are, in the main, copies or adaptations of old Italian silks, and are more often than not produced in a single colour on a satin-paper ground.

Cretonne and Wall-paper Design.—There is generally a certain similarity in the designs being used for wallpapers and cretonnes. Some people like the curtains and chaircovers, in their bedrooms at least, to be so much alike that they may be said to match—and, apart from this, there is always a demand for cretonnes "to go with" wallpapers and *vice versa.* It is true that the stripes which are still so popular in wall-papers have gone out of fashion for cretonnes, and dotted diaper patterns are now mainly used for casement curtains; so that, whilst in the case of wall-papers there is a large proportion of work being done which can hardly be dignified with the name of "design," matters are somewhat better with regard to cretonnes. Still, in both materials, there is a great deal being produced in the would-be naturalistic style of the mid-Victorian period. The proportion of pattern to ground is also very much the same.

Time was when most wall-papers were printed in "all-over" patterns, and the ground of cretonnes was as well covered as in the old-fashioned chintzes. We have long since changed all that, and at the present time the distinguishing characteristic of the wall-paper and cretonne designs is openness. A design (except it be a simple two-colour reversible) seems to have no chance of selling unless it shows plenty of ground space. No one, apparently, will look at designs of the old-fashioned all-over type, or at anything which, by the wildest stretch of imagination, could be called "crowded." Oddly enough, this demand for plenty of ground space seems to be more pronounced with regard to wall-paper and cretonne than to almost any other kind of material—and these happen both of them to be of such a quality that the ground is not really worth showing. There is no intrinsic beauty in the surface of cotton cloth or of the kind of paper usually used for wall decoration—and it is rather extraordinary that fashion should demand that so much of it should be shown. We can all understand and appreciate the beauty of plain surfaces in linen or silk damask, in pile velvet and other such fabrics. The demand for them in materials which are in themselves of no particular beauty, and might almost be called "makeshifts," is difficult for the ordinary mind to understand. An open pattern may be, and often is, graceful in a way peculiarly its own, and designs of this kind have much to commend them. They are, indeed sometimes, more reposeful than those which are fuller of detail; but, if they are to be really effective, they demand a ground which is in itself of a texture pleasant to look upon.

South African Arts and Crafts.—We are accustomed to look upon the colonies, and more especially the newer amongst them, as rather hopelessly outside the art movements of the day; and the idea of colonial arts and crafts is apt to bring a rather contemptuous smile to the lips of the English critic and connoisseur. This is not to be wondered at, for everyone must have seen some truly appalling colonial products labelled Art (with a very large "A"), and exhibited as something really remarkable, which would in England only pass muster at the most ordinary of bazaars. This state of things, moreover, is very evidently not a thing of the past, and it is not merely insular British pride which makes us still look askance at the efforts of Greater Britain towards art, whether pure or applied. It is, therefore, with a distinct feeling of astonishment, not to say relief, that we notice the signs of better things which are to be seen at the South African Products Exhibition. It is not that there is anything exhibited which is in itself very wonderful, or even perhaps, if judged by a high standard, very beautiful—but there are exhibits which show taste and appreciation of the beautiful, more especially in colour, which we should hardly have expected to find there.

First and foremost, from this point of view comes the little show of the Boer Home Industries and Aid Society. It consists almost entirely of tapestries and rugs woven in many cases from angora wool with a cotton or jute warp (which last is sometimes imported and sometimes home grown). Work of this kind, done as it is largely in schools quite recently founded, with a view to finding employment in their own homes for Boer women and girls, naturally compares with that done over here by the Home Arts Society. Of course, the scheme originated in this country and was started with English teachers, but the lines followed seem to have been sound and some persons connected with the undertaking, whether teachers or students it is of course impossible to say, appear to be gifted with a real sense of colour; for both in the copies of Oriental work and in the original designs the colour schemes are entirely satisfactory. This pleasing effect may be in part due to the creamy colour of the angora wool, but it is, in some degree at least, the result of deliberate choice. Altogether, this small exhibit from the Transvaal compares favourably in the matter of taste with similar stuffs produced under more or less the same sort of conditions in this country.

The Orange River Colony sends an exhibit of the work done in the normal schools at Bloemfontein and Bethlehem. The show consists entirely of lace and embroidery and is very small. There is nothing remarkable about the technique of the specimens exhibited, and here again, the guiding influence is plainly British, but the work is, some of it, quite tasteful, and the students evince a desire to do work which bears some impress of the country in which it was produced. The happiest piece of work is a bit of embroidery representing four very brilliantly coloured locusts which shows a rather daring sense of colour. The discovery that the name of the student responsible for it is partly Spanish and partly Dutch,

raises the question in how far her colour sense may be due to training and in how far to heredity.

Turning to native work; while the woodcarving is rude in the extreme and the beadwork will not bear comparison with that of the North American Indians, there is some very pretty and elaborate basketwork, notably from Natal and Rhodesia. If this kind of thing is produced in any quantity, it is rather surprising that we do not see more of it in the London shops.

GENERAL NOTES.

Paspalum Grass.—Mr. B. Harrison, of Burringbar Tweed River, New South Wales, has written an account of the *Paspalum Dilatatum*, a grass which has been found of great value to the stockowner and dairy farmer of Australia. It was introduced into Australia by the famous botanist, Baron Von Mueller and the late Mr. W. Farrer of the New South Wales Agricultural Department. In swampy country, which is the natural habitat of the grass, it grows well, and in the Tweed district it frequently attains the height of nine or ten feet. It is said to have proved very effectual in preventing and subduing the growth of noxious weeds. The reports of experience from various parts of Australia which have been printed are favourable.

Danish Shipping Profits.—For some time past the fact that the value of Danish imports is always much higher than the value of the exports, and that this difference has grown to over £5,000,000 annually, has caused some anxiety among Danish State economists; and some years ago the Government, under the belief that it would be of great interest to know, as far as possible, what profit the Danish shipping trade brought to the country, asked the shipowners to send in voluntarily the information required. They neglected to do so, and in March, 1904, a law was passed by the Rigsdag directing them to do so. This law came into force on January 1st, 1905, and in his report on the trade and shipping of Denmark for the year (Cd. 3283), Mr. Funel, Acting British Consul at Copenhagen, says that the particulars for the year are now available. The total amount of profit was £3,400,000, of which £2,430,000, or 71 per cent., were received on the trade between foreign countries, while £970,000, or 28 per cent., were received on the trade between Denmark and foreign countries. These £3,400,000 must, therefore, be supposed to be Denmark's gross profit on the transport of Danish and foreign goods between foreign ports and between Denmark and foreign ports. However, it must be supposed that over half of this sum remains abroad for covering various expenses. The greater part of the total is, of course, carried by the steamers, the share of the sailing ships being only 13 per cent.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday Evenings, at 8 o'clock:—

March 20.—"Smoke Prevention in Factories and Electric Supply Stations." By John B. C. Kershaw, F.I.C. Sir Joseph W. Swan, M.A., F.R.S., will preside.

Papers for meetings after Easter:—

"The Underground Water Supply of the Thames Basin." By Clayton Beadle.

"Hungarian Arts, Home Industries and Commerce." By Louis Felberman.

"Trypanosomiasis or Sleeping Sickness." By Herbert W. G. Macleod, M.D., B.Sc.

"The Cultivation of India Rubber." By Herbert Wright, Controller of the Government Experimental Station, Ceylon.

"Aerial Navigation." By Major B. F. S. Baden-Powell.

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

May 2.—"The Applicability to Indian Rivers of the Italian System of Dealing with Silt." By Sir Edward Charles Buck, K.C.S.I., LL.D., late Secretary to the Government of India, Revenue and Agricultural Department.

May 30.—"Irrigation Colonies in India." By Laurence Robertson, I.C.S., Under Secretary to the Government of India, Revenue Department.

Colonial Section.

Tuesday afternoons, at 4.30 o'clock:—

April 23.—"Social and Economic Conditions in Australia." By the Hon. John Winthrop Hackett, LL.D.

Applied Art Section.

Tuesday evenings, at 8 o'clock:—

March 19.—"Oils, Varnishes and Mediums used in the Painting of Pictures." By A. P. Laurie, M.A., Principal of the Heriot-Watt College, Edinburgh. Sir Luke Fildes, R.A., will preside.

April 16.—"Joinery and Furniture Making." By A. Romney Green. Halsey Ricardo will preside.

April 30.—"Lustre Pottery." By William Burton.

May 28.—"Sheffield Plate and Electro-plate." By Sherard Cowper-Coles.

Cantor Lectures.

Monday evenings, at 8 o'clock:—

Prof. Herbert Jackson, F.I.C., F.C.S., "Detergents and Bleaching Agents used in Laundry Work." Three Lectures.

April 15, 22, 29.

MEETINGS FOR THE ENSUING WEEK

MONDAY, MARCH 18...Surveyors, 12, Great George-street, S.W., 8 p.m. Discussion on Mr. A. J. Spencer's paper, "The Agricultural Holdings Act, 1906."

British Architects, 9, Conduit-street, W., 8 p.m. Sir Charles Nicholson and Mr. Hubert C. Corlette, "Modern Church Planning."

Medical, 11, Chandos-street, W., 8½ p.m.

Victoria Institute, 8, Adelphi-terrace, W.C., 4½ p.m. Rev. G. E. White, "Survival of Primitive Religion amongst the People of Asia Minor."

TUESDAY, MARCH 19...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Applied Art Section.) Dr. A. Laurie, "Oils, Varnishes, and Mediums used in the Painting of Pictures."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. W. Stirling, "The Visual Apparatus of Man and Animals." (Lecture VI.)

Faraday Society, in the Library of the Institution of Electrical Engineers, 92, Victoria-street, S.W., 8 p.m. 1. Messrs. H. Nutton and H. D. Law, "The Potential of Hydrogen liberated from Metallic Surfaces." 2. Messrs. F. M. G. Johnson and N. T. M. Wilsmore, "Electrode Potentials in Liquid Ammonia." 3. Mr. J. G. A. Rhodin, "The Impedance of Solutes in Solvents as manifested by Osmotic 'Pressure.'" 4. Dr. Slater Price, "The Electrololytic Deposition of Zinc, using Rotating Electrodes." (II)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. George Andrew Hobson, "The Victoria Falls Bridge."

Statistical, 9, Adelphi-terrace, Strand, W.C., 5 p.m. Mr. Noel A. Humphreys, "The Alleged Increase of Insanity."

Pathological, 20, Hanover-square, W., 8½ p.m.

Zoological, 3, Hanover-square, W., 8½ p.m.

Colonial Institute, Whitehall Rooms, Whitehall-place, S.W., 4½ p.m. Viscount Mountmorres, "The Commercial Possibilities of West Africa."

Horticultural, Vincent-square, Westminster, S.W., 3 p.m. The Hon. J. H. Turner, "Forestry in British Columbia."

WEDNESDAY, MARCH 20...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. John B. C. Kershaw, "Smoke Prevention in Factories and Electric Supply Stations."

Meteorological, 25, Great George-street, S.W., 7½ p.m. Major B. F. S. Baden-Powell, "The Exploration of the Air."

Microscopical, 20, Hanover-square, W., 8 p.m. 1. Mr. James Murray, "Some South African Tardigrada." 2. Exhibition of Specimens of British Mycetozoa by Mr. Alfred E. Hilton.

United Service Institution, Whitehall, S.W., 3 p.m. Colonel F. N. Maude, "The Factor of Mobility in Strategy."

British Archæological Association, 32, Sackville-street, W., 8 p.m.

Naval Architects (at the HOUSE OF THE SOCIETY OF ARTS), John-street, Adelphi, W.C., 12 a.m. Annual Meeting. Address by the Chairman, the Earl of Glasgow.

THURSDAY, MARCH 21...Naval Architects (at the HOUSE OF THE SOCIETY OF ARTS), John street, Adelphi, W.C., 12 a.m., Morning Meeting. 1. Mr. W. J. Luke, "Some Points of Interest in the Construction and Launch of the *Lusitania*." 2. Mr. S. J. P. Thearle, "The Evolution of the Modern Cargo Steamer." 3. Signor C. Piaggio, "Cranes for Shipbuilding Berths." 7½ p.m., Evening Meeting. 1. Mr. Archibald Denny, "Torsiometers as Applied to the Measurement of Power in Turbine and Reciprocating Engines." 2. Mr. J. Hamilton Gibson, "Torque of Propeller Shafting: some Conjectures, Investigations, and Results." 3. Mr. G. Simpson, "Propeller Struts."

Optical, 20, Hanover-square, W., 8 p.m. Mr. J. H. Sutcliffe, "One-Position Ophthalmometry."

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Messrs. E. A. Newell Arber and John Parkin, "The Origin of Angiosperm." 2. Exhibition of Water-colour Sketches of Alpine Flowers, by Miss Helen Ward, and Photographs of Transvaal Trees and Tree Scenery, by Mr. J. Burtt Davy.

Chemical, Burlington-house, W., 8½ p.m. 1. Mr. Emil Fischer, "The Synthesis of Polypeptides." 2. Mr. F. S. Kipping, "Organic Derivatives of Silicon." Part III. "Dl-benzylmethylethylpropylsilicane and Experiments on the Resolution of its Sulphonic Derivative." 3. Mr. H. J. H. Fenton, "The Reduction of Carbon-dioxide to form Aldehyde in Aqueous Solutions." 4. Mr. G. T. Moody, "The Mechanism of the Rusting of Iron." 5. Messrs. R. S. Morrell and A. E. Bellars, "Some Componnds of Guandine with Sugars." Part I.

Royal Institution, Albemarle-street, W., 3 p.m. Dr. C. W. Saleeby, "Biology and Progress." (Lecture II.)

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. Mr. J. A. Panton, "Rail Corrugation."

Historical, Lecture Hall, Field-court, Gray's-inn, W.C., 5 p.m.

Numismatic, 22, Albemarle-street, W., 6½ p.m.

FRIDAY, MARCH 22...Naval Architects (at the HOUSE OF THE SOCIETY OF ARTS), John-street, Adelphi, W.C. Annual Conference continued at 12 o'clock Morning Meeting:—1. Sir William H. White, "Experiments with Dr. Schlick's Gyroscopic Steadying Apparatus." 2. Mr. A. W. Johns, "Approximate Formulæ for Determining the Resistance of Ships." 3. Mr. J. G. Johnstone, "The Application of the Integraph to Ship Calculations." 7½ p.m. Evening Meeting:—1. Professor Vivian B. Lewes, "The Prevention of Fire at Sea." 2. Mr. Lyonel Clark, "Modern Floating Docks." 3. Professor Vivian B. Lewes, "Some Phases of the Fuel Question."

Royal Institution, Albemarle-street, W., 9 p.m. Professor J. J. Thomson, "Rays of Positive Electricity."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Mr. F. J. Kean, "A Point in Turbo-Alternator Design."

Botanic, Inner Circle, Regent's-park, N.W., 3¾ p.m.

Clinical, 20, Hanover-square, W., 8½ p.m.

Physical, Royal College of Science, South Kensington, S.W., 5 p.m.

SATURDAY, MARCH 23...Royal Institution, Albemarle-street, W., 3 p.m. Prof. J. J. Thomson, "Röntgen, Cathode, and Positive Rays." (Lecture VI.)

CORRECTION.—Page 456, column 2, line 15, the words "its northern" are misplaced. The sentence should read "district in Kent marked approximately by the lined area on the map, Fig. 1, its northern and eastern boundaries," &c.

Journal of the Society of Arts.

No. 2,835. VOL. LV.

FRIDAY, MARCH 22, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

APPLIED ART SECTION.

Tuesday evening, March 19; SIR LUKE FILDES, R.A., in the chair.

The paper read was "Oils, Varnishes and Mediums used in the Painting of Pictures," by A. P. LAURIE, M.A., D.Sc., Principal of the Heriot-Watt College, Edinburgh.

The paper and report of the discussion will be published in the number of the *Journal* for April 5.

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

Tuesday afternoon, March 5, 1907; SIR FRANK SWETTENHAM, K.C.M.G., in the chair.

The CHAIRMAN, in introducing the reader of the paper, said there was probably no one better able to deal with the wide subject covered by the title of the paper than Sir William Treacher. For a number of years he lived in Labuan, where he had an opportunity of studying Brunei; he was subsequently in the service of the British North Borneo Company, and was the first Governor of British North Borneo. Having completed his term of office there he went to the Malay States, and filled in succession the offices of British Resident in Selangor and in Perak; and, after sixteen years' service there, he became Resident General of the Federated Malay States. The audience would, therefore, realise that Sir William was eminently qualified to deal with the subject he had chosen, he felt sure that the lecturer would hold their attention, and he now asked him to read his paper.

The paper read was—

BRITISH MALAYA, WITH MORE ESPECIAL REFERENCE TO THE FEDERATED MALAY STATES.

By Sir WILLIAM HOOD TREACHER, K.C.M.G.
Late Resident-General of the Federated Malay States.

I was invited to read a paper "about the interesting but not too well known part of the Empire" with which my official career was connected, the reference being to the Federated Malay States, and as my official career since the year 1871 has brought me into more or less contact with the Crown Colony of Labuan, off the North-west coast of Borneo, the State of Sarawak, the territory of the British North Borneo Company, the Sulu Archipelago, the State of Brunei, the Federated Malay States, and the Crown Colony of the Straits Settlements, I thought it would not be amiss to assume for my paper the somewhat ambitious title of "British Malaya." I may add that Sir Frank Swettenham's great work, with the same title but with a different connotation, had not then been published.

The term "British Malaya" as a geographical and political expression I first heard employed by my distinguished chief, our present Chairman, Sir Frank Swettenham, at a farewell banquet to him on his relinquishing the post of Governor of the Straits Settlements and High Commissioner for the Federated Malay States, towards the close of 1903, when, after giving expression to his love for the Straits Settlements, in which and in the neighbouring Malay States the whole of his brilliant official career had been passed, he looked forward, in the somewhat distant future, to the possibility of a Malay Empire of the British Crown, comparable in some respects with the British Indian Empire, and comprising Burma, the Malay Peninsula, the Straits Settlements, and Northern Borneo. The countries I have enumerated comprise roughly an area of 351,600 square miles, with a population of

about 12½ million people. It will help you to comprehend the figures of area if I remind you that that of France is 207,218 square miles.

Probably most of you have read Mr. C. P. Lucas's first volume of his standard work, a model of exact compression, "A Historical Geography of the British Colonies," the second edition of which has recently been revised and brought up to date by Mr. R. E. Stubbs, and you will remember that after pointing out that Great Britain has possessed herself of outposts to the three great European Peninsulas—Spain (Gibraltar), Italy (Malta), Greece (Cyprus)—outposts which lead to the East, and are stations on the road to India and Australia, he reminds us that the three southern peninsulas of Asia—Arabia, India, and the Malay Peninsula — are magnified editions of those three European peninsulas, and that of these three southern projections of Asia and of some of the islands adjacent thereto, Great Britain has, in her course of expansion, also laid hold, for instance, in respect of Arabia, Aden, Perim, and Socotra, the whole of the Indian Peninsula and Ceylon, the Malay Peninsula, including Burma, Northern Borneo, Singapore, and many other islands in the Indian Ocean.

It is in regard to the last-mentioned peninsula and islands that I propose to ask your attention for a very brief period. I trust I am not transgressing any rule or custom of the Society, but I should like first to let imagination run round what might have been before dealing with what is and what is likely to be. What might have been, it seems to me, is, that our British Malay Empire might have included Burma, the Straits Settlements, the Malay Peninsula, Java, Sumatra, Borneo and other islands of the Malay Archipelago, with an aggregate area of over a million square miles, and a present population of about 49 millions. The British Indian Empire has an area of some 1¾ million square miles.

You will, perhaps, ask why? And I have only time to point out quite shortly that of the countries mentioned we do now actually either possess or control all the following, namely, Burma, the Straits Settlements, the larger portion of the Malay Peninsula, and Northern Borneo, while the others have been let slip only through our own supineness; for, as regards Java, the London East India Company in 1601, or thereabouts, established themselves in the island at Bantam, and at Batavia some 20 years later; and, though eventually driven out for a time by the Dutch, the island, probably one of the richest in the world, was captured by an expedition sent out by the East India Company, under Lord Minto, in 1811, and administered for five years by that great Empire builder and founder of Singapore, Sir Stamford Raffles. Unfortunately, under the Treaty of 1814, this magnificent island was restored to the Dutch in the year 1816.

Then, as to Sumatra, another remarkably fertile island, whence now comes some of the best wrap tobacco leaf, and also pepper, gold, and coal, we find that the same company established stations there in the early part of the seventeenth century, the principal of which was at Bencoolen, of which Sir Stamford Raffles was made Lieutenant-Governor in 1817; but again, most unfortunately, under the Treaty of 1824, the English possessions in the island were given up to the Dutch in exchange for Malacca. The British. however, retained certain rights in Achin, the native capital of the island, until so recently as 1871, when "England abandoned all her interests in Sumatra and ignored her Treaty responsibilities to the Sultan and people of Achin," as Sir Frank Swettenham puts it in the book I have already mentioned, "in return for Dutch possessions, of doubtful advantage, on the West Coast of Africa, with the result that we were immediately saddled with the Ashanti expedition, which cost a good many lives and £900,000, while the Dutch entered light-heartedly into an attack on Achin, which after 33 years of fighting and enormous sacrifices in blood and treasure, is not concluded yet."

The Dutch have since been left in peaceful occupation of their rich island colonies, so far as regards interference from other European nations, and admirable Colonial administrators they have eventually proved to be, as you may infer from the fact that the Island of Java, with an area of 50,554 square miles (almost exactly that of England without Wales), has a population of nearly thirty million against England's 30,800,000, and produces a sufficient supply of food for the consumption of its own population besides exporting coffee, sugar, and other products to Europe.

In 1861 an Indian civilian, Mr. J. W. B. Money, who had visited Java, was so impressed with the Dutch methods of administration that he published the results of his investigations in a two-volume book, entitled "Java, or How to Manage a Colony." In 1887 I was returning home from the East in a German liner, and, while passing by Sumatra, the captain, an

excellent specimen of a cultivated German, pointing to the distant land, remarked to me that the eventual destiny of the Dutch East Indian possessions was annexation to Germany.

Finally, as regards the Island of Borneo, after Australia and New Guinea the largest island in the world, and of which only about one-third is under the protection of Great Britain, the remaining two-thirds belonging to the Dutch. Leaving out of view the original connection of Portugal and Spain with this island, and coming to the period when those early colonising nations had, to all intents and purposes, been replaced by the British and the Dutch in the Malayan Archipelago, we find that Dutch and British dealings with Borneo commenced almost simultaneously, at the beginning of the seventeenth century, when the English opened somewhat unsuccessful stations on the east coast of the island, and later on at Banjermassin on the south, and Pontianak on the west coast, and it was not until 1818, under the terms of the treaty to which reference has already been made, that the British retired from Borneo, except the northern portion, in favour of the Dutch.

I may here say that I have not included the fertile Philippine Islands in my list, but I might have done so, and would remind you that in 1761, the East India Company's fleet, under Admiral Drake and Sir William Draper, captured Manila. The natives of the Philippines are of Malayan type.

I fear I may have wearied you by these references to the might have been, but it is good that we should sometimes have brought back to our recollections some of the works and deeds of our ancestors, whose enterprise amidst difficulties, many of which have been mitigated by the advance of science—the invention of steam, for instance—laid the foundation of our dominions and trade beyond the seas, and to whom we owe it that these little islands are the centre of an Empire, the greatest the world has yet seen, instead of an appendage of some more enterprising nation of the West.

From the point of view of ethnology the idea of a united British Malay Empire, comprising the countries I have referred to, is quite a sound one. In the first place all the countries named are peopled by Mongol or Mongoloid races — Burma by the Tibeto-Indo-Chinese branch of the Mongol family, the Malay Peninsula, Java, Borneo, and the Philippines by the oceanic Mongol division of that branch; so that the Burman may be called a Mongolian cousin of the Mongolian Malay. In regard to the last named group, we find that there existed, and in some cases still exist, an aboriginal race of Negritos, a division of the Ethiopic family (brachy-cephalic, or with heads approximately round horizontally), such for instance as the Semangs in the Malay Peninsula, the Kalangs in Java, and the Aetas of the Philippines. These were followed by Indonesians, dolichocephalic people, that is to say long-headed horizontally from back to front, a main branch of the Caucasic family, the highest family of the Hominidae, and to which we have the honour to belong. Existing examples of these are the Sakai of the Malay Peninsula, the Tenggerese of Java, the Land Dyaks of Sarawak, the Dusuns, Muruts and others of North Borneo, the Igorrotes of the Philippines. The Indonesians drove the earlier aborigines to the recesses of the interior, and were in turn bundled after them by the Mongoloid Proto—or savage Malays, such as the Sea Dyaks of Sarawak, the Jakuns of the Malay Peninsula, and the Sundanese of Java, who in turn gave way to the present real Mohammedan Malay who had become, in a measure, civilised in his Sumatran home. Of course, there has been a good deal of mixing between these races. As Mr. R. Shelford, to whom and to Mr. W. W. Skeat and Dr. Hose I have to express my deep obligations, has pointed out to me the Mongol has left his mark on all the people with whom he has come in contact, and if the contact is close enough and prolonged enough he either drives them out or fuses with them, and in one way or another swamps them. By the courtesy of Lady Murray, Messrs. Bampfylde, Leech. Knocker, and the British North Borneo Company, and others, I hope to be able to shew you slides illustrative of most of the races alluded to.

Ethnological questions are of entrancing interest, but cannot be put into a nutshell nor compressed into a ten minutes' conversation. In the appendix to this paper you will find the subject further elaborated in a paper kindly compiled for me from the works of Deniker and Keane and other well-known authorities by a friend, Mr. Walter W. Skeat, who also writes me as follows, and I commen what he says to your thoughts:—

"What I am most particularly keen about is t necessity for a racial survey, and I do feel that a practical point of this kind might be urged most strongly with great advantage in a lecture before the Society of Arts. The point is, I personally believe, not only material, but of vital importance for the maintenance

and development of the Empire. You in Borneo, if anywhere, know how a blood-feud can be avoided by an officer who knows the customs of the Dyak and how to handle them, where a new comer would, by some injudicious decision, in violation of the adat, set the whole country side in a blaze, though dozens of examples will occur if one thinks of them. Allowing for all exaggerations, there is at present a profound movement of native thought and opinion in all quarters of the world, a sort of native chauvinism, which, when it grows to its full height, will make unintelligent and unsympathetic government an exceedingly difficult matter."

It is time to return to actualities and to consider the Malayan countries which at the present day look to the King-Emperor, Edward VII. as their over-lord.

First as to Burma. That country is a province of the British Indian Empire, but then so, at one time, were the Straits Settlements. Its area is 238,738 square miles, or some 30,000 square miles more than the contents of the German Empire. Its population is put roughly at 19½ millions; its revenue at over 5 million pounds; and its Civil expenditure at 2½ million; its aggregate sea-borne trade is a good deal over 20 million pounds. It is mainly an agricultural country, and rice forms two-thirds in value of the gross total of exports, the next largest item being teak wood. I am sorry I cannot here deal at greater length with this province. A recent book, full and overflowing with facts, is Sir George Scott's "Burma, a Handbook of Practical, Commercial, and Political Information."

Now, I will ask you to travel with me to Northern Borneo and land in Sarawak. Here we strike an episode which yields a breath of the heroic ages—a theme worthy to have been sung by Homer. I can only attempt to bring back to your recollections the barest outlines, but they are based on the most up-to-date information, kindly forwarded me by my old friend Mr. Bampfylde, Political Agent for the Sarawak Government, in England.

In 1803, a son, James Brooke, was born in India, to an Indian official. The lad entered the Indian army, raised Brooke's Horse, and distinguished himself and was dangerously wounded in the Burma War of 1824-25; was invalided home; was wrecked on his return voyage to India; eventually resigned the service, purchased a brig and made an unsuccessful trading expedition to China; returned to England; sailed in his yacht the *Royalist* of 140 tons; reached Singapore; at the request of the Chamber of Commerce proceeded to Sarawak, a province of the kingdom of Brunei, on a mission of thanks to a Malay Raja who had rendered assistance to the shipwrecked crew of a British vessel, and became his friend; on a subsequent visit he took charge of the Raja's forces, put down a rebellion, prevailed with the Raja to spare the lives of the rebels, who became his life-long friends, while his influence with the Raja was augmented; a Chief attempted to poison him, failed and was disgraced, and the Raja—whose action was confirmed by his nephew, the Sultan of Brunei—handed over the Government to James Brooke, Raja of Sarawak, in September, 1841, Brooke then being aged 38.

His view of his position I will give in his own words, as recorded in his journal. After narrating the incidents relative to the transfer of the country, he says:—

"Difficulty followed upon difficulty; the dread of pecuniary failure, the doubt of receiving support or assistance; this and much more presents itself to my mind. But I have tied myself to the stake, I have heaped faggots around me, I stand upon a cask of gunpowder, and if others bring the torch I shall not shrink I feel within me the firm, unchangeable conviction of doing right which nothing can shake. I see the benefits I am conferring. The oppressed, the wretched, the outlawed have found in me their only protector. They now hope and trust; and they shall not be disappointed while I have life to uphold them. God has so far used me as a humble instrument of his hidden Providence; and whatever be the result, whatever my fate, I know the example will never be thrown away."

Single-handed, with but comparatively a small private capital, the whole of which he sank in the country, with no support from a Government or a Chartered Company at his back, he had to organise administration, suppress piracy, head-hunting and intertribal wars and break the power of tyrannical and oppressive Malay and Dyak chiefs.

In the suppression of piracy he had the whole-hearted sympathy and assistance of the late gallant Admiral Sir Henry Keppel, who fortunately happened to be in those waters at that time, but the final blow to piracy was not given till 1862, when the then Raja Muda (Capt. Brooke Brooke) met and utterly destroyed, off Bintulu, a large piratical fleet, on its return from a cruise round Borneo.

The Province originally acquired was of small area, some 3,000 square miles, with a coast line of 60 miles, but in 1853 a large extension was gained by the cession by the Sultan of Brunei of the country up to and

including the Rejang River, thus bringing the warlike Sea-Dyaks under Brooke's government.

The task of subduing these warrior tribes into order was assigned to a young ex-naval officer, of the age of 24 years, now the present Raja, Sir Charles Brooke, of Sarawak, and by a rare combination of sympathetic personality and love of hard fighting, the task was in due time successfully accomplished, and the affection of the Sea-Dyaks secured by this young nephew of the Raja.

In carrying out his noble mission the old Raja was sorely tried in many ways apart from financial considerations. I will give two instances.

It had been Brooke's hope that the British Government would take his country under its protection, and possibly eventually add it to the Empire, and his disgust and disappointment may be imagined when in 1853 his proceedings in connection with his expeditions against the pirates were violently attacked in the House of Commons, and on the motion of Mr. Hume, a Royal Commission of Enquiry was appointed—even though the Commission's decision was in his favour. The Little Englanders of the time prevailed, and the opportunity of annexing Sarawak was lost. Then, again, before his advent, Chinese from Dutch Borneo had made many attempts to work the rich gold and antimony deposits in upper Sarawak, but suffered severely at the hands of the Malays; with the security which followed the introduction of good government by the Raja, the Chinese increased and multiplied and waxed fat and insolent, and rose against their benefactor in 1857, seized and destroyed the capital, Kuching, many Europeans losing their lives, but eventually were either nearly all killed or driven over the border by young Brooke and his Sea-Dyaks. This delayed progress for many years and crippled the Raja's capital resources. However, the late Baroness Burdett-Coutts, always his devoted friend, stepped in with some financial assistance; later on she presented the Sarawak Government with a steamer, and further showed her interest in the State by inaugurating experimental farms and rice husking mills.

Sir James Brooke—he had been made a K.C.B. in 1848—spent the closing years of his life in England, on a property presented to him by the public, where he died in 1868.

In 1863 the British Government had recognised Sarawak's independence of Brunei, but it was not until 1888 that it was formally recognised as an independent State under the protection of Great Britain, such protection conferring no right to interfere with the internal administration of the State, its foreign relations alone being placed under British control.

I have already made allusion to Sir James Brooke's successor, his nephew, the present Sir Charles Brooke, G.C.M.G., who, faithfully carrying out and developing the ideas of his uncle, now rules as an independent sovereign over a contented and prosperous Sarawak, which, from a territory of 3,000 square miles in extent, has grown, by absorption from Brunei—which, as you will see by the map, it completely surrounds—into a State of 50,000 square miles, with a population of over 400,000 (including 45,000 Chinese), the capital, Kuching, with a population of 28,000, being probably the largest town in the whole island of Borneo. The idea of the Government may be briefly put as—government of the natives by natives and for the benefit of the natives, under white control and direction.

The revenue of Sarawak was, in 1870, 122,842 dols., and its expenditure 126,160 dols.; in 1905 these figures had grown respectively to 1,353,477 dols. and 1,240,523 dols. The aggregate value of its trade in 1864 was 1,172,958 dols., while by 1905 it had increased to 13,422,267 dols. The chief exports are pepper and sago, and in these two products it takes the lead of all countries in the world. It is a large exporter of jungle products, such as inda-rubber, gutta percha, rattans, damar, bird's nests, and timber. Gold, antimony, and coal are also among its exports, the gold being most profitably worked by that wealthy body, The Borneo Company, Ltd., which followed Raja Brooke's fortunes from the first, and has extended its ramifications over so many parts of the East.

As will be shewn in the sequel, Brooke's arrival in Sarawak paved the way for the British occupation of the whole of Northern Borneo, so that he was, in fact, the founder—not only of his own dynasty—but of the Borneo Protectorates of Great Britain and the Crown Colony of Labuan.

His friendship with the Sarawak Raja (whose full name and title was Raja Muda Hassim, heir-apparent to the Sultan of Brunei) and his efforts to repress piracy, which had been a source of advantage, and profit to some of the Brunei Ministers of State, involved Hassim in troubles with his own people—resulting in many of his adherents being killed,

while Hassim himself committed suicide. Whereupon a British squadron took the town of Brunei, and the small uninhabited island of Labuan, with an area of a little over 30 square miles (about the same size as Hongkong) situated some 30 miles from Brunei, was formally ceded to Great Britain, in 1846, Sir James Brooke being appointed its Governor and British Commissioner and Consul-General in Borneo. The little island never fulfilled the expectations formed of it as a trade emporium and shipping centre, nor have the attempts of several companies to work its valuable coal mines hitherto met with substantial financial success. Until 1869 it depended upon grants from the Imperial exchequer, and for a few years after 1889 the administration was entrusted to the British North Borneo Company, but in 1905 that arrangement ceased, and Labuan is now part of the colony of the Straits Settlements. It is interesting to note that so far back as 1774 the East India Company, having been expelled by Sulu pirates from the island of Balambangan, to the North, had established a short-lived trading station at Labuan and also at Brunei.

I have already told you that Sarawak has gradually surrounded and overlapped its parent, the State of Brunei, from the south. The Brunei territories to the north were alienated to a British company under circumstances which I shall be able to explain to you in only a very cursory manner, and the State which, in the days of active trade relations with China, had ruled over the whole of the north of the great Island of Borneo, is now reduced to an area of some 4,000 square miles, the capital which Pigafetta, in 1521, described as containing a population of 25,000 families, is reduced to one of 10,000 or 12,000 souls. The magnificence of the court so eloquently pictured by the same writer has dwindled away and Brunei, shorn of all its provinces, became, in 1905, a British Protectorate, the Sultan taking his orders from a British Resident. This result was secured by the diplomatic ability of Mr. Douglas Campbell, one of the British Residents in the Malay Peninsula.

The most striking feature of the town is that the houses are built on piles in a very beautiful river, and with some stretch of imagination it has been styled the "Venice of the East," canoes taking the place of the Venetian gondolas.

The growth of the British North Borneo Company's territory arose in this wise:—

In 1865, a syndicate in the United States obtained certain concessions from the Sultan of Brunei, but an American Commodore, who several years after was sent to report to his Government what was going on, informed me that he could find no American subjects in the country, white or black. In 1872 I took short leave from Labuan and proceeded to Sandakan on the east coast of Borneo, now the capital of British North Borneo, with a population of 8,000 or 9,000. Here I found an episode of enterprise which illustrates how the Empire is built up by the individual enterprise of her sons. There was settled Mr. W. Clarke Cowie, now the London managing director of the North Borneo Company, flying the British flag in a little stockaded kampong, surrounded by piratically inclined Sulus, Illanuns, Bajows, &c. It was only a year or two afterwards that a boat from the Austrian frigate, *Friedrich*, was captured by the natives of the neighbourhood and the heads of two of the crew taken round the villages in triumph.

Mr. Cowie had travelled all the way from England in a little 14 ton steamer, and was, at the time I mention, engaged in the fairly lucrative business of running the Spanish blockade of the Sulu Islands, having become on very intimate terms with the Sultan of Sulu, who shared in the profits. I should mention here that the Sulu Sultans laid claim to certain portions of Northern Borneo by alleged cession from a former Sultan of Brunei, and through the Sulus the Spanish Government also claimed, and to finish this part of the subject, I may add that in 1879 I was sent by our Government, in a man-of-war, to Sulu and other ports of North Borneo to publish an official protest against the Spanish pretensions, and later on a protocol was signed whereby Spain renounced all claims to any portions of Northern Borneo and the adjacent islands.

The next important step was the appearance on the scene, in 1877, of Mr. (now Sir) Alfred Dent, the founder of the North Borneo Company, which was incorporated by Royal Charter in November, 1881, after some opposition from the Dutch. The American Syndicate was bought out, arrangements were entered into with the Sultan of Brunei for the cession of 20,000 square miles of territory towards the north, and with Mr. Cowie's assistance negotiations were successfully concluded with the Sultan of Sulu for the cession to Mr. Dent and his friends of all his Highness's rights of any kind in Borneo.

North Borneo has steadily advanced nearer

and nearer to Brunei from the north, as Sarawak has from the south, and its area is now computed at 31,000 square miles. It is a country of great natural fertility in regard to both climate and soil; the cultivation of first class wrap tobacco has been successfully carried on for several years past—I am told the new Darvel Bay Plantation Company last year grew a crop at a cost of about £50,000, which realised over £90,000—and large areas are now being planted with Para rubber, estates which have been opened only for a few years showing an extraordinary and most encouraging growth of that tree.

In regard to mineral wealth, manganese is being worked by a London company in Marudu Bay, and the deposits are estimated to contain some millions of tons. Considerable hopes are, I believe, entertained from the occurrence of very large deposits of iron ore reported to be of excellent quality. Coal occurs in many parts of the territory, and is being worked in Cowie Harbour, while a small area of smokeless coal is reported at Jambongau on the east coast. The alluvial gold has not yet been successfully exploited.

A peculiarity of Sarawak is that it is practically roadless and railway-less, its numerous rivers and steamers sufficing for means of communication. North Borneo, while similarly roadless, possesses a completed railway of 127 miles on the west coast, and is meditating two other lines, one between the Bays of Sandakan and Marudu, 100 miles, and the other an extension of the Tenom line to Cowie Harbour, 160 miles. When we come to the Malay Peninsula we shall find roads and railways and little river traffic.

The population of North Borneo is given as 160,000, but no accurate census of all the interior tribes has yet been possible. The Chinese number some 12,000 or 13,000. The revenue has advanced from £13,220 in 1883 to £113,204 in 1905. The total trade for 1905 is returned as 7,433,757 dols.

I am anxious to get on to the Federated Malay States, which are the main subject of this paper and as the Crown Colony of the Straits Settlements, probably under the name of Singapore, its chief port, is very likely more or less known to you as one of the greatest trading centres in the world, the gateway to the Far East, one of the chain of fortified coaling stations for our fleets, the meeting place for the annual conferences of the Admirals of the East India and China and Australian squadrons, and as recently the scene of Lord St. Aldwyn's labours as umpire in the matter of the taking over by the Colonial Government from an enterprising company of the docks and wharves which are so important and vital a part of the colony's equipment, I will not detain you longer than to put before you a few statistics showing how important and valuable a component part of the Malay Empire the Straits Settlements are.

The area of the colony is 1,542 square miles, and its population, at the census taken in 1901, was 572,249; Europeans numbering about 5,000; Malays, 215,000; and Chinese, 280,000.

May I, in passing, ask you to reflect that the King-Emperor, Edward VII., in addition to ruling over more Mohammedans than any other Sovereign, has in his dominions the largest number of Chinese inhabitants outside of China? In what I have ventured to style His Majesty's Malay Empire alone, there are 715,000 Chinese (Federated Malay States, 300,000; Straits Settlements, 280,000; Burma, 65,000; Borneo, 70,115), whilst the Chinese population of Hong-kong and Kowloon is numbered at 350,000, and that of Wei-hai-Wei at 150,000. These places alone give a total approaching 1¼ million of Chinese, and yet we are making a fuss over some 40 or 50 thousand Chinese miners in South Africa!

For the year 1905 the revenue and expenditure of the colony, exclusive of its municipalities, were respectively 11,657,424 dols. and 10,980,391 dols. Its aggregate trade for the same year was 609,208,773 dols.

Perhaps I ought to tell you that the Straits Settlements are in the main a clearing house for the products of the East and the West, a great coaling and refitting station, and that they hold what are, I suppose, the largest tin-smelting works that exist anywhere, in them being treated the greater portion of the tin ore from the Malay Peninsula.

Singapore possesses a magnificent harbour, the capabilities of which are being extended by the judicious expenditure of colonial funds. Penang harbour also affords good accommodation, and its facilities are likewise being enhanced.

The colony's principal agricultural products are sugar, cocoanuts, and rubber, and pineapples which are commonly to be seen canned for sale in shops here. At Christmas Island, very large deposits of phosphate are being worked by a British company.

The genius of Sir Stamford Raffles secured Singapore for England by cession from the Government of Johore in 1819. Penang was

acquired from the Sultan of Kedah, by the East India Company, in 1785, and the possession of Malacca was finally confirmed to us by the Treaty of 1824.

The Straits Settlements were separated from India and became a Crown Colony in 1867.

I have recently received the third edition of an excellent hand-book, giving information in regard to the Straits Settlements and the Federated Malay States, compiled by Mr. H. Conway Belfield, British Resident of Selangor, and to that work I would refer those who are desirous of further information in a concise form.

Great Britain having obtained a *pied-à-terre* in the Islands of Penang and Singapore, it followed naturally, as it almost invariably does, that she should extend her influence over the neighbouring mainland.

All the southern portion of the Malay Peninsula is controlled by the British, viz., the States of Perak, Selangor, Negri Sembilan and Pahang, now known as the Federated Malay States, aggregating over 26,000 square miles, and in addition the State of Johore nearly 10,000 square miles. Over the rest of the peninsula, with the exception of Trengganu, we have allowed the Siamese to extend their active control notwithstanding that in 1786 the then ruler of Kedah had ceded to us Penang and Province Wellesley on condition of being protected against the encroachments of Siam, and that by the British-Siamese Treaty of Bangkok, 1826, both the contracting parties had agreed not to interfere in the States of Kelantan and Trengganu. The Siamese Government, with the object-lesson before them of the extremely successful results of British regulation of the Peninsular States, has decided to follow, more or less closely, our policy, and amongst other things has appointed Englishmen as Resident and Assistant Resident in Kelantan and has, so far without success, attempted the same action in Trengganu, the Sultan of which State appears to be coy in regard to the flattering attentions from both the Siamese and the British, and to prefer complete independence.

Again following our example, the Siamese have now under consideration the joining up of their Eastern States by a railway to be constructed departmentally by their own Government Railway Department, which is controlled by an official of German nationality. This awakening of Siam in these parts, on European lines, may be watched with interest; and if they adhere to European ideals, and continue, as is now the case, to utilise the services of Europeans, as advisers in regard to finance, railways, forest conservation, law, and so forth, it is possible a fair success may be achieved.

To finish with the matter of Siamese intervention in the peninsula, I may add that by the Anglo-French agreement of 1896, Siam Proper was recognised as a buffer State between British Burma and French Indo-China, and was neutralised, independent action being retained by the British and French reespectively in regard to Siamese dependencies West (British) and East (French) of the neutralised zone. By a subsequent agreement, however, in 1904, both Powers disclaimed any intention of annexing the Siamese territory in their respective spheres of interest.

In regard to Johore I need only say a few words. It is governed independently by the Sultan, who, as well as his late father, the enlightened Abu Bakar, has paid frequent visits to England. Since 1885 its foreign relations have been placed under the control of Great Britain, which has the option, hitherto unexercised, of appointing a British agent in the State. Its propinquity to the flourishing cosmopolitan British Colony of Singapore, and the frequent intercourse thus resulting between the Malay Sultan and the British Governor, has doubtless had a beneficial effect on the form of government, and the same proximity has enabled the ruler to obtain an easy revenue, mainly from opium, spirits, and gambling farms, and export duties on the gambier and pepper cultivated by the Chinese from the colony. The nature of the country is similar to that of the Federated Malay States, but it is at present practically roadless and awaiting development, to which an impetus will be given by the railway which is being constructed out of the surplus revenues and by the railway department of the Federated Malay States. Europeans are entering the country to exploit it for rubber cultivation and tin mining. The present revenue of the State is said to amount to about 1,250,000 dols. a year.

The Federated Malay States may be regarded as quite one of the most successful experiments, presided over by the Colonial Office, in establishing a government with European ideals amongst a tropical people in a country given over to anarchy and confusion, where might was right and the common people held their lives and property at the caprice of their chiefs.

Before we actively took in hand the Malay Peninsula (I will not delay for reference to abortive attempts by the East India Company), the ubiquitous Chinese had for several years been working the rich deposits of tin in Perak and other of the States, and at the time I am referring to they numbered about 20,000 in Perak alone. The two main reasons for our interference were internal strife amongst the Malays, questions of succession to the throne, and so forth, and bloody disputes between rival clans of the Chinese who were working the tin, resulting in piracy along the coast, interference with trade, and excitement amongst the colonial Chinese partisans of the miners in Malaya. The instructions to the Governor of the Straits Settlements precluded his effective interference in the affairs of the Peninsula, but towards the end of 1873 a new Governor, Major-General Sir Andrew Clarke, was appointed, with orders to enquire and report what steps it might be possible to take to remedy matters, as to the advisability of appointing British resident officers in the States.

With Sir Andrew Clarke, a many-sided and able man, short was the inquiry and quick the action; without waiting for final instructions from the Colonial Office he, within some two months of his assumption of office, convened a meeting of the Perak Chiefs at the Island of Pangkor, off the mouth of the Perak River, and on the 20th January, 1874, was signed and sealed the Pangkor Treaty, giving birth to the germ of the residential system in the Peninsula, for by this document the Sultan and Chiefs of Perak agreed to the appointment of a British Resident and Assistant Resident in their country, whose advice was to be followed in all questions other than those touching Malay religion and customs, while the collection and control of all revenues and the general administration of the country would be regulated by their advice. Sir Andrew Clarke then attacked the questions affecting the other States on the western side of the Peninsula, and in November, 1874, the appointment of five officers to be respectively Resident and Assistant Resident of Perak, Resident and Assistant Resident of Selangor, and Assistant Resident of Sungei Ujong were gazetted. At the historic meeting at Pangkor there were present the Governor, Sir Andrew Clarke, with Mr. Braddell, Attorney-General, Major McNair, Mr. Skinner, Captain Dunlop, Mr. (now Sir) Frank Swettenham, and Captain Speedy, accompanied by the Mentri and the Temengong; Mr. Pickering, with Raja Abdullah, Raja Dris, Datu Sagor, and Raja Mahkota; Sultan Ismail was absent. Mr. James W. Birch, the Colonial Secretary of the Straits Settlements, was appointed to be first Resident of Perak. He had come from Ceylon, and was a man of extraordinary energy, which has descended to his son, Mr. E. W. Birch, C.M.G., now holding the position first occupied by his father, but under very different conditions. Mr. Birch unfortunately was entirely ignorant of Malay language, customs, habits, and prejudices, and his task was an exceedingly difficult one. I would ask any of you gentlemen here living at home at ease, what would be your feelings if you were suddenly called upon to undertake the administration of a roadless country and the collection and control of all its revenues, where hardly the rudiments of government existed, where there were rival claimants to the throne, where slavery for debt was an institution, and the language, customs, habits and prejudices of the people were unknown to you, and you possessed no force to back you up beyond a small bodyguard of native police?

Time fails now to recount all the antecedent circumstances, but in November, 1875, Mr. Birch was assassinated while in his bath-house on the Perak River. As Sir Frank Swettenham narrates: "Mr. Birch did not die in vain; his death freed the country from an abominable thraldom, and was indirectly the means of bringing independence, justice and comfort to tens of thousands of sorely oppressed people," for there followed on the crime what is known as the Perak War, with the result that Sultan Abdullah was dethroned and exiled and the way made clear for the eventual accession to the throne of the present enlightened Sultan Idris, G.C.M.G.

Mr. Birch was succeeded by Mr. Davidson, transferred from his post as Resident in Selangor. He resigned in less than a year, when Sir Hugh Low was selected for the important post. Mr. Low, as he then was, had started life in the East under the auspices of the great Sir James Brooke, and had early imbibed his love for the Malays and his admirable method of dealing with them, and possessed what had been lacking in the first Resident, a sound knowledge of the Malay language, customs, habits and prejudices, acquired during many years' service in Labuan, where he had close intercourse with the Malays of Brunei and the northern portion of Borneo, and the Chinese

traders. After good, honest, and brilliant work in Borneo and the Malay Peninsula he retired from official service in 1889, leaving a happy, contented, and rapidly progressing Perak in the hands of his successor, our Chairman, who by that time was British Resident of Selangor, and had been identified from the very first with all the negotiations for the introduction of the residential system, *quorum magna pars fuit.*

The remaining State, of the present Federation, Pahang, the largest in area of all—being of greater area than Perak, Selangor, and Negri Sembilan together—is situated on the east coast of the peninsula. In 1887 the Sultan entered into an agreement with Governor Sir Frederick Weld, and accepted a British agent, Mr. Hugh Clifford, now Colonial Secretary, Ceylon, who in the following year, as the sequel to the murder of a Chinese British subject, was replaced by a full Resident, Sir John Rodger, at present Governor of the Gold Coast, after negotiations conducted by Governor Sir Cecil Clementi Smith, who first as Colonial Secretary, and subsequently as Governor of the Straits Settlements, had always taken a keen, able and sympathetic interest in Native States affairs, and in their material development. The Sultan has remained loyal, at any rate superficially, but in 1891 and 1894 a local chief rose up against the Government; the disturbances, however, were quelled by Indian police from the other States and the Straits Settlements without the aid of British troops.

In 1905 an important further advance was made by the Sultans of the different States entering into an arrangement, as the result of negotiations initiated under instructions from Mr. Chamberlain, then Secretary of State for the Colonies, and ably carried through by Sir Frank Swettenham, whereby all the States were federated and a Resident-General appointed to supervise the Residents, and to be the medium of communication with the Governor at Singapore, who was thenceforward styled High Commissioner for the Federated Malay States.

I should like you to fix your attention on the fact that two main points were kept in view in this arrangement, first, that the King's Governor at Singapore should, as High Commissioner, have the power of general supervision and control. I lay stress on this because it bears upon the idea which runs through my paper of a possible British Malay Empire, the centre of which would be the great trade emporium of Singapore, and in furtherance of this view we have now an official who combines the offices of Governor of the Straits Settlements (which include Singapore, Malacca, Penang, Province Wellesley, the Dindings, all in the neighbourhood of the Malay Peninsula, and the Cocos and Christmas Islands in the Indian Ocean, and Labuan, off North Borneo) and of High Commissioner for the Federated Malay States of the Peninsula, and for Brunei, in Borneo, and of Consul-General for British North Borneo, and for the State of Sarawak.

The second point was that while no one of the Sultans can interfere with the affairs of a State other than his own, they agreed that they would give one another such assistance in men, money, or other respects, as the British Government may from time to time advise. I may add a third point, that they undertook, should the British Government become involved in war, to send at their joint cost a body of armed and trained Indian troops for service in the Straits Settlements; this is the origin of the fine body of men, numbering about nine hundred, known as the Malay States Guides, composed of Sikhs and Pathans recruited from India, many of them medalled soldiers of the Indian army, officered by officers from the British or Indian regular army, under the command of Lieut.-Colonel Walker, C.M.G.

Federation came into actual being on the 1st July, 1896, and from that date the Civil Service began to be recruited, no longer from nominated officers, who had so quietly and efficiently done such successful work and insured such successful results, but, like the services of Ceylon, Hong-kong, and Straits Settlements, from officers selected by a competitive examination held in London in combination with the examination for the Home and Indian Civil Services.

In the old days a man was set down in a district, and was told to rely on his personal influence with the natives to introduce order where chaos had reigned, and he was allowed a pretty free hand; with the growth of the country's prosperity and the concomitant increase in the numbers of the Civil Service, a mass of Government regulations necessarily came into being, and less individual scope can now be allowed to the individual officer.

As to the secret of our success in governing Malays, not only in the Malay Peninsula, but also in Sarawak and elsewhere, I will, as time is short, mention only two points:—First

entire sympathy on the part of European officials with the natives, an earnest effort to enter into their thoughts and feelings, which can only be secured by acquiring a knowledge of their language, and by mixing with them in a friendly and not too superior spirit, and above all by being freely accessible to them in one's house or in one's office, whether those who seek an interview are rich or poor, aristocratic or plebian; by encouraging those of their peculiar customs and laws which have an element of good in them or are harmless, discouraging those that are radically bad, degrading or cruel, and by refraining from the endeavour to reform the natives out of all recognition of their natural selves.

The second point, one which applies especially to the Peninsula, where the extraordinary deposits of tin have given us the wherewithal, is a generous but judicious expenditure on public works, roads, and railways. In illustration of this point I may quote from a report on the Federated Malay States made to the Parliament of the Commonwealth of Australia by Senator the Hon. Staniforth Smith. He says, referring to the estimated expenditure of the States for 1906:—

"It is worthy of notice that in Public Works and Maintenance £1,346,528 are to be spent—a sum equal to nearly 60 per cent. of the total revenue. So large a percentage of revenue spent in public works is probably unequalled in any part of the world."

Here I may say that these young States have built over 400 miles of excellently constructed metre-gauge railway, and over 2,000 miles of roads, which put English provincial roads to shame, without borrowing a penny, and are now engaged in extending their railway through Johore to Singapore. At the close of the year 1905, the capital account of the railway stood at 37½ million dollars.

There is still a wonderful deal of misconception of the nature of the Malay. I am frequently asked if treachery is not one of their characteristics, and I unhesitatingly answer, No. This particular misconception was probably initiated by the original merchant adventurers, and we can imagine what reception a body of strange, uninvited white infidels would receive at the hands of Mohammedan Malays whose system of warfare, taking its rise from the nature of the thickly jungle covered country they inhabit, which forms a natural series of fortifications, is adapted more for ambuscades than for fighting at close quarters. Add to this that, being Mohammedans, they were by their religion justified in indulging in piracy and murder where the victims were infidels. The Malay is possessed of at least as much passive courage as the average Englishman, and is probably less troubled by the fear of death and the hereafter than many Christians.

The East, as we know, was the cradle of good manners amongst other things, and the motto "manners maketh man" was, I am sure, in vogue there long before it spread to this country. The Malay, man, woman, and child, noble, peasant, and labourer, is a thorough "gentleman," and in facility of expressing himself, and in his knowledge of the very many things that can be acquired without board-school education, there is no comparison between him and the English son of the soil. I am a lover of the Malay, having known him intimately for over 30 years, and may be prejudiced, and as, furthermore, I cannot detain you much longer, I will refer those of you who want to improve their acquaintance with him to the fascinating description of the Peninsula Malay which will be found in Chapter VII. of Sir Frank Swettenham's "British Malaya."

As to the future of the Malay, I think much can be done if the sympathy which I have referred to as the keynote of our success hitherto is maintained, and on the subject of his education on modern lines would ask your attention to extracts from a letter I received at the end of last year from Mr. R. J. Wilkinson, the then head of the Educational Department. He is referring to a residential school for Malays in the establishment of which I took great interest before retiring from the service:—

"I have just concluded my examination of the Kuala Kangsar Residential School, and I feel sure that you will be interested in the result. The success of the school has exceeded my wildest hopes. I gave the boys the stiffest examination I have ever set in the Federated Malay States, yet 21 boys, including six Rajas, passed with flying colours. They all get 7th standard certificates, and are, of course, qualified for Government service, but most of them will remain on at the school for further instruction. As there are only 80 boys in all at the school, from the A B C class upwards, the proportionate success is quite unprecedented in the Straits and Federated Malay States records. . . . . The most interesting successes are those of Raja Kamaralzaman and of Raja Abdul Aziz, son of the late Perak Raja Muda; the other successful Rajas are more distant connections of the Sultan, but Raja Rashid, a son of the Sultan of Perak, very nearly passed, and is sticking to his work gamely, while the eldest son of the Raja di Hilir has joined the school and is doing most creditably.

The Yamtuan of Negri Sembilan is sending two young sons to join the school after holidays. His two brothers have improved immensely and are devoted to their work and to the school. I am the more pleased at the result because the boys sent to the school were by no means picked boys. The Governor has sanctioned the erection of the new building, and when it is up we shall be able to double our numbers. The Raja Muda of Kedah wishes to send his boys to the school. . . . But whatever happens the results now obtained will eventually dispose of the fiction that the Malays are not capable of being instructed. That 21 boys in a small school of 80, badly housed and ill-equipped should pass a very stiff seventh standard examination, shows that a few good schools could soon supply our Government offices with every clerk we need and make us independent of the Jafna Tamil."

On the other hand, I must admit that the Malay, owing to his environment—the balmy climate making no severe calls upon him in the matters either of food, artificial warmth or clothing—has not the bustling energy of the white man nor the greed for amassing wealth of the Chinaman, nor does he believe in putting forth unnecessary energy for a problematical gain—he is like the English tramp who was always willing—that is to look on at other people working, or like that one who complained that he was an unfortunate medium, too light for heavy work and too heavy for light work.

You will ask what has been the practical outcome of all the efforts I have endeavoured to outline for you, and I can give you, in a brief form, a suggestive idea which you can elaborate for yourselves from the following extract from Sir John Anderson's first report to the Colonial Office after his appointment as High Commissioner, in April, 1904, asking you to bear in mind that Sir John went out straight from the Colonial Office, where he had necessarily acquired the latest and fullest information as to other colonies and Protectorates. Sir John wrote :—

"Not only has law and order been firmly established throughout the whole area, but so far at any rate as the three western States are concerned, they are better provided with roads and railways, public buildings, and all the usual adjuncts of administration and comforts and amenities of civilisation than any of the Crown Colonies of the Empire."

I must not burden you with statistics, and in place thereof I will read for your information what was written in 1904-5, by Mr. Alleyne Ireland, Colonial Commissioner of the University of Chicago, for the purpose of visiting the Far East and preparing a comprehensive report on Colonial Administration in South-Eastern Asia. He says of the Federated Malay States :—

"Their present importance lies in the fact that they furnish the world with more than two-thirds of its total tin supply. As a general indication of the rank into which they fall as part of the British Empire it may be mentioned that their annual revenue is equal to that of Ceylon, exceeds that of Hong-kong and the Straits Settlements added together, and is nearly double that of the whole of our West African Colonies."

As regards tin the following figures of the world's output for the twelve months ended 30th September last should interest you :—

	Tons.
Straits (mainly from the F. M. S.) ..	56,767
Australia	5,065
Banca (Dutch, once a British possession)	9,418
Billiton (Dutch East Indies)	1,810
Bolivia	15,119
Cornwall	4,800
	92,979

The present price of tin is somewhere about £190 per ton. You will understand, therefore, that the main wealth of the Federated Malay States consists of their unrivalled deposits of tin ore, which in the shape of export duty contributed during the year 1905 over a £1,000,000 sterling towards the total revenue for that year. The labour force employed at the mines is chiefly Chinese, with comparatively few Indians, a class which is steadily increasing in number, and for the year to which the above figures relate was estimated at 230,000.

The Chinese miners are recruited from Southern China and do not bring their wives and children with them, nor do they become permanent settlers; they come and go, some under indentures, some as free labourers, and the general average of the labour strength is maintained. I hope to show you some photographs illustrating some of the methods of winning the tin ore, and for a further account must refer you to the appendix, conveying the latest impressions of an experienced mining engineer, Mr. Fordyce Balfour.

The total Chinese population of the States—miners, merchants, traders, shopkeepers, mechanics, coolies, &c.—number over 300,000, and they have hitherto been the main factor in the development of the country, and contribute the larger proportion of its revenues.

Whatever may be the case with South Africa, our Eastern tropical dependencies cannot be successfully opened up without the assistance of the Chinese in the first instance.

A second industry which is making enormous strides is that of rubber planting, but on this subject, as a special paper will shortly be read in this room by an expert, I will not enlarge beyond saying that the Superintendent of Agriculture in his report for 1905 estimated the area then alienated for the planting of Para rubber in the States, at 100,000 acres, of which about 38,000 had already been planted up, the number of trees of all ages, a number since largely increased, being put at 6,000,000 to 7,000,000. A recent return gives the number of rubber estates in the Federated Malay States alone as 143, of which 80 are the property of public companies, with a large amount of nominal and paid-up capital, the remainder being privately owned.

The revenue raised in the States during 1905 approached £2,500,000, and the expenditure over £2,000,000. The balance of assets was considerably in excess of £2,000,000. There is no public debt. The trade of the States in the same year—imports and exports—amounted to the value of over £13,000,000.

If you let these figures and those which I have given for the other countries mentioned in this paper, sink into your minds for a few minutes you will agree with me that these colonies and protectorates, which have not and do not cost the British taxpaper a farthing, and which are increasing in prosperity year by year, are worth cherishing, holding and defending.

In conclusion, allow me to quote a short passage from an article I recently saw in *The Times* newspaper:—

"There is perhaps no conviction more deeply rooted in the mind of the English people than that, of all the glorious features in their long history, the noblest is the rule which they have extended over alien races. They know that since the fall of the Roman Empire no State has had to bear a burden of this kind which can compare with that which they have borne and yet bear. They are proud of the virtues, the sagacity, the courage, and the tenacity by which generation after generation has built up the wonderful fabric. They are prouder still of the enlightenment, the humanity, the patience, and the self-denial with which it has been administered. They sincerely hold that no human institution has ever done so much to promote the welfare of mankind, and particularly of the weak and of the humble who have come beneath its laws."

APPENDIX I.

Features of the Peninsula.

In writing about the geological formation of the Federated Malay States it will be necessary to treat the Malay Peninsula as a whole. The Peninsula is, roughly, 800 miles long, extending from Lat. 14° North to Lat. 1° North. A range of mountains runs the whole length and extends far North through Siam, Burma, and the Shan States. Towards the South end the Peninsula widens out considerably, reaching a width of about 150 miles. Here the range loses its individuality, and is split up into many spurs and other smaller ranges. For the greater part of the 800 miles the range is nearer to the Western seaboard than to the Eastern. The whole of the country is, comparatively speaking, covered with thick impenetrable jungle which makes the study of its geological features extremely difficult and costly, so that even to the present day only a few facts regarding these features are known. There are one or two large rivers which form in certain parts the only means of inter-communication. The tin-bearing areas may be said to extend from the Northern boundary of the State of Johore, covering more or less the whole width of the Peninsula, right through the Federated Malay States, Siamese Malay States, Siam, and Burma. There is the possibility of the whole of the Peninsula being proved to contain tin in more or less quantities. There are large areas in the Peninsula at present lying undeveloped because of transport difficulties. These difficulties no doubt will be, to a great extent, overcome as the country is opened up.

Geology.

As mentioned above, our knowledge of the geological conditions and features does not amount to much, and any opinion that may be formed can only be based on the facts at our disposal. All evidences so far go to show that the main range of mountains with many of the spurs are composed of granites. These granites are usually grey in colour, and are found in all states of decomposition. They vary greatly in character, some are extremely fine-grained, in others large well-formed crystals of quartz, mica (biotite), and felspar (orthoclase) are found. Tourmaline is also found in the granites, in some cases in such quantities as to give the granite a black appearance. The intrusion of the granites has had a great influence upon the overlying rocks. The clays have been metamorphised, contorted and tilted to all sorts of angles. The limestones are highly crystalline, white or grey in colour, and are in some parts of such a character that they are mined and dressed for building and ornamental purposes. They, as well as the clays, have been crushed and contorted by the upheaval of the granites. Laterite in places has been found in large quantities.

Tin.

Tin occurs in three forms:—1. Native tin. 2. Stannite (tin pyrites, sulphuret of tin, tin sulphide).

3. Cassiterite (tin ore, black tin, tin oxide). The only form to be considered is cassiterite, which is usually associated with the granites, slates, and limestones of the Malay Peninsula. It is is also found in this form in the alluvial deposits. It varies in colour from black to yellow, and the crystals, which have a high adamantine lustre, occur in squares, prisms, and octahedrons. Hardness from 6 to 7. Specific gravity from 6·4 to 7·02.

Lode Mining.—Lode mining in the Federated Malay States has so far not played a very important part in adding to the monthly output of cassiterite. It is to be hoped, however, that honest efforts will be made to bring some of the known workable lodes into a well-developed condition. The best example of lode mining in the Federated Malay States is in Pahang. Here the lodes vary from 2 to 10 feet thick, and their value varies from 1 to 15 per cent. of cassiterite. The lodes are in the slates, and are said to penetrate the granites. The geological features here are the usual, viz., granites overlaid by varieties of Schists. Limestone is also found in the district. There are deposits of cassiterite found in the limestones, the best known example being at Lahat, where the tin is found in a matrix of hard crystalline limestone.

Impregnations: Contact Deposits and Stockworks have not, up to the present, been exploited to any great extent, but as the country is opened up, and when prospecting for tin along contacts between slates and granites takes place, there will probably be numerous discoveries of payable deposits. The best known example of a stockwork is at the Bruseh Mine, where the slates have been impregnated with cassiterite in small, thin, irregular deposits. The percentage of tin is low, but as the hills of slates lend themselves to working hydraulically, and as abundance of water with a good head is available, working costs are kept at a low figure. This mine is a good example of how experience and practical knowledge have brought what was anything but a paying concern to one that has a future.

Alluvial Deposits.—The past and present prosperity of the Federated Malay States is entirely owing to the ease with which the alluvial deposits carrying cassiterite have been discovered, their immense area, and their exceeding richness. That these known areas have yielded their best, and that their returns may now be said to be on the decline, goes without saying, and if other areas are not opened up the yield from alluvial sources will show a distinct fall. It does not enter into the scope of this sketch to discuss the origin of alluvial deposits in the Federated Malay States further than to say that all such deposits are the result of disintegration and denudation of pre-existing rocks. Large areas are being and have been worked for cassiterite, but the largest and richest deposit discovered so far was the one in the Kinta Valley. Deposits along sea beaches have been found, but nothing much in the way of proving their value and working them has been accomplished. Alluvial areas are necessarily formed in valleys and lowlands. The deposits are composed of what is called an overburden covering pay gravel. There are different kinds of deposits, and they may be classed as follows:—surface, shallow, and deep. The surface deposits may be of any thickness, from a thin layer to 20 feet and carry more or less tin ore from the surface to the bedrock. Shallow deposits are deposits covered by an overburden, varying in thickness from 1 to 30 feet, the "wash dirt" or gravel carrying the cassiterite may be of any thickness, but usually is not more than 20 feet. There are several instances of more than one layer of pay gravel being met with before bedrock had been reached. There is reason to suppose that in former days what was considered bedrock was not such but really an intervening layer of barren wash which may or may not have covered another bed of payable wash dirt. As these areas have been covered over by the tailings from the former mining operations nothing can prove this but drilling and prospecting the supposed worked out deposits. Several cases are known where the supposed "kong" or bedrock was pierced and another layer of payable "wash" found. Deep deposits may have anything above fifty feet of overburden and may require to be mined to show profits. This is certainly the best way, other conditions being favourable, to work such deposits. The Federated Malay States show several instances of this character, and it says much for the Chinese owners that they have faced their difficulties, and instead of removing great thicknesses of overburden have adopted a method of underground mining.

The overburden usually consists of the ordinary soil and other sedimentary deposits, and may be made up of one or more distinct beds or layers, showing different periods of deposition. The character of the "pay gravel" varies considerably. It may consist of fine sand, clay, clay mixed with pebbles, or free gravel (which has in some cases become cemented) composed of the pebbles and boulders of slates, schists, granite, pegmatite limestone, and gneiss. Other minerals are sometimes associated with the tin oxide such as tourmaline, wolframite, magnetite, cerussite, hornblende, ilmenite, iron and arsenical pyrites, none of these being of any great value. Small quantities of gold have been found in the alluvium. The bedrock is called "kong" by the Chinese miners. The bedrocks of the alluvium are usually china clay, the bleached surfaces of the schists, limestone and granite.

As chinese miners never make any estimate as to the value of their ground—simply stopping work on any area that does not return profits, although it is said that some mine owners have carried on their mining operations at a loss, depending upon the sale of opium, &c., to their workers to recoup themselves—no data are at hand to enable one to calculate the average value of the alluvium. Conditions and circumstances make certain values profitable or otherwise. In the Kinta Valley the average value is given at

about 1 per cent. of tin oxide, and the metallic contents of the ore would run from 60 to 72 per cent. In the Kinta Valley and in other parts very rich pockets of tin oxide have been struck; in some cases the "wash" has yielded 60 per cent. of oxide. Such "pockets" are not often met with.

The method of working the deposits is very simple. Coolies remove the overburden and when the "pay gravel" is reached it is carried up to a sluice where it is worked up with rakes, &c. The pebbles are thrown out to one side and the water running over what is left carries away the sand leaving the cassiterite behind, which is collected. Further cleaning with hand jigs takes place before it is smelted. Where the grains are of one size this simple treatment gives a fair recovery, but where there is fine tin oxide it is lost. This is easily proved by "panning the "tailings" coming from the sluices. Up to the present Chinese methods have prevailed so far, and many Chinese have made large fortunes, but the time is at hand when large areas containing low values will be handled by machinery. The resources of the Federated Malay States are anything but played out. The lode formations are practically unknown. Large returns may yet be got from impregnations and contact deposits which, to my mind, form the source of all the cassiterite in the alluvium. Other areas of alluvial deposits are only waiting the arrival of the intelligent prospector. A certain development has already taken place especially in the state of Perak where machinery is being used to some advantage, but to my mind greater developments will follow, and the main object will be the elimination of the coolie. That the cubic yard can be shifted by coolie labour at a very low figure is granted, but properly designed machinery with practical men in charge will be the means in the near future, and will treat the cubic yard at a very much lower figure than at present.

JOHN FORDYCE BALFOUR.

APPENDIX II.

RACES OF INDO-CHINA.

The term Indo-China is singularly happy, for the first point which has to be considered is the broad line of distinction between the aboriginal races of Indian origin and those of Mongolian descent, between the Malayan race for instance, and the Indonesians. Keane distinguishes the *Indonesians* as the pre-Malay "Caucasic" element in Oceania,* and *Malayan* or *Protomalayan* as the collective name of the "Oceanic Mongols," and *Malay*, as a particular and specialised branch of the Malayan (*i.e.*, Oceanic Mongol) family. Deniker says (without precisely defining the race alluded to) that "Indonesian" is the collective name given to the fairly pure inland races of the large islands (Java, Sumatra, Borneo, for instance) of the Archipelago, and perhaps if what he intends is that it should connote Keane's ("Caucasic") *pre-Malays*, this will be the best means of reconciling their views. The distribution here followed is mainly Deniker's. They are short (1·57 m.) ("mesaticephalic" to "dolichocephalic"), yellow-skinned with hair either straight or slightly waved, and differ widely in many ways not only from the Protomalays or Malayans, but from the Polynesians (somewhat awkwardly called by Keane "Caucasic" Indonesians), who are very tall and fleshy, usually described as short-headed (brachycephalic), with light brown or cinnamon-coloured skins, straight black or wavy black hair, and remarkably regular, sometimes quite European features, and who may be represented (as was pointed out in 1901 in the Report of the Cambridge Expedition to the Siamese-Malay States, read at the meeting of the British Association in that year) by the so-called "Malays" of Kelantan and Patani on the East Coast of the Peninsula. These "Malays" to some extent resemble the Maoris, though there are differences, and it is possible they may represent a less developed branch of the same race. The Indonesians are represented by the Battaks, Nias, and Kubus of Sumatra, the Tagals of the Philippines, the Dayaks of Borneo, Nicobarese and Nagas. According to some authorities the Indonesian type is also present modified by "Hindu" (*sic*) elements in the island of Java, and with Mongoloid elements among the Khamti and elsewhere.

In Indo-China there are both the probable aborigines and the mixed races produced by crossings between these aboriginal races and invaders from neighbouring countries. Of the former there are eleven chief groups, of the latter five.

A.—Of the aboriginal races, there are the following divisions:—

(1.) The Mois (Peunongs of Cambodia), Khas of Laos, uncivilised tribes scattered over the mountainous country between the Mekhong and the coast of Annam; as a rule short (1·57 m.), long-headed, more or less wavy-haired, straight-eyed. Differing greatly from Annamese and the Thại (who are both Mongoloid races) they are probably Indonesians. Hunters or husbandmen (of a very simple type), they go almost nude, and employ spears and poisoned arrows.

(2.) The Kuis, in south-east Siam and in north-west Cambodia, also in Keng-Tung (Shan States). They are short (1·63 m.), and the head is inclined to be short (brachycephalic); they speak Cambodian, and are good smiths.

(3.) The Mons or Talaing, remnants of a (according to Keane, old "Dravidian") race which once covered

* There are in reality two forms or types of what Keane calls the "Caucasic" element in the region here discussed (1), an undeveloped or aboriginal type represented by the Veddas [often called "Dravidians" the equivalent of Keane's Indonesians, though this is taken exception to as possessing a merely linguistic connotation] and (2) a more developed or specialised type, as represented by the tall brown-skinned Polynesians. If this fact is borne in mind it will clear up many apparent discrepancies. Frequent mention is made of "Malayo-polynesian" elements, but it must be remembered that this term is also properly confined to language.

the whole of Lower Burma, driven into the unhealthy deltas of the Irrawaddy, Salween, and Sittang. The Talaing language is the oldest literary vernacular of Indo-China, but is fast dying out, and is practically unknown outside a very limited range, though it is the original tongue from which as a model Burmese literature took its inspiration, and in which were composed the Peguan chronicles commencing in about the 6th century A.D., and recently edited by P. W. Schmidt.

(4.) The Cham (inhabitants of Champa) are closely allied (in language, though probably not in race) to the Malayan family; indeed, MM. Aymonier and Cabaton, in their admirable dictionary of the Cham language recently published, state that they regard the language as properly a Malayan dialect, and to anyone who has a good knowledge of Malay the correspondence is striking. Their alphabet is of Indian origin, and they inhabit parts of Southern Annam, Cochin China (Baria), and Cambodia. They are the existing representatives of a once powerful race, the founders of the empire of Champa, which included the whole of Annam and South Tongkin. A few are Mohammedan, but most are animist. They are handsome, with almost aquiline nose, eyes without the mongoloid fold, wavy or frizzy hair, and dark skin. It is the woman who asks the hand in marriage (contrary to the custom of other Indo-Chinese races).

(5.) The Karens are found in the less accessible parts of the Irrawaddy delta and the hill country to the east and south-east from which they spread into Siam. The ordinary Karen is distinguishable from the Burman chiefly by a difference of expression in the eyes. They are also found in the country between the Sittang and the Salween (Red Karens), and probably came into Burma* later than the Mons. They are short (1·64 m.), sturdy, with straight black and even brownish hair, light-brown skinned, and seem "half-way between Malays and the Thai." A less common type possesses the regular features, long oval face, pointed chin, and aquiline nose of the European.

(6.) The Chins inhabit the hills between the Irrawaddy and Bay of Bengal. They vary greatly in type, and are often of poor physique. Their dialects are classed with Burmese and Kachin.

(7.) The Kachins inhabit the extreme north of Burma, and were advancing southwards when their course was checked by the British annexation. They are believed to be a later uncivilised branch of the same stock as the Burmese, often have long straight noses, and are hardy and warlike.

(8.) The Nagas of Manipur and the northern ranges are fairly pure Indonesians. Various peculiarities, such as head-hunting, and many coloured hair or feather ornaments, long shields, breast-plates, methods of weaving, and communal houses connect them with the Dayaks and other Indonesians.

(9.) The Salons (or Selungs) are classed by some as Indonesians, by others with the Jakun, or aboriginal Malay races. They number only about 1,000. They are Orang Laut (Kipling's "Orange Lord," though this version hardly indicates the correct pronunciation) or Sea-gypsies, and live in the Mergui Archipelago wandering from one island to another. They pass their entire life in their boats, in what may appear somewhat confined and miserable quarters, but from which they seem to suffer no real inconvenience. They are wonderful divers, and collected pearls until the shallower waters were fished out. They still collect green snails, zostera (seaweed), *bêche de mer*, and other marine products, and employ the harpoon, which they follow up by diving into the sea after it.

(10.) We now come to the Pagan races of the Malay Peninsula, of which there are three well-defined groups, the most northerly being the Semang, roughly speaking opposite the island of Penang, the Sakai occupying the centre of the peninsula, more especially south-east Perak and north-west Pahang, and the Jakun, a composite race, with Malayan speech and culture, commencing in Selangor, and extending to Johore and the islands beyond, and including Singapore. The first of these races may be described in its purest type as consisting of woolly-haired tribes, the second (Sakai) as wavy-haired, and the third (Jakun and Orang Laut) as smooth or straight-haired tribes. The problem which here confronts us is how to trace the origin of these races There are no existing records to assist us, and all we have to go by are racial characters and language. As far as the evidence goes, the Khmer and Annamese tribes came from the southern boundaries of China, and spread out like the spokes of a fan towards the north of India, Burma, and Indo-China, the result being that it is possible to trace a connection both in language and race between the Malay Peninsula and the extreme west of the North-west provinces of India.* Before the Burmese and Siamese invasion the Mons lived in Pegu, the Khmer in Camboja, and the Annam in Tongkin, the latter gradually working down the eastern coast of Indo-China. The question is whether the Sakai belong to the so-called "Dravido-Australian" (*i.e.* "Indomesian") race, allied to the Vedda, Korumba, and Australian blacks, as suggested by Virchow, or whether they were of Mon-annam or Mon Khmer origin, as suggested by Schmidt. The argument of language is notoriously unsafe, and as the Mon-Annanese were a race partly at least of Mongolian origin, the writer finds it hard to accept this view as stated. Whatever linguistic group the Sakai belonged to, they unquestionably belonged racially to the Indian family, and not, even in part, to that of the Chinese. They may thus proprobably be best classed strictly with the Indonesians, as defined by Keane. It has been suggested that there were two waves of Mon-Khmer influence in the peninsula, one of which was due to the spread of a civilised Mon-Khmer empire, of which no distinct

* For a good coloured race-map of Burma, see Scott-O'Connor, "The Silken East." Hutchinson, 1904.

* See Blagden's race-map in "Pagan Races of the Malay Peninsula," Vol. II., pt. iv.

record survives in history, the other being an irruption of uncivilised members of the same races.

Taking the three aboriginal races of the peninsula in order, we get:—

(1.) The Negritos, belonging to a race which is short (1·49 m.) of stature, short-headed (brachycephalic), dark-skinned (glossy-black to chocolate brown), woolly-haired, round-eyed, and includes (*a*) the Aeta of the Philippines; (*b*) the Semang or Pangan of the Malay Peninsula; and (*c*) the Negritos of the Andaman Islands. The Semang (Negritos of the peninsula) or Pangan (short, round-headed, brachy to mesaticephalic, and woolly-haired, and with skin either chocolate or of a glossy black), live by hunting and by bartering jungle produce (honey, camphor, gutta, eaglewood, &c.), which they exchange with the Malays.

The Semang are in no way connected either with the Papuan or the African negro, both of which theories have been somewhat absurdly advanced. They wear fungus string girdles, dwell in temporary weather screens, round huts, or long communal shelters, which are furnished with bamboo sleeping platforms, and use the bow and arrow in place of the blow-pipe, except when in contact with Sakai. They eat practically "everything that is digestible" though there is no evidence that they ever were cannibals.

(2.) The Sakai of Perak, who are of medium height, light-skinned, long-headed, with wavy hair, and have much the best and most interesting features of all the Peninsula races. The Sakai wear porcupine quills through their noses, tattoo their faces, and use back combs with magical designs to ward off diseases. They employ the blow-pipe, in some instances a single length or internode (about 8 feet in length) of a particular kind of bamboo (*Bambusa wrayi* or *longinodis*), which is only known from one or two mountains in the Peninsula.

(3.) The Jakun, or "savage Malays" (*i.e.*, aboriginal Malayans), divided into land and sea tribes. Fairly pure Jakun occur on the Pahang Coast and Negri Sembilan, but elsewhere generally much modified by Negrito and Sakai elements. In fact, the Jakun taken as a whole are really a mixed group consisting of tribes partly aboriginal Malayan, partly Semang, and partly Sakai. The *pur-sang* Jakun, like the Malay, are of Mongolian origin. Their social organisation, which is of the Malayan type, is of a markedly higher order than that of either Negrito or Sakai. They perform mimetic dances accompanied by songs by way of representing birds, beasts, and other denizens of the forest, employ a peculiarly primitive kind of blow-pipe, have their marriages (of which the chasing of the bride by the bridegroom is an integral part) performed in presence of a peculiar artificial mound, and erect a diminutive soul-hut near the graves of their dead.

B.—The mixed races of Indo-China, a blend of the aborigines and the invaders, are as follows:—

(1.) The Cambodians or Khmers are taller than Annamese or Thai (1·65 m.), and are shorter-headed (brachycephalic) with (often) wavy hair, and eyes rarely oblique. Before the Annamese arrived, 200 years ago, they occupied the whole of Cochin-China. They have remained fairly savage, in spite of the beautiful monuments in their country.

(2.) The Annamese, who inhabit the Annamese coast, the delta in Tongkin, and most of Cochin China, with colonies in Cambodia, Laos, &c. They number from 15,000,000 to 17,000,000, and are in race akin especially to the Thai. They are short (1·58 m.), slender, short-headed, angular-faced with big cheek bones, and eyes slightly oblique. As a type they are very uniform. Their life is that of the Chinese. Socially, the village community, patriarchal family, and ancestor-worship form the foundation. Their Buddhism is superficial.

(3.) The Burmese (Mranma or Mramma), supposed to have come from south-east Tibet, and often referred to as a race of the Tibeto-Burman stock. They are a race of generally Mongolian character, but have straight eyes, and a warmer tint than the races to the east of them, and are more mercurial and artistic in temperament. They follow Buddhism in its purist form, and have long had elementary education. Arakanese is the most archaic dialect. They live in Upper Burma, Pegu, and Arakan, in a country part of which was occupied by the Mon (Talaings); the Arakanese differ slightly from true Burmese. They are short of stature and comparatively short-headed (mesaticephals).* Their language is toned.

(4.) The Thai were the latest to arrive. Their country is from the frontier of Burma Proper to Cambodia. In the north they are represented by races said to be allied to the races of Tongkin and China, and include certain tribes (of Tongkin and Southern China), the Shans (Upper Burma), the Laos, and Siamese. The Siamese are of medium height (1·61 m.), olive. One type has big cheek-bones, short flat nose, lozenge-shaped face. They speak a toned language, and are devoted Buddhists, and the most civilised of all the branches of their stock, having retained their independence in spite of severe pressure from neighbouring nations. In the Malay Peninsula they mix with the Malays; the mixed race resulting is called "Samsam," and represents some curious problems in race-fusion.

(5.) The Malays of the Peninsula (a specialised branch of Keane's "Oceanic Mongols") are an off-shoot of the South Mongolian stock; straight-haired (bluish-black coloured), almost beardless, with skin of a dark yellow brown or olive (or the colour of "newly-fallen leaves"); round-headed (brachycephalic), often with more or less flattened noses, somewhat thick ears, 1·61 m. in height. They are closely allied to the aboriginal Malay or Jakun race of the Peninsula (only, of course, where the latter approaches the pure type). They arrived in the Peninsula from Central Sumatra, where they were moulded by Indian influences into a more or less

* Mr. R. Grant Brown has kindly read the notes relating to the races of Burma.

civilised condition before they came over. When they arrived they found the country already occupied by the three pagan races (Negrito, Sakai, and Jakun), whom they drove before them into the jungle. It is thought besides, that at the time of their arrival they found the Mon-Khmer races occupying the same relation towards the pagan races (*i.e.* in possession of the coast line and points of vantage) as they (Malays themselves) do to-day, and that they partly absorbed the Mon-Khmer and partly drove them too into the jungle. This question, however, of the Mon-Khmer element in the Peninsula is still essentially an open one.

The Malays proper are but superficially civilised—a graft upon a savage stock. The natural savagery of their disposition continually threatens to break out, and not infrequently actually does so in the form of the *amok*, for instance, which was till the strong arm of British law made it too risky to indulge in and therefore unfashionable, the national Malay method of committing suicide. Another striking proof of the nervous excitability of their temperament is the strange disease called "latah." Apart from this tendency the Malay character has much in common with the Mongol, being under ordinary circumstances gentle, peaceable, quiet, civil, obedient, and loyal, but at the same time proud and sensitive to the point of honour, and with strangers especially suspicious and reserved. When free from the trammels of civilisation, the Malay is of a frankly bold and savage stamp, and makes an excellent soldier. He has been frequently charged with the sin of laziness. But although it is only natural that he should take life easily in a climate where the fruitful soil supplies with a minimum of exertion his simple wants, it is yet an open question whether this laziness is not largely due to the recent employment by his rulers of the "Krah," or system of forced labour, and also of slavery, which until quite late years rendered it impossible for the Malay labourer to reap the natural reward of his toil. Among the national institutions of the Malay race may be mentioned pile-dwellings, the blow-pipe and the Kris, the sarong, the filing and blackening of the teeth, the Balei, or council-house, and a strong belief in animism. Their traditions and romances contain references to human sacrifices, which appear to have been not long discontinued. They have mechanical skill of a high order, and are adepts in all crafts belonging to the jungle and the sea.

In spite of their being animists at heart the true Malays are frequently most fanatical Mohammedans, in contradistinction to the Battaks who are the hardest to convert. Their language is agglutinative, the roots as a rule being unchanged, and new words formed by means of affixes, infixes and reduplication. The roots are mostly dissyllabic, the derivations frequently very numerous, and the juxtaposition of consonants avoided, the most vocalic of all the dialects of the Peninsula being that of the Kelantan and Patani "Malays," which approaches in this respect the vocalic character of the dialects of the Pacific Islands.

Other Races Mentioned.

C.—(1). Java:—The Javanese are not of one uniform race, and may be divided into the Sundanese on the west, the Javanese in the east, the latter being mixed with "Hindu" (*sic*) elements. In the west of the island are the Baduj, and in the east part (Pasuruan) the Tenggerese, both heathen Indonesians of the savage type. The Madurese, Boyanese, and the Balinese resemble the Javanese. Java is of especial interest as the home of the Trinil, *Pithecanthropus erectus*, the upright ape-man, whose cranium is intermediate between the Neanderthal and Spy crania and that of the chimpanzee and hence the nearest link hitherto found between "ape-like men and men-like apes." It is significant that traditions of a strange man-like ape are widely current also in the Malay Peninsula.

It should be added that the magnificent sacred buildings of Java (*e.g.*, Brambanan and Borobudor) and Sumatra are of Indian type, and so with most of their culture. In Java especially the apostles of Indian culture had such success that their Javanese pupils became famous as musicians and as artificers in precious metals, even though these latter were not found in Java, and their ancient religion as well as that of the Malay Peninsula, is, although superficially Mohammedan (except in the Tengger and Padig districts) in point of fact, founded upon a Brahmanic or Hindu type overlying pure Shamanism. In Java the Hindu power was overthrown in 1478, after which Mohammedanism spread throughout the island.

In Java, inscriptions written in Kawi (the ancient Javanese language) survive from the eleventh or twelfth century, and it is evident from numerous archæological remains that Hinduism was introduced early, both in its Buddhistic and Brahmanical forms.

(2). Sumatra:—The northern extremity is peopled by the Achinese, Indonesians with Arabic admixture. In the south are the Palembangs (of Javanese origin), the Rejangs, described as Malayo-Javanese, the Passumahs, Indonesians with Javanese admixture, the Lampongs (or Passumahs crossed with Sundanese). On the west coast and its adjacent islands are races resembling the Battaks (*cf.* the Nias-Engano group), and off the eastern coast are mostly Malays. The cannibal Battaks are also Indonesians, good craftsmen, inventors of an alphabet and possessors of a literature.

(3). Borneo:—Malays on the coast, except the north-east, where are Sulus (Indonesians with Arabic admixture from the Sulu Islands), Bugis, Bajaus. In the central highlands, are tribes of Indonesian origin (Kalabits, Kahayans, Trina, &c.), that are in danger of being swamped by the tribes of the Kenyah-Kayan complex; in the north-eastern and north-western corners of Borneo, these Indonesian tribes (Dusuns, Muruts, Land-Dayaks) are in a more or less flourishing condition, as they have not been brought

into contact with more powerful immigrating tribes. The dominant Brachycephalic Sea-Dayaks may be regarded as Proto-Malays; their headquarters are the Batang Lupar and Saribas rivers of Sarawak, but their area of distribution is rapidly extending.*

(4). The Philippines are inhabited by the Negritos or Aetas ("Blacks") of the Interior, and a number of tribes of Indonesian origin, on the north-east Cagayane or Ibangs, the vicinity of Lake Cagayan in Luzon, and the Ifugaos (head-hunters): next the Igorrotes: next the Tagals; then the Mangianes (coast of Mindoro, east coast of Luzon, in the interior of the south, &c.). Then come the Ilocanos (west coast of Luzon), and also the Zambales and Pangasinanes of the south. The southern extremity of Luzon is inhabited by the Bicols (allied to the Tagals): West Mindanao is inhabited by Moros (fanatical Mohammedans, and pirates of mixed origin). East Mindanao is taken up by the Mandajas in the south, Bogobos in the north, and the Caragas tribe of Bisaya or Vissaya. Most of these last tribes are found in the rest of the Philippine Archipelago, north of Mindanao, and occur with Moros in Palawan. The Tagaloc dialect is spreading and superseding other dialects in the Archipelago.

WALTER W. SKEAT.

DISCUSSION.

The CHAIRMAN said that so many subjects had been touched upon by the author that he feared it was quite impossible for him to deal with more than a very few of them. It was difficult to pick out the points for discussion, because having been a Government official all his life he had been taught that he ought not to speak in public with reference to official matters, and nearly all the subjects of the paper had to do with politics of a sort. He also had in mind the unfortunate experience of another official, the Governor of Jamaica, who probably realised that it was a mistake to write; and though he (Sir Frank) was no longer a Government official and did not need to stand in great awe of the authorities, he could not even mention facts which were known to him, and it was very difficult to express an opinion upon them without giving some cause of offence. The paper dealt with a number of subjects which might be divided and classified into what this country had and what it had given away. The catalogue of our magnificent losses in the neighbourhood of the Malay Peninsula was something that he thought all present would take away and think about. At different times, Britishers had acquired for the country the practical control of Java, the North of Sumatra, the East Coast of Borneo, and Manila, which had been subsequently given up, not by the people who acquired them, who knew what they were worth, but by statesmen in this country, no doubt for excellent reasons if we only knew them. In exchange for islands which contained many millions of people and enormous undreamt of wealth, the Governor of Singapore, as Sir William had said, had now acquired a large number of high-sounding titles. For instance, he was the Governor of Cocos Island; he was the Consul-General of all that remained of Brunei, and also responsible for the Island of Labuan; but it was to be hoped that what had happened in the past would not occur again. This country had acquired a position in the Malay Peninsula, and it would be a great catastrophe if we were to lose it. The author had indicated what that position meant. Shortly stated it was that, by the foresight of one of the greatest English administrators, Sir Stamford Raffles, the British position was obtained at Singapore, and British influence and authority had gradually been extended up the Malay Peninsula. There was much yet that remained to be done. For instance, in his opinion the prosperity of Singapore was only just beginning, and it would be an appalling circumstance if anything were to happen which interfered with the proper interests of that place. It should be the aim of the authorities in the future to encourage every legitimate effort to continue the present successful policy. With regard to the work that had been accomplished in the Malay States, he desired to contrast that with the work done in other places. He had read in the newspapers that a certain amount of feeling had been developed in both India and Egypt against the authorities. He could say with the greatest confidence that that was not the case in the Malay States. If any agitator or foreigner were to go to the Malay States and endeavour to get the people to rise against the Government, he would find he had no listeners; in fact he had never in his life heard of either a foreign or native agitator in the Malay States. The people were entirely content and satisfied, and that he thought showed that something different had been done in regard to the administration of that tract of country from what had been done in other places. The actual rulers had been white men, who had endeavoured to better the condition of the natives of the place, and the best thing that could be said of the result was that the people were satisfied and did not feel that the white people were shutting them out; they did not feel that they were having taken from them something which was their birthright. The Government had given them more than they ever had before, and there was no feeling against the Government in any sense whatever. With regard to the social conditions of the States, he might speak on that extraordinarily interesting question, the Chinese, a question which, in this country, had had perhaps more than its real value attached to it; it had been used for purposes which he could not mention. But he understood that the subject of the Chinese in the Malay States was likely to attract the attention of the Imperial Government. There were

* I have to thank Mr. R. Shelford for these notes on the races of Borneo.—W.W.S.

people in this country who were so interested in the Chinese that they wanted them to give up what were called Chinese vices, such as indulgence in the eating and smoking of opium and the habit of gambling. Everything was a vice if indulged to in excess. Gambling existed everywhere. In that connection it must be remembered that the Chinese, who worked all day long, had no means of recreation whatever. The Chinese gambling haunt was not made particularly attractive, and there was nothing about it that would induce the natives to go there. In Europe, on the contrary, the gambling places were made extraordinarily attractive, and the most beautiful places in Europe were those where gambling was carried on to a degree of which a Chinaman never dreamed. Yet no one seemed to think that that was particularly offensive. He thought it was needless for people in this country to concern themselves about the Chinese miner, whose only form of amusement was to risk the money he had earned during the day in a gambling place, and probably lose it. With regard to the practice of opium eating and smoking, a Commission was appointed on that subject some years ago, and he thought the question was settled by the Commission. Nobody would dream of saying that to indulge to excess in the smoking or eating of opium was a good thing. There were many Chinese who did not smoke or eat opium to excess, and he had personally found they were quite as good members of society as people who drank, but did not drink to excess. He was sure all present had listened with the greatest possible interest to the excellent paper which had been read, and as it had been somewhat curtailed in delivery, he hoped they would take the opportunity of reading it *in extenso* when it appeared in the *Journal*.

Admiral the Hon. Sir EDMUND FREMANTLE, G.C.B., said that having had the pleasure of visiting the Malay States some years ago, when he was Commander-in-Chief in China, he felt bound to endorse all that the Chairman and the author had said as to the interesting States which were the subject of the paper. He remembered the Chairman kindly taking him over the gaol and various other public buildings at Perak, and he was very much struck with the fact that they were entirely up-to-date. When he compared them with the facilities which existed in Hong-kong at that time, the conclusion at which he arrived was that those in the State were at the top of the tree and the others near the bottom. The system of government was exceedingly well carried out, both in regard to the upkeep of the sanitary conditions and the supervision of the gambling. He believed he was correct in saying that everything possible was done in British colonies to stop gambling, but he was afraid the attempts were often unsuccessful. He remembered at one time, when some friends from England visited him, taking them round Hong-kong and showing them the Chinese gambling houses; and he was struck with the fact that, whether the Chinamen won or lost, they always paid up with a good spirit; they were extremely honest gamblers. With regard to the question of opium eating, he was assured by officers who commanded Sikh regiments that, almost to a man, they ate opium but in very small quantities; and that it would be as great, if not greater, punishment to stop their opium as it would be to stop an Englishman his beer. Nevertheless, the opium dens which he had seen in Hong-kong, Calcutta, and other places, were the most debasing spectacles imaginable; and in his opinion the effects of a drug like opium when used to excess were worse than the drinking of alcohol to excess. In many parts of the world he had seen British ideas carried out by British officers, not entirely in accordance with the strict regulations of the Colonial Office, but with marked success. The British public, as a general rule, were not aware of the state of things existing in the distant parts of the Empire; and it was useless for them to call a thing slavery or a brutality about which they had no idea, and to attempt to interfere in every detail of government. He hoped the people in this country would trust to the officials on the spot, and, bearing in mind that they were acquainted with the local conditions, believe that Englishmen, whether in distant parts of the world or at home, were full of those sentiments of humanity and justice which those present believed belonged to a great extent to the British race.

On the motion of the CHAIRMAN, a hearty vote of thanks was accorded to Sir William Treacher for his able and interesting paper.

Sir WILLIAM TREACHER, in acknowledging the vote of thanks, said he desired on behalf of the Council of the Society, and also on his own behalf, to express their deep thanks to Sir Frank Swettenham for so kindly presiding over the meeting at considerable personal inconvenience.

FIFTEENTH ORDINARY MEETING.

Wednesday, MARCH 20th, 1907; SIR JOSEPH WILSON SWAN, M.A., D.Sc., F.R.S., in the chair.

The following candidates were proposed for election as members of the Society:—

Aird, Mrs., 22, Eaton-square, S.W.
Charlier, Edgard, 19, Lerchenfeldstrasse, Munich, Bavaria, Germany.
Ghosh, Henry A., 9, Middle-road, Entally, Calcutta, India.
Griffin, John R., Kemble-street, Kingsway, W.C.
Khan, M. Habib ur Rahman, Habibganj, District Aligarh, India.

Mukharji, Sivnarayan, Uttarpara, near Calcutta, India.
Percival, Professor Hugh Melville, M.A., 14, Park-street, Calcutta, India.
Ransome, Ernest L., Westervelt-avenue, Tompkinsville, Staten Island, and 11, Broadway, New York City, U.S.A.
Reid, Hugh, D.L., J.P., M.Inst.C.E., Belmont, Springburn, Glasgow.
Reitlinger, Albert, 33, Fitzjohn's-avenue, N.W.
Wood, E. Escott, Hurricane-house, Brymbo, North Wales.
Woolner, A. C., M.A., Punjab University, Lahore, India.

The following candidates were balloted for and duly elected members of the Society:—

Cadell, Alan, C.S.I., Glenmara, Arthur-road, Wimbledon-park, S.W.
Conradi, Henry, 19, Ebbsfleet-road, Cricklewood, N.W.
Davies, Charles J., Milford Haven.
Fuller, George W., 170, Broadway, New York City, U.S.A.
Hayward, William Wyatt, 257 España, Lomas de Zamora, Buenos Ayres, Argentine Republic.
Midhut, Mohamed Hossain Khan, Office of Railway Board, Simla, and Zamania, Ghazipur District, U.P., India.
Myer, Reginald, 8, Ladbroke-square, W.
O'Brien, Hon. W. Turlough, 13, Egerton-place, S.W.
Ogilvie, Alec., 13, Holland-villas-road, Kensington, W.
Silberrad, Ch. A., B.A., B.Sc., care of Messrs. R. Silberrad and Son, 25, Savage-gardens, Crutched-friars, E.C., and Banda, U.P., India.
Testa, F. J., Honolulu, Hawaiian Islands.

The paper read was—

SMOKE PREVENTION IN FACTORIES AND ELECTRIC SUPPLY STATIONS.

By John B. C. Kershaw, F.I.C.

"Smoke prevention" is such a well-worn subject for papers and addresses, and has been so repeatedly discussed with, I regret to say, so little practical result, that I am well aware I am courting failure by adopting it as my subject to-night.

But the damage to health and property caused by smoke in the manufacturing and densely-populated centres of industry in this country is so enormous, and the gain to the community at large would be so great, if "smoke" could be banished from our towns and cities, that I feel justified in bringing the subject once again before the members of your Society, and through the medium of your *Journal*, before the larger public outside.

You will notice that my subject is, "Smoke Prevention in Factories and Electric Supply Stations."

I have purposely excluded the problem offered by *domestic smoke*, because this is entirely distinct in its character and method of solution from that of *factory smoke*, and in my opinion it will be most conducive to practical results to-night if we confine our attention to the one question: Is the smoke from factories and electric supply stations preventable?

While thus excluding domestic smoke from our consideration, I admit that in large towns and cities, and in the metropolis especially, the improvement of the atmosphere by the banishment of smoke is largely a question of the installation of gas-stoves and of other improved methods of heating for domestic purposes, and that this reform will have greater effect in clearing the skies than the smokeless combustion of fuel in factories. The aggregate amount of coal burned annually in London and in other cities of this country for purely domestic purposes is enormously greater than the amount burned in the same cities for manufacturing and similar operations, and the ordinary householder is a much larger contributor to the pall of smoke which covers him than he is aware. Like many another reformer, he is painfully awake to the shortcomings and defects of his neighbour's chimneys, while blissfully unconscious of the smuts produced by his own. But, while recognising that the smoke produced from factories and electric supply stations in London and in other cities of this country is only one-third or one-fourth of that produced by the ordinary householder, I do not agree with those who assert that on this account the prevention of factory smoke is entirely a secondary and unimportant matter. The evils produced by smoke are so great, and the pecuniary losses that arise from its emission are so large, that no factory owner or power station engineer ought to rest satisfied until he has done all that is possible to attain smokeless combustion of the fuel used for heating purposes in his own works. For the problem is not an insoluble one. I assert unhesitatingly, and not without knowledge of the difficulties of the situation, that the majority of factories and the majority of electrical supply stations located within the metropolitan area could even now carry on their operations without the emission of black smoke, if the heating and steam-

raising apparatus were properly designed and if the plant were placed under scientific control.

Why then has so little progress been made in this direction, and why is it the exception rather than the rule to find a factory or electric supply station in London with a clean record as regards smoke production? I answer because in the first place the plant has been badly designed, and because in the second place the owners and users are not sufficiently impressed with the necessity or advantages of altering it. Smoke prevention in the majority of factories and electric supply stations is, I again assert, at the present moment entirely possible and within the range of practical politics. I am therefore hopeful that as the information upon this subject increases, and fuel users are made to understand the practical advantages which result from the more scientific management of their heating or steam-raising plant, that chimneys belching forth clouds of evil-coloured vapour and black smoke will become a feature of the past. May we not also hope that as the knowledge of what can be and is being actually achieved in this matter spreads, we shall enter upon a new and cleaner epoch of industrial progress, in which manufacturers and station engineers will look upon a smokeless chimney as a *sine quâ non* of good management, and will feel it a personal insult when told that the chimneys of the works under their charge have been producing black smoke.

In this paper, then, I propose to describe briefly the principles underlying the methods by which fuel may be burned for heating and steam-raising purposes on a large scale without smoke-production, and to follow this with a short account of the organisation and work of a Smoke Abatement Society which is helping to spread this knowledge among fuel-users, and is assisting them in a most practical manner to attain the highest possible efficiency from their heating and steam-raising plant.

I.—The Principles of Smokeless Combustion.

Coal is a natural product which contains carbon, hydrogen, oxygen and nitrogen, in some form of physical state and chemical combination, which is not yet solved. For practical purposes, coal may be regarded, however, as a mixture of solid carbon and gaseous hydrocarbons, and it is the latter—namely, the hydrocarbon gases—methane, ethylene, acetylene and others of the same series, which cause the difficulty in burning coal without smoke.

The solid or fixed carbon unites with oxygen before it rises from the bars of the grate as carbon dioxide or carbon monoxide gas, and once in this form, it is never reduced within the furnace or flues to the solid state. The heat required to convert the molecule of fixed carbon into gaseous carbon, is also supplied by the combustion of the next lying molecule of fuel, and the combustion of the whole mass of fixed carbon is therefore progressive, and demands only two conditions—namely, an initial temperature of 700° C., and an adequate supply of air above and through the mass of glowing fuel.

The hydrocarbon gases given off by all fuels on heating, are much more troublesome to burn completely to carbon dioxide gas and aqueous vapour. These hydrocarbon gases vary from 6 per cent. in South Wales steam coal, to 35 per cent. in the bituminous coal from the northern coalfields, and the difficulty of obtaining smokeless combustion is therefore greatest with the cheaper and more generally used bituminous fuels. In the first place, the conversion of the solid carbon and hydrogen of the fuel into the gaseous state, demands a large amount of heat, and this heat is necessarily drawn from the solid fuel lying on the bars of the grate, and not from the burning gases.

A great reduction of temperature occurs therefore during the gasifying process, and unless the addition of fuel be wisely controlled, the temperature of the furnace may be brought so low that ignition of these gases fails to occur, and the gases are then simply distilled from the coal, and pass up the chimney unconsumed, as a brown and choking vapour.

These hydrocarbon gases, when escaping unconsumed at a low temperature, do not liberate soot, but they are deleterious to health, and their suppression on that account is certainly called for. Moreover, they represent a large proportion of the total heat value of the fuel, and their escape unburned is not conducive to the economical working of the plant.

Taking an ordinary bituminous fuel of the following composition: 70 per cent. coke, containing 10 per cent. ash and 60 per cent. fixed carbon, and 30 per cent. volatile matter; we find that the fixed carbon in each lb. of fuel burnt will produce 4,920 calories, while the volatile hydrocarbons will produce 2,859 calories, or 36 per cent. of the whole. To allow any portion of these gases to escape unburned is therefore a foolish waste of heat energy, and

yet it is one which occurs regularly at the moment of firing in badly-managed boiler plants, especially when an unskilled man is in charge of the boilers. For the complete and yet economical combustion of these hydrocarbon gases as they rise from the mass of fuel upon the bars of the grate, three conditions are essential, namely :

1. A temperature sufficiently high to cause the instant ignition of the gases. This is found by experiment to be about 670° C.

2. A sufficiency of air, preferably heated, to combine with the carbon and hydrogen of these gases, but not a large excess of the same.

3. A good admixture of the air and the hydrocarbons.

It is necessary not only that these conditions should be present initially, but that they should be maintained during the liberation of the hydrocarbon gases.

If the temperature be allowed to fall below 670° C., the gases will not ignite, while if the air supply be deficient, or if the admixture be bad, only partial combustion will occur, and solid particles of carbon will separate, which will later coalesce to form smuts and soot. The chemical changes which lead to smoke formation may be represented for practical purposes by the following equations, although Bone and Drugman have shown by recent researches that the changes are much more complex than was formerly supposed :—

$$2CH_4 + O_2 = C_2 + 2H_2 + 2H_2O.$$
Methane.

$$2C_2H_4 + O_2 = 2C_2 + 2H_2 + 2H_2O.$$
Ethylene.

$$2C_2H_2 + O_2 = 2C_2 + 2H_2O.$$
Acetylene.

Smoke is then caused, as a general rule, by failure to maintain conditions 2 and 3 of perfect combustion. When smoke is once formed, it is not possible on a large scale to secure its combustion, and only some form of smoke-washing apparatus will remove it from the chimney gases.

All the so-called "smoke-consuming" appliances are, therefore, mere devices to secure more perfect combustion of the hydrocarbon gases at the moment of their liberation, and in nine cases out of ten, they do not involve any novelty of principle or of construction.

II.—Practical Methods for Smoke Prevention.

The facts given in the preceding section of this paper show that the smoke problem is one which chiefly relates to the use of bituminous fuel, and that the perfect combustion of the other classes of fuels, liberating less than 15 per cent. of volatile hydrocarbon gases on heating, is not a difficult matter.

The furnaces originally designed and installed for boilers will, as a general rule, maintain the three conditions essential for perfect combustion with such fuels, and it is for this reason that in many of the London generating stations the high-priced South Wales steam coal is being used for steam-raising purposes, with notable effect upon the costs of supply.

The considerations advanced in Section I. however show, that bituminous fuel requires, for its perfect combustion, a large brick-lined chamber maintained at a temperature of from 700° to 1,000° C., in which the hydrocarbon gases and the heated air can mix thoroughly, and burn to CO_2 and H_2O, before they are allowed to come into contact with the water-cooled plates or tubes of the boiler. The size of this chamber must be proportioned to the volume of hydrocarbon gases liberated by the fuel, and therefore the character of the fuel supply ought to be taken into consideration when designing and erecting the boiler plant. If the furnace is to be hand-fired, some automatic device is also necessary whereby the draft is almost entirely cut off while the furnace door is opened for clinkering and firing purposes. When the firing is finished and the furnace door is closed, some mechanical device is again required for regulating the volume of air admission above the fire, and the period for which this secondary air admission occurs. Mechanical stokers with automatic and regular or continuous feed, obviate this difficulty of an intermittent secondary air supply, and it is for this reason that they have become so popular in large steam-generating plants. Finally, with all systems of firing, the complete combustion of bituminous fuel demands some device, for thoroughly mixing the heated air and hydrocarbon gases in the combustion chamber.

It is not my intention in this paper to give further descriptions of the methods by which bituminous fuels may be burned without smoke emission, and with high efficiency, in the furnaces of steam boilers and of heating apparatus generally. There are a large number of patented appliances and devices for attaining smokeless combustion now on the market. In so far as these embrace the features that have just been described, they may be held to be useful, though the validity

of the patents may in many cases be doubted. I have no hesitation in stating, however, that where these appliances are in use, though only relating to the maintenance of one of the three essential conditions, the emission of black smoke has been greatly curtailed if not altogether stopped.

A plant designed and erected in accordance with the whole of the practical recommendations given above, would be capable of burning the cheapest types of bituminous fuel with high efficiency, and with absolute smokelessness. I am hopeful that at a not very distant date I may be able to point to many such steam-generating plants in this country.

III.—The Organisation, Aims and Work of the Hamburg Smoke Abatement Society.

Two of the chief difficulties confronting the factory owner or station superintendent, desirous of improving the work of his heating or steam-raising plant, are those arising from lack of expert aid in its control and the scarcity of competent firemen. In large works, a specially trained chemist or engineer is sometimes given the sole charge of the boiler-plant with notable results as regards smoke abatement and economy, but in small works this plan is of course impracticable.

As regards the supply of competent firemen, this has always been deficient, and I have no hesitation in stating that a very large proportion of the smoke produced in this country is due to the low class of unskilled and untrained labour employed for firing the heating and boiler installations.

The Hamburg Smoke Abatement Society is a voluntary association of steam-users with works in or near to the city of Hamburg, which was formed in October, 1902, for the purpose of assisting its members in the better management of their steam-raising plant. The work of this society lies chiefly in the two directions indicated above. In the first place, a staff of engineers with special experience in boiler management is retained by the society, and these advise and report upon the boiler installations of its members. Special steam-raising tests are carried out at regular intervals of time, and every effort is made to bring each boiler installation up to a high level as regards smokelessness and efficiency. This solves the difficulty of "expert aid" for the small steam user.

In the second place, the society retains the services of two or more firemen instructors—these visit the different works of the members of the society, as desired, and carry out a course of instruction for the firemen employed. In this way a body of competent firemen has been created in the city of Hamburg, upon which the members of the Smoke Abatement Society can depend for efficient stoking of their boiler plants.*

A third direction, in which the Hamburg Society carries out most useful work, is in testing and reporting upon the value of new smoke abatement appliances or systems of firing. The society possesses a small model steam-raising installation where these trials can be carried out under the supervision of its own staff of firemen and engineers, and the reports upon these trials, issued to its members, form another valuable feature of its activities. Further information about the work of this society will be found in a paper contributed to the Conference on Smoke Abatement, held in London in 1905, and I may perhaps be allowed to quote here the concluding paragraph of that paper.—

"The practical lesson which we in this country may learn from the above account of the work of the Hamburg Society is, I think, that the smoke problem is to be solved, like many another problem, by application of that old English method of self-help, which is now sadly out of fashion. Manufacturers, and fuel-raisers generally, in this country, must be taught that the emission of black smoke is largely preventable, and that the smokeless combustion of fuel promotes economy, when carried out under proper supervision. It is for this reason that I have given instances from the annual reports of the Hamburg Society to prove the saving in fuel-consumption, which results from the working of steam-boiler plants on scientific lines, with properly trained stokers.

"What is wanted in this country, is some society or organisation which will provide fuel-users with the technical advice and oversight required for obtaining the smokeless combustion of fuel in their own works. The Hamburg Society, in my opinion, is such an organisation, since it is showing manufacturers how to combine together to attack the evil at its source—namely, the boiler and heating installations in their own works. It would be well if similar societies were started in every large centre of manufacturing industry in this country."

IV.—Conclusions.

I shall not be surprised if I am told in the course of the discussion which is to

* The London Smoke Abatement Society has recently commenced a similar work, and has appointed Mr. William H. Booth its official Lecturer. A course of lectures to Stokers is now being given by this gentleman at the Borough Polytechnic.

follow the reading of this paper, that I have advanced no new theory to account for factory smoke, and have proposed no new plan or remedies for securing its abatement. This is perfectly true, more true perhaps than some of my critics themselves realise. The principles of smokeless combustion enunciated in this paper were first put forward by C. Wye Williams, a Liverpool engineer, in the year 1839, and the following extracts from Williams's book entitled "The Combustion of Coal," will prove to you that he had a fairly correct knowledge of what was required to secure smoke abatement:—

"It may be asked how it has happened that hitherto this (the smokeless combustion of fuel) has not been effected? I answer because the chemistry of combustion has been neglected, not in the laboratory, but in practice; and because the construction of our furnaces has been too much left to those who know little of the chemical properties of the materials which are consumed in them. . . . . ."

"A charge of fresh coal thrown on a furnace already in an active state, so far from augmenting the general temperature, or giving out heat, becomes at once an absorbent of it. . . . . ."

"I have proved during the last fifteen years, that even in the largest establishments, and in the furnaces of steam boilers, the great nuisance of smoke may be avoided, and even with the accompaniment of considerable economy. . . . . ."

"In marine and cylindrical land boilers the combustion chamber is invariably made too shallow and too restricted."

Williams clearly pointed out that the combustion of bituminous fuel involved two distinct things, namely, the liberation and combustion of the volatile gases in a suitable chamber, and the combustion of the solid coke on the bars of the grate. In one place he described how he proposed to put into practice these principles of fuel combustion, and showed drawings of boiler furnaces with properly designed and scientific arrangements for providing a secondary and heated air-supply behind the bridge. He was very sarcastic at the expense of inventors, who, even in his day, were patenting devices for "consuming smoke," instead of attempting to show how to prevent its original formation.

The above extracts prove that this was altogether a remarkable book to have been written and published nearly sixty-eight years ago.

Williams's book was re-printed in 1854 and 1886, but its teaching appears to have had little effect upon the practice of boiler engineers, who still persisted in designing and erecting boilers with wholly inadequate combustion space for the class of coal that was burned.

The results of trials carried out by the Manchester Association for the Prevention of Steam-Boiler Explosions in 1867-68, were similarly ignored by boiler-makers and their users, for here again it was proved conclusively that the bituminous fuels of the Wigan coal-field could be burned with high evaporative efficiency and without smoke emission under steam boilers, if proper attention were given to the design of the furnace, and to the control of the firemen and of the draught. The methods of attaining comparatively smokeless combustion and an evaporative efficiency of 9½lbs. of water per lb. of fuel, in these Wigan trials, were practically those recommended by Williams 29 years earlier, and the chief novelty of Mr. Fletcher's report is the insistance upon the need for good stoking. In his opinion stoking was an art, and should be treated as such, "and not as a slap-dash random process, which any untaught labourer could accomplish."*

The information I have placed before you to-night in my paper, is then merely a restatement, in more scientific form, of the principles and practical recommendations contained in the writings of engineers, who were studying and experimenting upon this subject during the mid-Victorian era. Is it therefore valueless as a practical contribution to the problem of smoke abatement? I think not. There is an altogether mistaken notion abroad that some new theory of combustion or some startlingly new form of steam generator is required before we can hope to reduce the emission of smoke in our factories and centres of manufacturing industry. No greater fallacy has ever entered the minds of engineers, and hindered progress towards reform.

If the principles and methods described by Williams and Fletcher half a century ago, and redescribed by myself in this paper, are recognised and properly carried out, bituminous fuel of the cheapest type can be burned to-day without smoke emission.

The clouds of black smoke which hang about and float away in inky streams from the chimneys of more than half the factories and electric supply stations in this land, are therefore simply an indication of the indifference or ignorance of the engineers who designed and supplied the heating and steam-raising plant.

* William H. Booth in London), F. J. Rowan (in Glasgow), and A. Bement (in America) have since this period been advocating these principles in the technical press.

With a properly designed plant, placed under expert control and manned by properly trained and skilled firemen, smokeless combustion is an assured consequence.

I therefore say that the production of smoke in the cases to which my paper refers is not only a waste of fuel, but is an unnecessary evil, and that it is an anachronism which reflects sadly upon our national want of thoroughness in the application of scientific principles to industrial practice.

DISCUSSION.

The CHAIRMAN, in opening the discussion, was sure all present would agree that the subject was a very important one. He wished, however, the scope of the paper had been wider, for, as the author said, the prevention of smoke in connection with steam raising would merely be a mitigation, to a comparatively small extent, of the evil of general smoke production. It would be acknowledged by all that the author's arguments that every means should be adopted to prevent the production of smoke in cunnection with steam raising were undeniable. He was sorry Mr. Kershaw thought so ill of electric light stations, because he (the Chairman) had hoped that they enjoyed a tolerably good character in regard to smoke production. He did not mean that the entire number of electric light stations, new and old, were equally emaculate, but a very large proportion, especially of the newer and larger stations, deserved some credit for the extent to which they had rid themselves of the opprobrium of smoke production. It was, he agreed, a scandalous thing that, in connection with the production of electricity by refined scientific processes and exquisite machinery, there should be joined the barbarism of smoke production; it was an inconsistency that should not continue. Consideration should perhaps be given to exceptional cases, particularly earlier stations where the site was not well chosen, where the space was a cramped one, and where allowance had not been made for the quantity of power that would be required; but he knew of stations which were very free from any gronnd of complaint on account of smoke production. The author of the paper had been most moderate in his claims; he entirely disclaimed originality in connection with his proposals; but it was by no means a useless thing even to read the Commandments. What Mr. Kershaw had put forward in the paper was very sound science, and he was sure the audience were deeply indebted to him for it.

Mr. RUDOLPH GRUNHUT thought the cause of smoke was often due to the fact that the flues were too small. If bituminous fuel was used the chimneys ought to be designed 10 to 20 per cent. larger than where best Welsh coal was consumed. He had lived for some years in Germany, especially in the industrial district of Düsseldorf, where smoke was practically non-existent owing to the attitude taken up by the authorities. It was possible to prevent smoke, especially where Welsh, Durham, or Yorkshire coal were used. Bituminous coal from Bohemia, which was largely used in Berlin and the surrounding districts, did not create any smoke because the chimneys were large enough. It was found as a rule in this country that the chimneys were not sufficiently high, very few engineers designing chimneys on scientific principles. The great fault was that chimneys were built of about the same diameter at the top and bottom, whereas they ought to be wider at the bottom, because the gases were there hotter and consequently occupied a bigger volume. The present model building laws, which were made in 1812, when chimneys were built very low, and when no big plants existed, were much at fault. That old law made chimney building very expensive, and chimneys were not usually built on scientific principles.

Mr. WALTER REID remarked that the author did not recommend any definite system of preventing the production of smoke, even from coals that were not very bituminous. Very great advance had been made in recent years in the design of plant, the use of automatic stokers being very general. At the St. Louis Exhibition, of 1904 he saw an excellent plant, which produced thousands and thousands of horse-power, and very large quantities of electricity from coal which was not touched from the time it was hewn in the mine, till the time it was consumed. The question whether the firing was intermittent, or the furnace was kept continually hot made a very great difference, and that ought to be considered in the by-laws relating to the subject. Considerable injustice was sometimes done to factories and electric light stations by local authorities in this country, who made no allowance at all for the difficulty of firing up at the beginning of the heating period without any smoke. In France, a certain number of minutes was allowed to get up a heat sufficient to avoid smoke, and after that period smokelessness was the rule. In Germany, the principle was applied in a different way, a certain amount of noxious gases being allowed to be emitted in the course of twenty-four hours. In this country, the gases were allowed to be diluted with air. Manufacturers could practically turn out into the air as much noxious gas as they liked, provided it was diluted below a certain point; but in Germany the total amount of noxious gas that might be emitted was limited, while they did not limit the amount that was to be turned out per cubic metre of gas. He desired to take the opportunity of expressing regret that the firing of large boilers in great power stations was dealt with on such very narrow lines. Inventors were continually inventing new fire bars and new furnaces, but they did not tackle the subject on

broad lines. For instance, in the cement industry enormous quantities of fuel were burned which would otherwise produce a great deal of smoke, but by burning them in rotary kilns an absolutely white smoke was obtained, which chiefly consisted of the fumes from the materials used in the production of the cement and not from the fuel. The fuel in a rotary kiln, if well-handled, produced no black smoke at all. Why such a thing should not be possible with a boiler it was difficult to understand; it was only a question of original design based on the well-known governing laws. One point which the author had not referred to as fully as it might have been was the production of producer gas. There was a slight loss of fuel and efficiency in the production of gas, but, on the other hand, the gain was very great. As the market stood at present, the gain from the by-products was infinitely greater than any loss in the heating efficiency of the fuel. A large Mond gas installation was very remunerative with regard to its by-products; and the whole of the fuel put into such an apparatus could be utilised without producing any black smoke, while at the same time products were recovered which might otherwise go into the atmosphere and pollute it. It must not be considered that because the emission of black smoke into the atmosphere was stopped, that thereby all the impurities which went into the atmosphere were eliminated, because there was always a percentage of sulphur in fuels which went into the air and polluted the atmosphere. The whole key to the prevention or diminution of smoke was the fuller utilisation of the energy contained in the fuel, beeause the more fuel that was burned, naturally the more impurities went into the atmosphere.

Mr. JAMES N. SHOOLBRED said the question of perfect combustion in fuel had been greatly discussed, but it did not make much progress. Appareutly the most ideal method of consumption of fuel was that provided by a very good self-stoking apparatus, but it would be admitted that that was not sufficient. The check in the admission of air to the fuel was very good, but its admission to the chimney had also to be considered, and there the best check to its too rapid progress was a fuel economiser. That was very good arrangement for making use of the heat of the smoke that remained, and so reducing its temperature before admission to the chimney. Another point which was lost sight of was the fact that it reduced the speed, and prevented the smoke from getting too soon into the chimney by the excess of draught carrying with it a quantity of the soot which otherwise was deposited. He quite agreed with Mr. Grunhut as to the necessity for designing the chimney not only for the requirements of the horse-power, but of the particular fuel to be used. In designing a chimney many people seemed to think that the superficial area of the smoke stack was of great importance, but it was the cubical contents of the chimney which were the primary consideration, because the draught was increased or diminished according to the height of the chimney. The cubical contents per horse-power required out of the boiler was the important factor. After consulting many authorities on the subject and as a result of his observations, he found that from three-quarters of a cubic foot to one cubic foot per indicated horse-power was a fair amount to allow with ordinary coal. The temperature at which smoke was allowed to enter the chimney should not be much over 400° F., if it was higher it produced a draught, and where the draught was excessive black smoke resulted. The late Mr. F. W. Webb, of Crewe, introduced rather a novel test for his stokers; he inserted every week a log of pinewood in the chimneys of the engines, and if that was found to be seriously charred at the end of the week the stoker was fined, because he had induced too great a draught, caused probably by the doors of the chimney being opened too often. That rule had had very beneficial effects, at the Crewe Works, in economy in the consumption of fuel, and in the reduction of thewaste into the air. With regard to the remark made about stoking being an art, stokers themselves admitted that the mode in which they stoked made all the difference in the results. He did not know whether the author would bear him out in the remark that self-stoking apparatuses were not so much in favour as they were 20 or 30 years ago, when there was a regular rush for them everywhere. So many disappointments occurred at that time that he fancied a great many of the more recent works were not so ready to adopt any of the numerous patents that were then taken out.

Mr. W. M. MORDEY stated that the author, in explaining the action that took place in the furnace, said that in certain conditions of combustion, hydro-carbon gases passed as a dark brown vapour up the chimney. Was it not the fact that if there were only hydro-carbon gas there would be very little gas smoke? Reference had been made to the difficulties which arose owing to the variation of conditions. The author had given electric light stations due credit for the very difficult conditions under which they had to work. Electric light stations complained of small load factors and very high peaks, which rapidly rose and fell again. Those were conditions as regard smoke prevention which were more difficult than factory conditions, where the load was nearly steady for many hours a day. He agreed with the author that if smoke was formed it must probably be washed; but unfortunately with steam boilers washing meant cooling, and that involved loss of draught. Therefore unless the washing was done at the top of the chimney, it meant providing some other way of getting a draught. The real cure for smoke production was that suggested by one of the speakers, namely, the obtaining of power by gas instead of by steam, and that was bound to come sooner or later. The rivalry between the two was very old, but the issue was cer-

ain. At the present time, with all the steam-raising economical devices and every improvement that could be thonght of in steam plant, only 15 per cent. economy was obtainable, whereas a gas engine could be obtained, without specifying anything in the way of economy, which produced 23 per cent. or 24 per cent. efficiency, and that figure could be increased several per cent. if pains were taken. Although the day of the steam engine and the steam boiler was not over, it would certainly be displaced before many years had passed. He did not think there was a steam-driven station in or near London to-day which had succeeded in giving its customers 4 per cent. of the total energy of the coal consumed; and its importance lay in the fact that the coalfields of this country, at the present rate of output, would approach exhaustion in about 150 years. It must be remembered that the losses were not in the electrical part of the plant or the transmission, as they took place before the transformation into electrical energy He quite agreed with the remark that if smoke were prevented in connection with factories, that would only be a partial cure, because the great sinner in most towns was the open domestic fire. Gas fires, however, were slowly displacing coal fires with very good effects. Gas producers were now being largely used, especially for small industries, and in those cases practically no smoke existed. He did not gather it was suggested that Mond or other gas should be used for firing boilers, because it was fairly well admitted that such gas could not, under most conditions, be used economically in competition with ordinary direct firing.

Dr. H. A. DES VŒUX, after giving particulars of the inception and subsequent working of the Coal Smoke Abatement Society, stated that anyone who had lived in London twenty years or more, could bear testimony to the enormous difference which had been produced in the atmosphere in the last few years; and he had the greatest pleasure in saying that there had been no greater change in any factory in London than there had been in the electric light stations, the smoke from which had been reduced at least 90 per cent. in the last few years. His argument that the smoke from the factories in London had been very much reduced was borne out by the figures published by the Meteorological authorities of the number of days of fog in London, they having been reduced from an average of between 50 and 60 to between 20 and 30 three or four years ago, to 12 the year before last, and according to his own observation to only four last year. About 18 months ago the Coal Smoke Abatement Society sent 72 circular letters to some of the manufactories and electric light stations in London, which had been former offenders against the Smoke Act. Forty-two replies were received, only one of which said that the smokeless combustion of coal had cost them any extra money; thirty-eight said it was an economy, and the remaining two or three said it made no difference in expense. After a great deal of trouble, the Society had started a class for training stokers, which was under the very able superintendence of Mr. Booth, and was attended by over ninety students. That was the first class which had been instituted for the training of the ordinary stoker, and showed what a blank existed in regard to the technical instruction of men who should be partially scientific instead of purely manual labourers. The Education Committee of the London County Council was now being communicated with, in the hope that they would establish similar classes all over London; so that manufacturers would not be able to grumble in the future that they could not obtain properly trained stokers. In reply to the circular which was sent out, the manufacturers also said that, on the whole, they thought efficient hand-stoking was better than mechanical stoking, and that even if mechanical stokers were used trained stokers was also required, while others said they had supplanted their mechanical stokers by manual labour. The Coal Smoke Abatement Society had also endeavoured to start a society in London on the lines of the Hamburg Society, but so far unsuccessfully, probably because there were no engineers connected with the society. They had endeavoured to interest engineers in the subject, but for the last eight years had had to work without an engineer on the committee.

Lieut.-Col. ALLAN CUNNINGHAM, R.E., desired to re-inforce the remarks which had been made as to the improvement in the climate of London. His memory carried him back 55 years ago, when factories used to freely emit large volumes of black smoke; but things had very much changed since then. A great change had taken place in the climate of London. Fifty-five years ago a London fog was of a yellow colour, at the level of the street; it was of an intensely acrid character, and entirely stopped traffic. While the black smoke emitted by factories had decreased, there had been a vast increase in the amount of smoke sent out by domestic chimneys, and that had caused a change from the yellow fog of old days to the black gloom overhead of which the London fog now consisted.

Dr. OWENS inquired whether the author had any data as to the percentage of fuel which was lost in solid carbon from factory chimneys, and in tar and unburnt hydrocarbon gases? He believed that the loss from domestic grates sometimes approached 5 per cent. of the total weight of the fuel burned; but he knew that in factory chimneys and well-fired furnaces the losses were not more than about one-third per cent. There could be no doubt as to the diminution that had taken place in the number of fogs, and further than that, the drop occurred in the year 1900, the very year that the Coal Smoke Abatement Society commenced its work. He did not wish to criticise anything the author had said as to the principles of

combustion, but thought the problem should be looked to as a whole and not in part. It was useless only to consider factories, because the solution for them might leave unsolved the solution to the other part. If a solution was to be looked for in the form of gas delivered into large cities, that would do away entirely with the production of steam in boilers.

Dr. SCOTT TEBB stated that he was analyst to one of the metropolitan boroughs, aud that in his experience there did not seem to be in recent years any diminution in the number of complaints with regard to smoke brought to the notice of the Council. He desired to raise the point whether the diminution in the fogs of London was altogether concerned with the question of coal or smoke. It seemed to him that meteorological conditions might exist in connection with the mistiness of the air which might produce the fogs.

Mr. WALTER C. HANCOCK emphasised the last speaker's remarks that it was necessary to take into consideration, in connection with the question of the reduction in the number of fogs in London, any changes which might have taken place in the meteorological conditions that had prevailed in London during past years. The reduction in the number of fogs had extended over a small period, and it was hardly safe to draw inferences from the results of a few years. The fact that there had been such a rapid advance in the application of gas and electricity of recent years must be taken into consideration in dealing with the question, while the humidity of the atmosphere was also a very important factor. He also agreed with the statement that the question must be considered as a whole, and that the most important factor in the creation of smoke in large cities, was the domestic chimneys. There was no doubt as to the economy to be obtained in the smoke production of an ordinary factory chimney by the proper construction of the chimney, by the regulation of the air, by mechanical stoking, and the introduction of economisers.

Mr. F. H. SMITH suggested that the question of the relative merits of mechanical and hand stoking depended entirely on the quality of coal used. One speaker had suggested that, in order to avoid smoke, a very important point to take into consideration was the design of the chimney, and he went on to argue that the cubic contents of the chimney was the important consideration. In his opinion, it did not depend on the cubical contents of the chimney.

Mr. KERSHAW, in reply, stated that the first speaker emphasised in the remarks he made with regard to the width and height of the chimney and the design of the plant generally adopted in Germany what he himself had stated in the paper, that the design of the plant and especially the size of the furnace, the boiler, and the combustion chamber ought to be carried out in view of the kind of fuel that was to be burnt. As a rule, plant was planked down without any reference to the coal that was to be burnt in it, and in nine cases out of ten difficulties arose because the combustion chamber was too small, while on other occasions bituminous fuel was burnt instead of Welsh coal. The remarks made supported his own view, that bad design of plant was in many cases the cause of the trouble. With regard to the question of draught, he thought it would be found in the best generating stations that induced or artificial draught was used in place of natural draught, which gave greater command over the work which could be obtained. If artificial draught was used in electric light plant, it was possible to adapt the plant to the lead on that station, whereas if natural draught was employed the engineer was handicapped. Mr. Reid, who agreed with most of the principles laid down in the paper, had rather quarrelled with him because he had not given more details as to the practical applications of the principles advocated. His reasons for not doing so were obvious. There were hundreds of patented applications of the principles on the market, in the validity of which he did not much believe, but it would have been impossible for him to describe them all in the space at his disposal. He, therefore, thought it much safer just to describe the general principles, and to treat the application of them in the way he had done, rather than by describing particular patents. Mr. Reid also referred to the use of coal-dust for firing cement works. The Schwartzkop coal system had been applied to the firing of boilers, and another system was also being used, which had not been generally adopted because of the great difficulty of grinding the coal. The whole of the district round about where the system was used was plastered with coal dust; and for that reason he believed coal dust firing had not advanced much, although it solved the difficulties which had arisen. Gas had been applied to boiler firing as a kind of intermediate stage. At one place a Mond gas plant was put down some years ago, the gas being used for firing the boilers; a complete transformation had now taken place, gas plant alone being used. Gas firing could be applied, and did, to some extent, overcome the difficulties experienced. Mr. Shoolbred, who dealt with the defects of mechanical stokers and the need for economisers, did not mention one great difficulty with mechanical stokers, viz., that where travelling chain grate stokers were used, the back of the grate became choked up with unburnt coal, a great deal of the fuel being lost, or open spaces were left through which a lot of air entered. Personally he believed that mechanical stokers, when well managed by a good stoker, did give high efficiency, but it was a question of management. He thought that Mr. Mordey, who asked a question about the hydrocarbon gases, was in error in stating that if they were in a pure state they would not be colourless. Hydro-

carbon gases in the pure state were colourless, but as they were generated from coal they were mixed with tarry vapours which gave them a colour. Mr. Mordey was also incorrect in thinking that the colour could be entirely got rid of if the solid particles were washed out. From the results of his own observations in testing a large number of coals, he did not think that colour was due to solid particles. He quite agreed with Mr. Mordey that ultimately gas engines would be generally adopted; their efficiency was so much higher, that there seemed to be no reason why that should not be so, but it would be a very long time before it would be possible to scrap all the steam generating plant in this country, and substitute gas engines for it. His paper dealt with things as they existed at present, and how smoke that was produced by steam-generating plant could be prevented. As a member of the London Smoke Abatement Society, he was greatly interested in the work it had done, and was glad to hear from Dr. Des Voeux that so much of the improvement in the atmosphere of London was due to their work. Colonel Cunningham had referred to the improvement in the atmosphere of London in the last fifty years, but other speakers seemed to think it had not improved so much as Colonel Cunningham thought. There was not much definite data available with regard to the fuel actually lost in smoke and hydrocarbon gas escaping from factory chimneys. He thought it was a good deal more than the one-third per cent. estimated by Dr. Owens, but he was sorry he could not give actual figures. Wherever black smoke occurred, bad conditions of combustion existed which led to the loss mentioned, the amount of heat lost amounting possibly to 30 or 40 per cent. of the total heat value of the fuel. In conclusion, he desired on behalf of the audience and himself to thank Sir Joseph Swan for so kindly presiding over the meeting.

The CHAIRMAN, in proposing a hearty vote of thanks to Mr. Kershaw for his interesting paper, said he was exceedingly gratified that so many of the speakers had testified to the improvement which had taken place in regard to the non-production of smoke at electric light stations. It must not be forgotten that the electrical engineer had to labour under considerable difficulties in connection with the production of power for the generation of electricity, owing to the irregularity of the demand. Sometimes he had to maintain boilers under steam when there was no demand, while at other times he was suddenly called upon to develop a large amount of power. If any of the proposed great schemes for the generation of electricity, more particularly with a view to the production of power in place of steam, were ever carried out, as he had no doubt they would be, they would constitute a very important contribution to the means of further abating smoke arising from works not only in connection with the generation of electricity for lighting, but also through the substitution of the steam engine by electrically produced power, and the equalising of the demand.

The resolution of thanks having been carried unanimously, the meeting terminated.

FRENCH CIDER PRODUCTION.

The manufacture of cider in France has assumed enormous proportions, and in some parts of the country, especially in the north, its consumption exceeds that of wine. It appears that the cider production of 1906 amounted to 477 million gallons, against 88 millions in 1905. It used to be said that the cider output was usually about one-fifth that of wine, but in 1906 it was considerably more than a third. The American Consul at Bordeaux says that while there are over eighty varieties of apples grown, he finds that but thirteen of them are ever used for making cider. These are the "Marin," "Onfroy," "Grosbois," "Bedan," "Blanc Mollet," "Railé," "Fréquin Blanc," "Fréquin Rouge," "Jaune et Pointu," "St. Laurent," "Martin Tessart," "Prune de Miel," and "Argile." It is said that sweet apples make a flat cider, difficult to keep, and lacking in alcohol. Cider made from bitter apples is poor, thick and astringent, and sour apples make an acid cider which is considered injurious to the digestive organs. The best apples for cider making are those which contain sufficient sugar and tannin, and which have a pleasant fragrance. These qualities, the varieties named, especially the first three, possess in a remarkable degree. Many of the manufacturers claim that a mixture of one-third of sweet apples to two-thirds of bitter and sour apples makes the ideal cider. The apples are gathered only during fine weather. They are shaken from the trees and caught in nets to prevent bruising or contact with the ground. If they are not carried immediately to the press they are placed in dry lofts where there is a good circulation of air ready for use. The idea that fermentation purges of all impurities is not believed in France, at least so far as cider making is concerned. No green, decayed, or worm-eaten apples are ever used. The fruit must be clean, for even a little particle of earth, it is asserted, will produce a chemical action that is highly injurious. The fruit is first put through a cutter, the pulp and juice collected in a vat and exposed to the air for about fifteen hours, being stirred from time to time. The pulp is then put in the press, in layers of from four to six inches, separated by light rush screens, and the juice extracted. At this first pressing, the best of the modern presses (the old cumbrous affairs having almost entirely disappeared), give no more than 65 to 70 per cent. of pure juice. The "must" from the first pressing is placed in a vat, warm water being added to the extent of 25 to 30 per cent. of its volume. It is left to macerate for about fifteen hours and then pressed a second time. To the remaining must there

are added ten gallons of water to every hundred pounds, and then comes the third pressing. One hundred pounds of apples are said to yield of first quality pure cider, 60 to 70 pounds; of second quality cider, 25 to 28 pounds, and of third quality cider, 25 to 28 pounds. In some places cider is made by the method of diffusion, which consists of macerating finely chopped apples for twenty-four hours with an equal quantity of water. The process is repeated three times, but it has been said that the results are not nearly so satisfactory as the method previously indicated. Cider is fermented in closed apartments with a temperature of from 54° to 65° Fahrenheit. The casks in which it is to ferment are thoroughly cleansed, and the sulphur wick is burned in them. In the fermentation, the lighter substances called the "chapeau," rise to the surface, and the heavier—the lees, which are thick and sticky—fall to the bottom. Between the two is the pure cider. If the fermentation is not sufficiently active it is usually increased by taking out and heating one-fourth of the contents of the cask and then pouring back over the rest. After fermentation (in from four to five days, if the temperature is moderate, a little later if cold), the cider is drawn off carefully into sulphured casks, which are always kept well filled. Two months later it is again racked, and six weeks later drawn off for the third time. The liquid is then generally perfectly clear, but if not it is clarified with about two ounces of tannin for every hectolitre (22 imperial gallons). Cider is best preserved in cool, dry cellars, and in bottles better than in casks. Thick champagne bottles are always used, and the corks are tied with twine. Rubber stoppers are never used for cider bottles. If bottled fresh the cider becomes sparkling. If it is found to be slightly acid, a little candied sugar is added to each bottle. Three months afterwards the cider becomes excellent. Cider frequently turns bad, especially if every stage of its manufacture has not been well looked after, and carefully done. Among the principal "maladies" to which cider is subject may be mentioned the "Fleur du cidre." This is a sort of white veil floating in the cider. As soon as it is noticed the liquid is drawn off into a clean cask, recently sulphured. Acidity, when the cider is turning into vinegar, is corrected by pouring into the cask a small quantity of good olive oil, and, if necessary, a little neutral tartrate of potash or powdered lime or chalk is added. Bitterness is corrected by adding sugar and tannin. Greasy cider occurs when it becomes sticky and greasy, and flows like oil. It is remedied by adding tannin dissolved in water.

THE MINING INDUSTRIES OF CUBA.

The development of mining in Cuba may be said to date from 1830, when companies were formed for working the copper mines in the province of the Oriente. During the nineteen years following, there were exported more than 600,000 tons of copper, and this only from two mines, the Consolidada and San José. Subsequent to the paralysation caused by the first war of independence (1868), and as a result of the demand for minerals, the spirit of enterprise was stimulated, with the result that numerous copper and iron mines were discovered and worked in Oriente. Soon after, manganese mines were discovered in the same province, and naphtha, gold, and copper in Santa Clara. A revival of the industry took place immediately after peace was restored in 1899, a good deal of prospecting being done in the province of Pinar del Rio, where it appears that coal mines exist. It is also believed that asphalt and copper mines are to be found in that province, and in Habana and Matanzas. According to the American Consul at Cienfuegos, there is not sufficient knowledge of the real mineral resources of the island to make an accurate estimate. The mineral resources are represented by the following products:—Gold, silver, iron, copper, manganese, lead, asphalt, petroleum, naphtha, graphite, amianthus, asbestos, zinc, mercury and coal. These minerals are found in most of the provinces, but the richest district is the province of Oriente, followed in importance by Santa Clara, Camaguey, Pinar del Rio, Matanzas and Hobana. The total number of mines surveyed and the boundaries marked in the island up to December 31, 1905, was 386, containing 51,550 acres, divided among the provinces and classified as follows:—Asphalt, 78; copper, 77; iron, 63; pit coal, 11; oxide of red lead, 1; manganese, 84; gold, 13; graphite, 2; lead, 5; zinc, 2; asbestos, 1; other kinds, 49; making a total of 386. The total area of the mining districts of Cuba is 56,395 acres, of which 44,586 belong to the province of Oriente, 4,288 acres to Santa Clara, 5,202 to Camaguey, 1,361 to Pinar del Rio, 444 to Matanzas, and 514 to Hobana. Of the above number of mines, very few of iron, manganese, and copper, in the province of Oriente, are in operation. The others can be considered only in concessions waiting for funds for exploitation. The administration, according to the laws in force, cannot compel the miners to work their claims. The owner is in possession of his mine in perpetuity, and at his own will may work it or not. The only cause of forfeiture established by the law is the failure to pay the annual taxes. The applicants for mines can, according to law, ask for one, or several claims at the same time. A claim, or "pertenencia" as it is called, is 984 feet long by 656 feet wide, except when the mines are of iron, coal, anthracite, lignite, turf, asphalt, or bituminous clays, when the pertenencia is 1,640 feet long, and 984 feet wide. The taxes to be paid to the Government are twenty shillings yearly for every 2½ acres, when the mines are of precious stones or metalliferous substances. In the other cases the tax is eight shillings for every 2½ acres. The annual production of the mines actually worked is valued at £300,000.

HOME INDUSTRIES.

Mining in Cornwall.—Attention has been directed more than once in these notes to the probable effect of the great rise in the price of metals upon mining in Cornwall. It was reasonable to assume that tin mines shut down when tin was at a price that left only small profit to the richest mines would be re-opened now that tin is quoted at record rates, and that improved machinery and more modern methods of working would be introduced. But the Cornish miner looks aghast at innovation. He has no objection to the outside capital necessary to extend the workings, it is outside methods and management to which he objects. Engineering firms that have examined the existing plants with the object of inducing the adoption of more economical appliances for pumping, &c., have not met with much encouragement. And the explanation is not far to seek. As Mr. H. A. Le Feuvre points out in an interesting communication to the *Times*, quoted here, Cornish mining has largely remained a local industry, into which the eastern engineer, the manufacturer of mining industry plant, and tools, and the purveyor of stores, had little chance of entering. The only way to break the local monopoly was to obtain control of properties for the purpose of exploiting mines, and this has now been done to some extent, and will probably be done to a larger extent in the near future. The Cornish mining industry is being decentralised and recentralised in London, to the probable great benefit of the engineers, and the mining machinery manufacturers. Is it possible for Cornwall to regain the position as a tin producer she lost many years ago. At the beginning of the last century, Cornwall produced more tin than any other country in the world, to-day four other countries are larger producers. Is the loss of position due to the lack of mineral reserves? The popular impression is that the tin mines of Cornwall are now worked at such a depth that the cost makes profitable working difficult where it is not impossible, that the tin mining industry of Cornwall is now in the position the Transvaal gold mining industry is expected to be in fifty years hence. But this would seem to be a very erroneous view of the position. Only one mine in the country has yet reached the depth of 3,000 feet, and there it has a lode as productive as any in its history of a hundred and fifty years. Of the hundreds of abandoned mines, Mr. Le Feuvre puts the average depth at less than 800 feet, and apart from them there are vast tracks which have never yet known the prospector's pick. In Mr. Le Feuvre's opinion there is in the West of England a vast field for metalliferous enterprise, and this view is that of other competent examiners. Capitalists are coming round to this view, and it may be that before long invention and enterprise may restore Cornwall to its old position in the mining world.

Employers' Liability Insurance.—The Employers' Liability Insurance Companies Bill now before the House of Commons, and which has been introduced on behalf of the Board of Trade, supported by the Home Office, will, if it becomes law, have an important bearing upon employers' liability insurance business. Its principal clause extends the application of the Life Assurance Acts, 1870-72, which require a deposit of £20,000, and the submission to the Board of Trade of annual accounts and periodical valuation statements on prescribed forms, to "every company, whether established before or after the passing of this Act, which carries on within the United Kingdom the business of insuring employers against liability to pay compensation or damage to workmen in their employment, subject to such necessary modifications and adaptations as may be made therein by Orders in Council." Companies transacting employers' liability insurance business before the commencement of the proposed Act which shall prove to the satisfaction of the Board of Trade that the funds set apart and assured for the satisfaction of claims of employers amount to £40,000, and others which have already made a deposit under the Life Assurance Companies Acts, are exempted from the provisions of the proposed Act. It will not, therefore, affect large insurance companies which have been transacting workmen's compensation business. The Bill is aimed rather at small accident companies, which are springing up in considerable numbers, but which will be severely weeded out if they have to make a deposit of £20,000. It is very desirable that companies of this class, without the necessary capital to insure the fulfilment of obligations, shall disappear, but the Bill, if it passes, will still further concentrate insurance business into a comparatively few hands. This process of concentration has been going on for some time past, and it is by no means at an end—the proposed sale of the business of the Central Insurance Company to the Liverpool and London and Globe being the latest indication of it—and it is viewed with something like uneasiness by those who are anxious to avoid anything like a monopoly or "ring" in the insurance world. The public have to be protected against mushroom insurance companies, but wholesome competition is also necessary to prevent inequitable rates and conditions.

A Small Duty on Coal.—Many are likely to think that a good deal can be said in favour of Mr. James Syke's suggestion of a small duty per ton on all coal raised. On last year's output a penny per ton would yield over a million sterling. The money would be easily collected, and the tax being added all round to the cost of production, its incidence would be borne by every class in the country, with far more equity, as Mr. Sykes contends, than many other taxes existing or proposed. There would, of course, be a demand for rebate on exportation (which would reduce the yield by about one-fifth), and Mr. Sykes recognises that this would be "considered by some a highly objectionable reversal of the policy just abandoned." The Chancellor of the Exchequer is not likely to adopt the suggestion, but it invites discussion.

Wool Supplies and Prices.—The outlook for the wool grower continues very bright. Values of every quality of wool are considerably higher than at any time during recent years. The following figures are interesting:—

	70's	64's	60's	50's	40's
	d.	d.	d.	d.	d.
1899	25	24	23	15½	10
1902	21½	21	20½	11¾	8¼
1906	27½	26¾	26½	21½	16½
1907	29½	28½	27½	22½	17¾

The price of every quality of wool is higher, with one exception, and this notwithstanding exceptional supplies. Not for more than ten years has trade in Bradford been so busy as it is now. Consumption is believed to be upon a larger scale than ever, and high prices have forced a lot of trade on to cotton. Even in hosiery yarns, cotton and wool are now twisted with quite acquired ingenuity. And in the dress goods trade, says the Bradford correspondent of the *Economist*, fabrics are lighter in weight, and yarns of finer counts are required. Hence, although spinning machinery is engaged to its utmost capacity, the quantity of wool passing through is probably less. It is certainly very much less per spindle than it was a few years ago. There is little likelihood of values receding notwithstanding the large supplies.

Cotton.—The American crop results are very surprising. During the last month there has been an enormous volume of cotton pouring into sight. Whilst a falling off was expected with the advent of March, the contrary has been the case. The total crop brought to light to 8th March was 11,497,000 bales, as against 9,028,000 bales for the corresponding period of last year, and 9,992,000 for 1904-5. Messrs. Neill Brothers had estimated a total of 13,500,000 bales, and notwithstanding the latest figures they adhere to that estimate, although, if deliveries continue on the same level as in 1905, there will be a crop of something like 15,000,000 bales. The visible supply for the world on March 8th of American cotton only was 4,036,000 bales, as against 3,404,000 bales on the same date last year, and 2,989,000 bales in 1905, whilst all sorts amounted to 4,712,000 bales, as against 4,032,000 in 1906, and 3,458,000 in 1905. Great Britain has taken 1,844,000 as against 1,665,000 bales, the Continent 2,615,000 as against 2,107,000 bales, and Mexico, Japan, &c., 151,000 as against 82,000 bales, leaving 3,548,000 as against 3,260,000 bales for the United States and Canada. With more than five months yet to be accounted for, the cotton crop is two and a-half million bales above the parallel figures of last year, and one and a-half million bales ahead of the parallel figures of 1904-5. The quotation for middling American cotton has dropped to 6d. per lb., comparing with 5·77d. per lb. a year ago, and 4·31d. in 1905.

Canal Haulage.—The application of electrical power for haulage is making some headway on canals. The latest instance is on the new canal which connects the Havel and the Spree. This canal is about twenty-five miles long, and has cost over £2,000,000 to construct. It runs partly through a series of lakes, but on the other sections of the waterway a tow-path is laid on both banks, at an average level of five feet above that of the water. The method of haulage adopted on the canal (after a series of comparative tests) is described by Professor E. W. Marchant, writing in the *Times*, as one in which tractors, running on a light railway on the tow-path, haul the barges along, current being collected from an overhead wire by a bow collector, specially designed to give a large range of vertical movement, and returning by the rails, which are, of course, bonded. An interesting feature in connection with the Teltow installation is the complete centralisation of power that has been effected. Everything in connection with the canal is electrically operated. "The lock-gates at Kleine Machnow (which are of the portcullis type) are worked by inductive motors fed from the central station; the capstans at the locks, the special lock locomotives, and the cranes at the various landing stages along the canal brink, are all driven by motor power."

Shipbuilding at Preston.—Whilst shipbuilding elsewhere has been exceptionally active, it seems very likely to die out at Preston, if it may not be said to be already dead. Thirty years ago Mr. Allsupp opened a shipyard on the Ribble, which he conducted in a small way up to a year or two ago, when it was taken over by the Caledonian Shipbuilding Company, but it was found impossible to make the yard pay. Many of the men were discharged, and new orders were not sought. An attempt was made to sell the yard as a going concern, but a purchaser has not been found, and it is expected that it will soon be closed. The shallowness of the river makes it impossible to build large craft, and there was never any likelihood of Preston becoming the seat of an important shipbuilding industry. It is indeed a little surprising that the attempt was ever made to create such an industry there.

GENERAL NOTES.

Ecuador.—In his last year's report upon the trade of Ecuador, Mr. Consul Cartwright referred to the progress of the Guayaquil and Quito Railway Company, and in his report just issued (Cd. 2383) he says that the date at which the conclusion to Quito will be fulfilled is very doubtful. The project of a railway to Curaray (Amazon district) has been open to competition by tender, and the attention of the Government has been given to the cart road from Papallacta to Baeza. Imports from the United Kingdom remain larger than those of any other country, but the difference between them and the United States is very slight, Germany being third.

ABYSSINIAN COFFEE. — In his report upon the trade of Abyssinia (Cd. 3283), Mr. Vice-Consul Johnstone directs attention to Harrari coffee, which is cultivated with great care round the town from which it takes its name. It is known on the London market as "Long Berry Mocha." A large proportion of the harvest finds its way to Aden, where it is mixed with Yemen coffee for export. "Abyssinian" coffee comes from the south-west provinces of the country. The forests in which it flourishes are the property of the District Governments. The nobles and officials are allotted a share of the harvest according to their rank. The poorer inhabitants cultivate the plant, though they do not produce a difference appreciable from the berry of the wild shrub. The coffee is pronounced to be of good quality, but since it is shaken off the shrub and then picked off the ground, it loses a certain amount of its aroma in the process. The quantity passing through Adis Ababa every year is said to amount to from the value of 200,000 to 300,000 dollars. The export of Abyssinian coffee seems now, to a great extent, to have been diverted to the Nile, it being estimated that as much as two-thirds of the total amount leaves Abyssynia by that route.

TEA EXPORTS TO AMERICA. — The North American market is becoming a very important outlet for Indian and Ceylon teas. The rapid growth of this market is shown in the tables compiled by Messrs. Gow, Wilson and Stanton, and to be found in their weekly circular. In 1901, the Indian tea taken to North America amounted to 6,960,000 lbs., and with a trifling set-back in 1903, the import has continuously increased, the import for 1906 being no less than 17,653,851 lbs.; and with Ceylon tea, the increase has been almost as great. In 1900, Ceylon exported to North America 8,495,288 lbs., and with the exception of 1904 and 1905—in the latter year, the export fell to 18,998,373 lbs.—the growth has been continuous, the export for last year amounting to 22,769,875 lbs. In 1906, the North American market took practically a quarter of the whole quantity of Indian and Ceylon teas used outside the United Kingdom, viz., forty millions, against thirty-two millions in 1905. In 1900, the quantity taken, as stated above, was only fifteen million lbs. Not a little of this increase may be attributed to the steps taken in India and Ceylon to make their teas better known in America.

THE NEW HEBRIDES.—The recent discussions in Parliament and elsewhere upon the New Hebrides will cause the report of the Resident Deputy-Commissioner (Cd. 3289) just issued to be read with unusual interest. A good deal has been made in discussions upon the Anglo-French Convention of the fact that two-thirds of the present white population are French, as against one third English, but Captain Rason shows that this French numerical snperiority is only of very recent date, and is due to other than normal increase. At the end of 1900 the French settlers numbered 182 as against 167 British. During 1901 the French made every endeavour to increase their settlers, with the result that at the end of that year they numbered 293 as against the same number of British settlers as formerly. Then the Commonwealth tried to increase the number of British settlers, and brought the total up to 217, but the French in the meantime had increased to 401, and by the end of 1905 the numbers stood at 225 British and 417 French, the population to-day being practically the same. Captain Rason says that the French Government has been much more liberal in its treatment of French settlers than the British Government dealing with British settlers. These latter have suffered especially from the high duties in Australia upon maize. These duties were imposed almost immediately after the creation of the Dominion, and amount to 35 per cent., the result being that little or nothing is now left to support the British planter whilst his cocoanut trees or coffee is maturing. The freight upon maize to Sydney has been reduced from the prohibitive rate of £2 per ton to 7s. 6d. per ton, which makes it possible to send one crop of maize to Sydney a year. But the New Hebrides planter gets no profit from the price obtained. The average cost of shipping a sack of maize to Sydney, including all charges, is 6s. 6d.; the average market value of maize in Sydney is 10s. to 11s., leaving 3s. 6d. to 4s. 6d. gain to the grower—and it costs 4s. to grow a sack of maize.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 25...Farmers' Club, Whitehall Rooms, Hotel Metropole, S.W., 4 p.m. Mr. A. D. Hall, "Agricultural Education and the Farmer's Son."

Geographical, University of London, Burlington-gardens, W., 8½ p.m. Mr. W. Rickmer Rickmers, "Photographic Report of a Journey through the Highlands of Duab (Zarafshan, &c.)."

Actuaries, Staples-inn-hall, Holborn, 5 p.m.

Medical, 11, Chandos-street, W., 8½ p.m.

TUESDAY, MARCH 26...Asiatic, 22, Albemarle-street, W., 4 p.m., Mrs. W. R. Rickmers "Scenery, Cities, and People of Western Turkestan."

Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. Mr. Moses Kellow, "The Application of Hydro-Electric Power to Slate Mining." 2. Mr. A. H. Preece, "Electrically Driven Winding Gear and the Supply of Power to Mines."

WEDNESDAY, MARCH 27...Geological, Burlington-house, W., 8 p.m.

United Service Institution, Whitehall, S.W., 3 p.m. Col. H. B. Jeffreys, "The Native Races of South Africa from a Military Point of View."

Royal Society of Literature, 20, Hanover-square, W., 8½ p.m.

British Astronomical, Sion College, Victoria-embankment, E.C., 5 p.m.

CORRECTION.—Indian Railways, *Journal* p. 462, col. 2, ll. 20-21, should read "the average mileage per locomotive of all classes per annum is 27,124," and ll. 26-27 "the goods vehicles number 11,566, these having an average daily mileage of 63 miles."

Journal of the Society of Arts.

No. 2,836. VOL. LV.

FRIDAY, MARCH 29, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

LIST OF MEMBERS RESIDING ABROAD.

Lists of members resident abroad have been prepared, and can be obtained by members on application to the Secretary.

The following lists have been printed:—

1. Members resident in India, Persia, China, Japan, the Malay Archipelago, &c.
2. Members resident in Africa.
3. Members resident in Australia, New Zealand, Tasmania, and Polynesia.
4. Members resident in the Dominion of Canada and Newfoundland.
5. Members resident in the United States of America.
6. Members resident in South and Central America, Mexico, and the West Indies.
7. Members resident on the Continent of Europe.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

Thursday afternoon, March 14; LORD AMPTHILL, G.C.S.I., G.C.I.E., in the chair.

The CHAIRMAN, in introducing the reader of the paper, said that Sir James Thomson was lately a Member of the Council of Madras. He thought he should not be considered impertinent in presuming that a proportion of the audience had not a clear idea of what the term "Member of Council, Madras," meant, and he would endeavour to explain it in a few words. That part of India which was designated as the Madras Presidency was a country larger in area than the British Islands, and contained a greater population than that of the United Kingdom and Ireland. That very large portion of His Majesty's dominions was governed, subject to the higher authority of the Government of India and the supreme control of the Imperial Government, by a triumvirate, officially known as the Governor in Council. The Governor, who was invariably appointed from the ranks of public men in this country, was assisted by two senior members of the Indian Civil Service, who were his colleagues and were known as Members of Council. It would be seen that the position of Member of Council was one of very great power and responsibility. The Council consisting of three, it would be realised at once that the Governor could be easily put in a minority, and that he could do nothing without the consent of at least one of his colleagues. That was the position to which the author attained after thirty years of service in India. Those present would understand that it was not by mere seniority that Sir James reached that position, and that he had for a time held an even higher office, namely, that of Governor of Madras. If anything had been seriously wrong with the Government of Madras, either during the period when Sir James was at the head of it, or during the longer period, when he was one of what might be called the Cabinet of the Madras Government, something would have been heard about it in this country. Recent experiences amply illustrated the truth, that the men who were responsible for the administration of different parts of the Indian Empire, and for the permanent conduct of affairs in the great departments of State in that country, only became known to the great British public when something went wrong. It might, therefore, be assumed that, as the author's name had not been prominently before the British public during the time of his service in India, he was, at any rate, not responsible for any serious mishap. His own feelings towards Sir James were a matter he could not intrude upon the audience. Those present would realise that when one had worked with a man in perfect harmony and unbroken friendship for a number of years at concerns of such great importance and interest, it was impossible to feel otherwise than grateful and affectionate towards him. Those were his feelings towards Sir James Thomson, whom he had much pleasure in calling upon to read his paper on the city of Madras, a part of the world which was dearer to them both than any other city they knew.

The paper read was—

THE CITY OF MADRAS.

By Sir James Thomson, K.C.S.I., LL.D.,
Late Member of Council, Madras.

A brief foreword is necessary by way of explanation and apology. I undertook this paper with considerable reluctance, for I have no special knowledge of the subject, but I felt that the city which welcomed me to India thirty-five years ago was in some disregard, and, since more competent spokesmen refrained, that I ought to do what I could for her appreciation. Madras has been my headquarters for only a part of the last eight years, and when there the work of the day left no leisure for inquiries of the present sort. Of current social and municipal life I was necessarily more or less aware; of the past beyond the main facts I confess myself only a student. And now, on this side of the world, I am unable to verify many points that suggest themselves, and I despair of setting before you in the brief time at our disposal any duly-proportioned account of what Madras has been and is on her two hundred and fifty years of existence.

I should first indicate the sources of information for the benefit of whoever wishes to be informed further. Mr. Talboys Wheeler, as a consequence of his appointment, in 1860, by the Madras Government to report on the character and value of the records in the Government-office, was enabled to produce in 1861 the papers afterwards collected and issued under the title, "Madras in the Olden Time," which exhibit the history of the Presidency from 1639 to 1748, and are a storehouse of information for that period to all who come after. The Madras records, however, were defective till 1670, and in 1902 Mr. Foster supplied the information regarding the "Founding of Fort St. George," which was available from the records of the India Office. Mrs. Penny's "Fort St. George," a vivacious and most readable if somewhat discursive volume, was issued in 1900; Mr. Leighton's "Vicissitudes" in 1902, so interesting in personal details and so clearly presented that it is to be regretted that he has not carried his work beyond 1798. Colonel Love, in describing the pictures in Government House and the Banqueting Hall in 1903, has at the same time with great care and accuracy set out the history of the Fort and other connected matters; and Mr. Penny in 1904 produced "The Church in Madras in the Seventeenth and Eighteenth Centuries" with minuteness, and correlated with general history in a very useful manner. Sir Charles Lawson's "Memories," published in 1905, give a deal of information regarding persons and families. Besides general histories, much may be learned from the lives of individual worthies and the notes and writings of visitors and sojourners. My chief difficulty has been to find any comprehensive survey of the nineteenth century: it is the earlier history that has had fascination for narrators; the quietude and even tenour of later days attract no chronicler with an eye to effect, and are no doubt dry-as-dust to all but a few.

Between the beginning of the century and 1639, the East India Company had established trading depots or factories at Bantam in Java, at Surat on the West Coast, and at Masulipatam, Nizampatam, and Armeghon, on the Coromandel Coast of India, and were maintaining an unequal rivalry with the Dutch, who were firmly seated at Pulicat, possessed of greater resources, and with a firmer hold and greater experience of the markets in the exchange of precious metals and broadcloth for the silks, chintzes, precious stones, and spices, which were coveted in the West. The Portuguese at San Thomé were in decadence. The native authorities in that part of the country which contained Pulicat and San Thomé, relicts of the Empire of Vizianagar, whose headquarters were at Chendragiri, had evidently a sense of the value of competition in trade, and invited the settlement of the English. They accordingly moved from Masulipatam to Armeghon in 1626. There they found themselves no better off than at Masulipatam, and returned thither six years later, but kept up Armeghon on a reduced scale. It was an impossible and naturally "unprofitable" place for the company's purposes, as any one who has seen it even at the present day would understand, and the directors, in 1638 or 1639, ordered its abandonment. The Nayak—the local officer under Chendragiri—renewing his advances towards friendly relations, Mr. Francis Day, then chief, set out in 1639 to negociate, and was so taken with the quality and prices of the cloth specimens shown him at Madraspatam compared with those of Armeghon, that he became instant for settlement, and obtained a *firman* or grant from the Nayak. The copy thereof recites that Day had, on solicitation, repaired to "our port of Madraspatam" and held conferences, and the Nayak, out of special love and favour for the English, had granted to him or those in

his place power to direct and order the building of a fort or castle in or about Madraspatam, and full power and authority to govern and dispose of the government of Madraspatam for two years after it was fully occupied, and thereafter to receive half the custom and revenues of the port. The Company were to be duty-free on their imports and exports there for all time, and to pay only half duty on goods transported up into or through the Nayak's country, to have a perpetual free grant of minting and the Nayak as surety for their trading advances to approved persons, to be exempt from duty in respect of provisions bought in the Nayak's country for their fort and ships, and to have restitution of all shipping of the port that suffered wreck.

The factors at Masulipatam had full comprehension of the benefits conveyed, but the sanction of Bantam was necessary, expenditure was involved, and money was not a ready commodity then. They reported accordingly, and also to the Company, setting out the advantages of the place, the second of which was "the whole benefit of a town near by for two years, which town may be, at present, worth about 2,000 pagodas per annum." One seeks vainly for that town, and must conclude that Day was a very sanguine person even in the conditional mood. He was sent with borrowed funds to accomplish the removal from Armeghon to Madraspatam. The headship of local affairs was, meantime, transferred from Bantam to Surat, and the authorities of Surat, in December, gave a half-hearted acceptance to the project. Andrew Cogan had become chief at Masulipatam, and along with Day set to build the fort in 1640, but the money difficulty continued and the necessity of a fort had to be impressed on the Company in this wise: "It hath been a continued tenet among as many of your servants as have been employed in these parts that goods, especially paintings (*i.e.*, prints, chintzes), cannot be procured nor secured when acquired unless you have some place of your own to protect the workmen from the frequent enforcements of those tyrannous governors, and to lodge your goods free of the mischievous attempts which those treacherous Gentues or inhabitants of that country are too often ready to adfer against them;" and accordingly, and for their own reputation, the erection of the fort should proceed as it was now in good forwardness, and 300 or 400 families of weavers, painters, and other artificers had come to live under their protection.

Cogan made Madras the chief factory, and he and his colleagues had to argue with the Company taking the line that a highly profitable time was in prospect, and they had to choose whether they would or would not preserve or make "this trade of Karnatt;" and, dealing with a suggestion that had apparently been made that they might have put up at San Thomé as San Thomé had desired, declared that if it had been so, "you must have sought out for such persons as were both stick-free and shot-free, and such as could disgest poison, for this is their daily practice at San Thomé and no justice."

Cogan went home through Bantam, and with the support of the council there, but had to stand an enquiry by the Company on the building of the fort and on other matters. Concerning the first it was held to be "a very indiscreet action when the Company's stock was so small, but if ever the Company have a plentiful stock it may be very commodious and advantageous for them." By September, 1644, the fort had cost £2,290, and would cost £2,000 more for its proper completion. Fifty men were its complement of soldiers costing £54 6s. 6d. per month and fifty more would be required, and then "we need not fear any inland enemy near unto us in these parts."

This in rough outline is how Fort St. George came to be built; it is said to have taken fourteen years for completion.

The Viziangar Prince had meanwhile confirmed the Nayak's grant, when or how, does not appear. The Dutch in 1644 were threatening to become all powerful, and the English feared the same low state for themselves as menaced the Portuguese and the Danes, but things took a turn; Sree Rangaroyalu, the last ruler of his house, welcomed the assistance of the English against the Dutch, accepted a visit from Mr. Greenhill and four other Englishmen, and in November, 1645, issued to "the Chief Captain of the English and the Company of that nation," much the same sort of grant as they already held. But he calls the fort Srirangarayapatam "my town," "the town which bears my name," "one of my new towns," and he freely gives to the Company the town called Madraspatam and all the ground belonging to it, and "all the government and justice of the said town shall be executed by you." By 1647, the King of Golconda's general, otherwise the Nawab, had pretty well made an end of the Vizianagar Kingdom, was in amity with the Madras authorities, and had confirmed all the English

privileges. And a famine in the place had killed 4,000 in five months, and left the settlement with one-third the former number of weavers, painters and washers, and with only three factors and thirty-three soldiers. More famines were ahead; the English did not beget them.

To this day people wonder at Day's selection. In the early part of next century Alexander Hamilton came there with much experience of Eastern seas. He considered it a most incommodious place, the surf greater than elsewhere on the coast, its foundation sand, no drinking water within a mile, the sun from April to September scorching hot, and the place habitable only by the sea breezes; the soil barren, the trade not satisfactory since the place produced very little of its own growth or manufacture and had to feed itself from elsewhere, being indeed an emporium like Holland. He had a biting pen, and had no great reason to love the Madras authorities; still he has to record that the place was populous and rich, because peaceful Indian traders were there not worried by "encumberers of trade"; and it was near the Golconda diamond mines, and good bargains were to be made. In 1639 one can picture the site of the fort as a spit of sand between the sea and the north branch of the Cooum river, with Madraspatam probably a small fishing village to north of it. The sand ridge would continue northward up the coast; on the landward side, back of the ridge, was a depression, in part a swamp running along what is to-day Popham's Broadway and ending in the Cooum; and beyond that the plain with its small native villages to be afterwards mentioned, at its highest not more than 24 feet above mean sea-level, but for the most part as low as from 2 to 6 feet. South-west lay the island, then much more of a marsh than it is now in heavy rain: it was regarded as a possible salt factory. Directly south of the river the country was open, known later by the name of the Choultry plain, with Mylapore and San Thomé on the sea face of it. There is some proof that Day did not settle without looking further down the coast, and his reasons—the goods he was in search of, an open roadstead, and a friendly native authority—are all on the surface, and were then sufficient for him as they would have been to any one with as small choice.

The name *Madraspatam* already existed; its etymology has been an enigma since. *Madrasa*, meaning a college, may be ruled out at once; *Madarasen*, the Christian fisherman, is equally impossible; *Mandarajya*, the country of the stupid, is good for a jibe but not otherwise. Mr. Leighton adheres to *Madeiras*—timber—though there is nothing to show any great probability of or propriety in such naming. *Madre de Dios* has been suggested. *Madirass*, "the Indian town with flat houses," is shown on the north of the fort in the print in Fryer's new account, dating back to 1673. In my early service I remember a European veteran making the word so distinctly of three syllables that I had difficulty in recognising it. The probability is that there was some connection between the place and Portuguese San Thomé, three miles off, which helped it to its name, or possibly the Dutch, 22 miles to the north, at Pulicat, had christened it. The similarity to Saderas, Sadras, Sadraspatam, is curious, but Dutch Sadras dates back only to 1647. The native name, *Chennapattanam*, after Chennappa, father of the Nayak, has lasted till now and will last.

Coming to the fort itself, the first full account we have of it is in Fryer's book. It is there depicted as an oblong quadrilateral, walled on the north, east, and south, open on the west to the river, save for the garden and house walls, moated also on the south, and protected at each of the four corners, at the water-gate on the east and the two gates on the north, by 10 or 12 guns. Palisades connect the corners with the sea on the sea face. Inside this outer fort is the original fort, 108 by 100 yards, similarly protected at each corner by ten guns, with culverin along the battlements, and the governor's house set down diagonally in the middle. Two hundred men, he says, are mounted for duty daily, and there are 700 English and Portuguese in the Company's pay. I may as well observe that the doctor's figures are not always accurate, but that at this time Madras had good reason to have a small army. He has a good word for the houses and streets. The inner fort stood more or less on the site of the present secretariat. The English folk—Company's servants and freemen—occupied the south and west, the Portuguese the north of the outer fort, with a chapel named St. Andrew's for their use: you may note it in Fryer's print; elsewhere I find the date 1675 assigned to it. The whole enclosure went by the name of the White Town. Outside, to the north, divided by a wide parade used as a market place, was the heathen town Maderas, of "divers long streets, chequered by as many transverse." This was the Black Town of those days occupying what is now the

north glacis and beyond, peopled by the natives attracted by the Company's trading.

In 1670, Governor Langhorne obtained from the Nawab of Golconda a re-grant of the fort and town for a payment of 1,200 pagodas per annum, free of any further liability, and this was confirmed by the succeeding Nawab in 1672. By 1677, the forthouse and outer fort walls required restoration; St. Mary's, the fort church, was built at the expense of the residents in 1678-80, the first church of the English nation in India, and retaining to this day most of its original construction; in 1688, the White Town was 400 yards long by 100 yards broad, and had 12 streets with 129 dwelling - houses and godowns, yielding a yearly rent of 124 pagodas 9 fanams. A directory exists for that period, showing owner, occupier, and rent due, and there were 11 christenings, 13 marriages, and 101 burials in the year. Job Charnock came there with his people in 1689, and left the next year to found the capital by the Hugli. In 1692, by petition made to the Vizier of the Mogul, then at Gingee, that the Mogul himself should grant a *firman*, that the rent of 1,200 pagodas for Madras and Triplicane should be taken off, that Tandore (Tondiarpett), Purasapakam, and Egmore, three small towns near by and worth 300 pagodas per annum, should be given rent-free, and that they might coin rupees with the King's stamp, grant, it is said, was made accordingly, but I cannot find that the rent ceased to be paid. The grant cost 1,500 rupees, as present to the Nawab Zulfikár Khan. In 1708, on a present of 200 pagodas, the Nawab granted Trivatore, Kattiwak (Ennore), Nungambakam and Viyasarpadi; it cost 200 pagodas more to stop the clamour of the officials at San Thomé, who held that the towns valued at 1,500 pagodas were worth 3,000, and even the *firman* of Farokhsir did not put the Company in possession without much trouble. The tale of acquisition may as well be completed at this point. Vepery, Perambore, and Pudupakam were obtained in 1742, on the accession of the young Nawab Saadutullah Khan, and Mylapore and San Thomé in 1749 from the Nawab Mahomed Ali in gratitude for English assistance. Trivetore and Ennore are outside; the others make up the present municipal area.

The local revenues of the Company about 1732 were from farms of betel and tobacco, spirit licences, measuring duty on grain, rents of the out-villages, quit rents of the town proper, scavengers' duty and minor items, but mainly from sea and land customs, yielding a total of over 70,000 pagodas—about £28,000—and the local charges ran to about half this sum.

Recurring to the White and Black Towns: in 1689 in fear of a Mogul force Black Town was ordered to be entrenched and walled with turf and clay, and by 1692 a brick wall took its place, in respect of which ex-Governor Yale next year was invited to pay up 3,483 pagodas and refused to do so. This wall had defences, "points" they were called, similar to those of White Town. Lockyer found it so in 1703, and White Town much as already described. A new fort house was built sometime in the early years of the century, and the inner fort walls replaced by the fort square in 1715. By 1733 the White Town is 620 yards long on the surface, 320 yards on the north and 180 on the south face, the river continuing to limit it on the west as before at more or less the north-south central line of the present fort. Commodore Barnet in command of the British squadron in the war that broke out in 1744, who died at Fort St. David in 1746, wrote of it scathingly, "works rather built by chance than by design . . . . bastions placed contrary to all rule; the curtain no better than a long unflanked garden wall." Peyton and the fleet having vanished and left the seaway open, the fort stood only a three days' bombardment by La Bourdonnais, and surrendered at discretion.

Before that time Black Town was stretching out arms northward—Muttialpett, east of what is now Popham's Broadway, and Peddanaikpett, beyond the channel that came down the Broadway. These pettahs had "out choultries," or batteries for defence, in a line westward from the present north groyne of the harbour to the north river, and adown it to the Cooum, but when serious trouble arose the smallness of the military force of the Company, and the necessity of concentration on the fort itself, made them useless for their primary purpose.

Let us now endeavour to realise in some measure the life and work of the settlement not embodied in wall and battlement or in adding village to village during these hundred years. There were twenty-one agents, presidents, or governors, from Aaron Baker to Nicholas Morse; many notable, several masterful, not all honourable, perhaps, as we count honour at the present day, but, to judge by the records, zealous to act the part of "a good husband for the Company, never giving a present but when absolutely necessary and

with a prospect of getting some privilege for it." Giving, however, begat giving, and too often the privilege obtained was to be let alone. Another note could be sounded as in 1687, when the Council is instructed, probably by Josiah Child, Chairman of the Court of Directors, that the King of Golconda is to be told that "We are none of his subjects and claim the sovereignty of the small territory belonging to Madras paying unto him our agreed tribute of 1,200 pagodas per annum. And if he break with you upon these terms we require you to defend yourselves by arms, and from that time renounce paying him any more tribute." These were brave words if the writer had been in Madras instead of in Leadenhall-street.

The Company was not easy to serve, in the early days at least; it was an offence to them that their servants who could not possibly live on their salaries should make money in private trade; they were only too ready to give ear to accusations and back-biting and to strike without hearing. Their wrath against interlopers was justifiable and understandable enough; such were pirates or poachers in the Company's preserves. They were pious in their despatches, zealous to promote religion according to the tenets of the Church of England, and tolerant in a measure of Romish practices and priests for those of that faith provided that they did not proselytise. The local officers were tolerant in greater measure—of necessity—but in religious supply they admitted no authority, Padroado, patriarch, or other, to claim rights of appointment to minister to the Catholic community within their bounds.

And it is difficult for us to comprehend how a scrupulous servant, governor or other, could discriminate between his own and the Company's trading interests. Possibly there was an idea that whatever was not occupied by the Company's funds or orders was the natural right of any servant that had money for employment, and that the company suffered no injury thereby. When Governor Yale fell out with his Council he swore he had not used the Company's cash to his own profit but had often freely supplied their occasions, and for two years past had nearly 100,000 pagodas of his friends' consignments lying dead for want of an opportunity to invest it, besides some of his own. On the Council's insinuation that his estate might on inquiry be found "too mean" he was hurt, and became ironical: "I think you are a little unreasonable; that my 20 years' diligent service in India and trading above 500,000 pagodas should be too poor a crop for you is hard, but I cannot help it, having used all honest endeavours to do better, so pray be contented."

Wheeler notes of Governor Higginson (1692-98) that he seems to have been the first Governor of Madras on record that retired from the Residency without a stain on his name. We should not grudge one white crow to a rookery—if it is at all proper to so describe honourable gentlemen—but he had a warm patron in Child, and I have not found the record of his acquisitions.

Pitt's "great concerne," and the trouble it was to him, are graphically set forth by Sir Charles Lawson; the spirit of the interloper had dwelt too long with Pitt for eradication, and he could not have denied himself the luxury of a good private bargain. When the Company did grant liberty to their servants to trade in the East and to send home goods under declaration, cloths, pepper, and precious stones were specifically *tabu*.

The Fort was a working and living residence with the Governor as head of the business, responsible with his council to their honourable masters for maintaining and extending trade, showing profits, and keeping the establishment in order to these ends. Apprentices, writers, factors, junior and senior merchants, councillors, surgeon, chaplain, and schoolmaster, lived under the President's eye, and were in commensality till 1722. Table expenses had then become excessive and a fixed sum had to be prescribed. The councillors divided oversight duties among them as book-keeper, warehouse-keeper, customer and justice, mint master, paymaster; elaborate rules, business, moral, and disciplinary, for the conduct of all from councillor to garrison soldier, were promulgated in Langhorne's and Master's times, with penalties of purse and person that, especially for the soldiery, were not trivial. The ultimate cure for the obdurate was to be sent home. Drink and the absence of healthy recreation clearly had much to answer for in misconduct.

The settlement of those that were useful for manufacture and trade in the Black Town and in the Pettahs was encouraged. Triplicane was a weaving and painting suburb in the early days. Governor Collett, in 1719, fostered the establishment of a hamlet called after him near to Trivetore; Chintadripett was built on advances in 1734, also for the promotion of the weaving trade. Contracts had to be arranged

with the native suppliers, dubashes, or workmen; books and accounts kept; bleaching, dyeing, painting, weighing and valuing of precious stones and metals, examining, passing, and packing for shipment seen to; the English stocks of broadcloth, iron, lead, tin, copper, weapons of offence, the lustres and mirrors the remains of which are so prominent in native furnishing till this day, all to be set out and sold. Article 9 of the Company's charter of 1693 bound them to export annually English goods to the value of £100,000 at least. The principal exports to Europe were cotton goods of course, with pepper, cardamoms, rice, sandal-wood and precious stones, and tea, china, spices, and other things obtained from the Far East. The Company's trade was small compared with that of its servants, the free merchants or licensed traders, Armenians, Jews, and others. The first market place I said was between the Black and the White Towns; later the sea gate was the mart; Hamilton found the council chamber or the governor's apartment in use; at the end of the century the Exchange was built. The native workmen would strike occasionally and withdraw and have to be cajoled, paid, or coerced to return; attempts to tax them for municipal improvements were always resented; and the quarrels of the right and left hand castes—the Telugu Comattis and the Tamil Chetties—were a feature of the native town life for long requiring the Council's interposition. On this side of the world calicoes and fine muslins were in great demand, and the home clothing industry invaded. In 1719 the Spitalfields weavers broke out and apparently behaved much as the Swadeshi rank and file in Eastern Bengal have done or are reported to have done in recent times. In 1727 the Council got alarmed at the diminished trade and apprehended utter ruin, ascribing this to the French, Armenians, and Moors (Mussulmans) using shipping not of the port and importing elsewhere, to English supercargoes taking up Madras money for trading and dallying in Bengal impeding "quick circulation," and to unlicensed persons trading; and took steps accordingly. The Council might fittingly regulate their own servants, reason with Armenians living under their protection, and deport interlopers; but when, as in Governor Macrae's time they took to fixing the price of grain under the market rate, forcing sales, and forbidding the export of silver and gold, circumstances as well as the Company were not long in showing the absurdity of their action. The Dubashes, or confidential servants of governors and others, had a faculty of bringing disgrace to their masters, which says little for the control their masters exercised; the popular suspicion—perhaps envy—of the class has had a long life.

In dealing with the native authorities the Council's policy was peace and conciliation, involving fair words and presents till one wonders how their exchequer stood the drain thereof. Child, as has been shown, was ready to fight, and when Daud Khan in 1701 refused their presents as insufficient, and began to blockade Madras, the determination of the later Pitts showed itself in their ancestor, and "considering that if there be not an end put to those unreasonable demands of Nabobs, the ill consequences will in a little time be no less than a vast annual charge to this place, and we all concluding this to be a proper time to withstand them," he beat the martial drum accordingly. Daud Khan's fondness for strong waters did no small service to the Company's affairs at this juncture. The next year he was more truculent, and it cost the Council 20,000 rupees to get rid of him. A more amusing episode was when John Pitt, cousin of Governor Pitt, being sent out under the charter granted to the new company, with the title of Consul, anchored in Madras Roads in 1699, on his way to Masulipatam, and intimated his arrival to "the President of the Company, yet by permission on the coast of Coromandel," and that he would salute if he were saluted. The Governor found the communication as well as the superscription "very odd," suggested that his cousin should read the Act of Parliament whereunder the old Company existed till 1701; didn't know if the *soi-disant* consul was a consul or not, but instructed him that it fell to him to salute the flag ashore and according to custom and good manners that would have been acknowledged; which made John Pitt so angry that he forgot his manners altogether and promised revenge for the "scurrilous letter" from Masulipatam. The old and the new companies amalgamated in 1701 and got their charter in 1702, and a son of Consul Pitt ruled in Madras from 1730 to 1735. One item of the new charter in which probably Streynsham Master's hand is traceable, is a contemplation of license to the Company's servants to trade in the Company's ships.

Reverting now to the capture of Madras in 1746, Dupleix and La Bourdonnais disagreed

for weeks over the treatment the place should receive, the former desirous to sweep the English from the country, the latter ready to hold the place to ransom; meanwhile the plunder of the city was making its way to Pondicherry. A cyclone sent La Bourdonnais packing; the Nawab's son and Dupleix fell to fighting to the confusion of the former, and Governor Morse and others were marched off to Pondicherry. Robert Clive, writer, took French leave, and reported himself at Fort St. David, which became the British headquarters. The French held Fort St. George till the peace of Aix-la-Chapelle had effect in 1749; they cleared away the Black Town, and made a glacis north and south of the fort. In 1743 Major Knipe had reported to the Council on suggested improvements, and had accepted the proposal to turn the river away from and enlarge the fort on the west side which had always been insufficiently protected. Government was reseated at Madras in 1752, but from 1750 Knipe's plans had attention from the engineer-general, Benjamin Robins, and when Robins died his designs were carried out. Work began in 1755 and continued for three years with 4,000 labourers constantly employed, Governor Pigot actively superintending. The result was the fort somewhat as we now have it in shape. The extension doubled the internal area. The work done was only in time, for in 1758 the place was invested by Lally, Stringer Lawrence retreating into it before him. Lally shot and shelled it from the north and west and endeavoured to sap it for two months; the strenuous and gallant defence and his army's exhaustion compelled him to raise the siege. Simultaneously the English fleet under Pocock appeared in the roads, but the conflict was already ended.

Much naturally had to be done for renovation, and the Court decided to make it an up-to-date fortress. Work went on from 1760 till 1780. The curious will learn what was done from Colonel Love's book. The interior is 620 yards north to south and 330 east to west; and the enclosure is 42 acres; the total to the foot of the glacis 102 acres; the full armament was 534 guns. Its present armament and the disposition thereof are not to be talked of: there are more modern defences now in the shape of three batteries along the sea shore. The buildings within the extension date, of course, from that time; new barracks have been built by the St. George's Gate; the north wall and gates, the church and some of the houses south of it are the oldest buildings now. Clive was put up in the latter quarter on his arrival in 1744.

According to Mr. Twining, in 1793 the European merchants' counting-houses, stores and warehouses were still in the fort; so also were the best shops. Cornwallis entered it by the sea gate in 1792, and Colonel Arthur Wellesley is said to have occupied a house opposite the San Thomé gate in 1798. The fort house enclosed by the fort square continued to be the Governor's official residence even after the present Triplicane garden house was acquired. The present Accountant-General's office in Charles-street—the old Admiralty House—was also occasionally used by the Governor for public purposes.

The fort house underwent large repairs in 1819; wings were added to it, the fort square cleared away, the old banqueting hall between it and the sea gate, with its pillars that performed a journey to Pondicherry after 1746, did duty there and returned after the day of vengeance in 1761, became a clerks' office and eventually the record room. The fort house is now the Government Secretariat tenanted by secretaries and clerks who sigh for roomier accommodation; the headquarters of the Madras Military District are in Hanover-square. Changes in military administration are rapid at the present day, but I believe the Sepoys from Perambore still mount guard at the gates, and the European force is the wing of a regiment and a company of garrison artillery. The gun proclaims noonday to the town and shipping, the Executive Council meets once a week, and the Legislative Council, when summoned, in the Council chamber on the top floor overlooking the sea and St. Mary's. Commerce is fled to Black Town many a day since. But I do not think the fort sits sorrowful, though it may please the pride of youth to call it "an anachronism," "a withered beldame," or any the like scornful name, and to forget to honour father and mother to British India on the east, and on the west also if you admit that Clive's destruction of the pirates at Gheriah lifted Bombay from its low estate, for Madras may assuredly claim Clive as among the greatest of her makers.

> "Clive kissed me on the mouth and eyes and brow,
> Wonderful kisses, so that I became
> Crowned above queens."

May I vary the continuation to a placid mother now playing her children's games?

While the fort was receiving attention it was also considered proper to protect the Black

Town of the newer day—the old pettahs—along the lines of the old out choultries and the bound hedge, conjoining them by a strong wall. It was guarded by flanking works at intervals, and the ground outside cleared for a width of 600 yards. The length of the wall was about 6,000 yards. The notorious Paul Benfield had a deal to do with the expenditure for general defence; 20,000,000 pagodas — 8,000,000 pounds sterling—are said to have passed through his hands in five years. The wall continued as a whole till 1859; some of it still exists; part of the western esplanade became the People's Park, and the northern served the Madras Railway Company's original line into Royapuram.

In the middle of the eighteenth century the English and the French began to play for chief place in India with native princes for pawns; Stringer Lawrence, and Clive his pupil, had occupation, and the Madras Sepoys and the European regiment, which developed into the Madras Fusiliers, came into existence. Governor Pigot, in 1756, sent Clive, then Deputy-Governor of Fort St. David, along with Eyre Coote to Calcutta to avenge the capture of that place and the Black Hole outrage. That ended in the victory of Plassey, duly commemorated by Clive's son on the southern pediment of the banqueting hall in Triplicane. Active hostilities with the French were resumed in 1757; the defence of Madras in 1758 stemmed the tide which had overturned Cuddalore and Fort St. David. The French were vanquished in all quarters, and finally Coote captured Pondicherry and razed it to the ground. Mohamed Ali, Nawab of the Carnatic and our particular bantling, looked to rule by our assistance; the Company required money to pay the heavy war expenses and to prosecute their trade; the Nawab was ready to pay if only his subjects would pay him.

Unfortunately war does not immediately produce the fruits of the earth but destroys them, and exaction was no easy matter. Tanjore was a valuable principality affecting independence; its Raja was squeezed, and Pigot in 1763 prevailed on the Nawab to cede the Chingleput Jaghire or district. The treaty of Paris in that year restored the *status quo* with the French, and recognised the Nawab as independent and an ally of England. The Nawab without ready cash promised what he could not pay and fulfilled his wants by borrowing. Too many were ready to lend. By 1767 his debts were 88 lacs of rupees; this was consolidated into a 10 per cent. loan with—if you please—three Members of Council for trustees, and fifteen districts assigned as security for repayment. Commissioners were sent out in 1769 and 1771 to support the Nawab's independence under the treaty. Their presence was not a pleasure to the Company's servants, especially when the envoys agreed with the Nawab in preferring alliance with the Mahrattas to alliance with Hyder Ali, both of whom were now giving trouble. Hyder had dictated peace to the English at St. Thomas's Mount in 1769, a main article of which was a mutual alliance in defensive wars. The English failed him presently in assistance against the Mahrattas and he never forgave them.

In that same year Warren Hastings appeared in Madras as second in council, charged with the suppression of malpractices over the Company's piece goods and proud of his success in that regard when he departed in 1772.

The Company's trade was dwindling away. The country trade could not live under warfare, the China trade passed largely to Calcutta and Bombay. But the Company's servants in Madras throve—what with contracts for public works, army and naval supplies, and leases or farms in the districts that came under administration. In the sixties, seventies, and early eighties Mr. Leighton says Tammany ruled Madras. Trouble arose with Tanjore, which ended in its being reduced in 1773 and its revenues becoming available for the Nawab or rather for his creditors. The directors, however, by a majority determined to restore it and put an end to the misconduct of their servants. Lord Pigot, as he had then become, was sent out, but was kidnapped by members of his council interested to retain Tanjore, and died in restraint. The directors then sent out Sir Thomas Rumbold, who did well unto himself if to no one else, if he is truly credited with making £600,000 in the two years he was in power. Directly after he went Hyder burst upon the Carnatic. Baillie's disaster cowed General Hector Munro and all, and Warren Hastings sent Coote to succour them. Five regiments of Bengal Sepoys marched down the coast and through Madras to the Mount, and the second battle of Pollilore, and that at Porto Novo recovered British prestige. Lord Macartney took over charge of the Government in 1781, and the country had need of such a man. He was offered £30,000 as a present by the Nawab on his first visit, and to

the Nawab's astonishment, declined it. His troubles were over the Treasury's emptiness, the insubordination of the military officers, and the lack of men of high character and good attainments in the company's service. On retiring he declared his savings with reference to Pitt's act or for his own reputation as £30,000. Hyder died in 1782 and Coote died in Madras directly after he had come there in 1783 in expectation of Tippu's troublesomeness. In Sir Archibald Campbell's time, 1786-89, the Board of Revenue was started to deal with the land assignments made by the Nawab to pay the military forces and his creditors; also the Madras Post-office; and to the Governor and Lady Campbell were due the military orphans' asylums affording great succour to a large class sadly in need of it. Dr. Andrew Bell was an efficient superintendent for some years. Ootacamund has now received both sexes; and the civil orphans, poor whites and Eurasians, whose case was taken in hand 100 years ago, are now lodged in the buildings the military orphans occupied in Poonamallee road. When General Medows was Governor, Cornwallis thought it well to come and take charge of the operations against Tippu. Peace was arrived at in 1792, much to Tippu's impairment and to the delight of Madras which commissioned the Governor-General's picture and statue; the former is now in the Banqueting-hall, the latter—by Banks—was set up in the fort square about 1800, moved to the front of the Government office in 1825, and from there, on account of the havoc the sea air was causing to the marble, has just been transferred to the Connemara Library. It may be added here that Cornwallis re-visited Madras on his way to his second charge in 1805, and was presented with an address; and on his death the Cenotaph at Teynampett was instituted. The Madras folk could recognise and appreciate public devotion and righteousness whether they practised these virtues or not. The French Republic having declared war in 1793 the French possessions were again captured, and in Lord Hobart's time expeditions were sent from Fort St. George and took the Dutch territories—the Dutch having had to stand in with France—in Ceylon, Malacca, and the Spice Islands, so greedily longed for 200 years earlier. Tippu saw his opportunity while Bonaparte was pursuing his career of conquest in Europe and giving England enough to attend to in that quarter. Colonel Wellesley came from Penang in 1798, made himself acquainted by travel with the interior, and thereby no doubt was the better able to assist Lord Mornington when he, spurning the local deprecation of war, descended on Madras for the last fight with the Sultan. Lord Clive's five years' term was one of conquest and large territorial extension, and of the establishment of courts of justice. The Governor-General, besides settling the partition treaty, arranged the affairs of Tanjore and of the Carnatic, virtually annexing these territories. The portrait of him in the Banqueting Hall obtained by public subscription represents him seated in the verandah of the fort house, St. Mary's Church on his left, and the Union flying over the Sultan's standard.

Mr. Leighton gives an interesting description of the manners and customs of the Europeans of Madras at the end of the century. There was abundant hospitality, much and excellent drink, especially Madeira, even pale ale and porter; and the gentlemen drank heavily; the hookah after dinner was in sonorous evidence; Trichinopoly and other cheroots are of a later time. Deschamps had not then arisen, furniture and carriages were imported. Household goods and millinery were brought out by the East Indiamen; then, as now, the ladies would import for themselves from Paris and London; headgear and hooped petticoats were things to marvel at. A young lady, newly arrived, had to stay at home with an attendant squire till all had called, instead of as now setting off with her chaperone to drive over Madras to be introduced; and it must have been a trial to find herself restricted to one partner at a dance and to receive his call next day, unless, indeed, he were to be particularly desired or eligible. The chaperones played cards and took snuff Society was musical, or had the instruments for being so. With the men, duelling, gambling for high stakes, and wagering were common, Fashions in dress, manners, and morals took colour no doubt from this side of the world. The Pantheon, now swallowed up in the Central Museum, was a place for balls, banquets, and theatricals; later on the old college was used for the latter. At the Pantheon Sir Arthur Wellesley was entertained in 1805 on his way home after Assaye, when India had no more to offer his ambition, and opened the ball with Lady William Bentinck. He was invited to sit for his portrait, which was obtained in 1808. But Madras had small reputation for piety as concerned those who

had most to be thankful for, religion dwelling with the missionaries and the Vepery people. James Cordiner who succeeded Andrew Bell at the asylums at the end of the century found the civil servants superciliously arrogant, looking down on the military "to which they owed their pomp and splendour"; the private merchants more modest but independent; the lawyers pleasant and amassing money; all classes of Europeans living sumptuously and many spending £2,000 to £10,000 annually in maintaining their households. The men of a hundred years later might well sigh for such possibilities of saving.

The Houses of Agency, the collapse of one of which, or a lineal descendant thereof, has just brought so much heartrending sorrow on the thrifty of the whole Presidency, came into being through Pitt's Act restricting the earnings of the Company's servants, setting them to work with their creatures as *benamidars* to circumvent the law. Advances to the Nawab on mortgages of the revenues of the districts and controlling through their own managers, forestalling crops and forcing up prices continued the old game of hasting to be rich by grinding the faces of the poor, the while spinning inventions in this country with heavy import duties ruined the Indian production of cloths. When in 1803 a Commission sat for the final settlement of the creditors of the Nawab, it allowed £2,686,148 out of claims for £30,404,519, and declared that the investigation had deprived no one of any just right, while as to some of the cases reported it had defeated the most iniquitous combinations of fraud which were ever submitted to a legal tribunal. Under Cornwallis's arrangements for the service, the former evil things had room to pass away. They were not special in India to Madras, they are not special to any time; where there is no sufficient restraint of the law, of religion, and of morality, power will be abused by the unworthy and the public exploited.

The tale of the nineteeth century, if there were time to rehearse it, would be one of orderly and gradual improvement under settled and civilised Government. The Madras Government Bank was established in 1806, and lodged under the Exchange in the fort; the Bank of Madras that now is opened in 1843. The new Observatory was built in 1818; the Madras Literary Society dates back to the same year. The beginning of the trunk roads was in 1822, in Sir Thomas Munro's time; the Madras Club was founded in 1832; the Medical School in 1835, and a Chamber of Commerce in 1836. The Christian College of the present day, that has so much to do with education under its veteran principal Dr. Miller, had its beginning in 1837. A Madras "University" was opened in the College Hall in 1841; the University as an examining Corporation was created in 1857. In 1842 the first Peninsular and Oriental steamer called; the esplanade lighthouse, was built in 1844, previous lights having been in the fort. The first telegraph line was from Madras to Poonamallee in 1854. The Mutiny led to the raising of the Volunteer Guards. The pier for landing and shipping, not through the surf, was built 1859-61. The Duke of Edinburgh visited the place in 1870, the King (as Prince) in 1875 laid the stone to commemorate the harbour works, then about to be commenced; the Duke of Clarence's visit was in 1889. There was through railway communication to Bombay in 1871, to the south-west coast in 1861, and to Calcutta in 1901: the South Indian Railway ran through south to Tuticorin in 1879. The beach batteries were built in the same year. An era of public buildings coincides with Sir Mountstuart Grant Duff's administration, 1881-86—the Victoria-hall, the post and telegraph offices, the Gosha and Ophthalmic hospitals, and the Marina. The new Law Courts were completed in 1892; the lighthouse atop is 166 feet above sea-level, and the light is visible at 20 miles. In Sir Arthur Havelock's time the Moore Market was opened and large improvements made to Government House. The chief public works of the near future will be a Government office, collecting as many public officers under one roof as the want of a thoroughly satisfactory site will permit, and a Presidency jail. There has been a deal of private building of late years in the way of new shop premises along Mount Road, and small dwelling-houses are breaking up the old spacious compounds of Egmore and Nungumbankum.

As affording individual opinions, in 1810 we have Mrs. Graham writing enthusiastically:—"The town and fort are like a vision of enchantment. The public offices and store-houses are fine buildings. The English at Madras have a great deal more of external elegance than at Bombay, but the same influences operating in the Society I find it neither better nor worse." And she refers to the army and civilian jealousies. It was the fashion for ladies and gentlemen to repair in their gayest equipages to Mount-

road, and after driving furiously along it to loiter round and round the Cenotaph for an hour, "partly for exercise, partly for the opportunity of flirting and displaying their fine clothes." Visiting went on from 9 a.m., and till tiffin was over. Mr. James Wathen about the same year visited Madras from July to September—far from the best time of the year—and is charmed with everything from the appearance of his lovely country women in the dance to the dignified conduct of the Governor. At the service in the fort church he found the ladies occupied the nave; the Company's naval officers were in one aisle and the military officers in the other, all in full uniform; and in spite of the punkahs the heat made his situation "almost intolerable." He parted from the place in acute melancholy, for he had never been so kindly entertained, and that by Hindus, Mussulmans, Persians, and in particular by his own countrymen.

The assembly at the Cenotaph—at the fourth milestone of the Mount-road—persisted for long. A later picture than the above is of five o'clock of an April afternoon, a troop of civil servants riding, puffing, panting, perspiring, habited in broad cloth great coats closely buttoned and wearing top-boots, going to dinner in a tent near the long tank. A Judge is driving a spirited horse seated in a lofty car "like a demigod," dressed in a first-class box-cloth coat, cape and all. In the town the narrator sees a dashing pair of horses, dragging a lofty curricle bearing the Postmaster-General, again in a great coat coming down to the heels, but thrown aside over the right knee to show a new pair of top-boots; the lady in warm looking pelisse with the addition of a fur tippet, her hands and arms buried in a brown coloured hair muff. It is a great thing to be in the fashion; in my later time I have known men who wore heavy European garb, because, they said, it was coolest, but most of us nowadays find the lightest clothes a burden in April.

The letters of a lady about 1837 describe dinner-parties as rather dull, grand, and silent, all tired with the heat and work—this in January; the houses greatly infested with mosquitoes; people talk a little to those next them in a very low voice, but one scarcely ever hears any topic of general interest save steam navigation and the changes in the service. After dinner the company sit round in the great gallery-like rooms, and talk in whispers; sometimes there is a little music as languid as everything else. "The ladies are all young and wizen, the gentlemen all old and wizen. Every creature seems eaten up with laziness." She is young and full of life and curiosity; goes to a native entertainment and describes it; the house got up as a French lodging-house—dancing girls, conjurers, and a great supper. As to the appearance of the place, she says it is flat plains of sandy ground, covered with a little harsh dry grass, half-cultivated gardens with high hedges, and large dilapidated houses. In general there is very little beauty, either of architecture or scenery. However, she says, Madras is not considered a good specimen. Madras, certainly, is not at its best in February, especially after a short monsoon; dinner parties are anything but stiff or dull now; the topics of conversation are not limited, the company no doubt being more diversified than in her day; and the mosquitoes can be kept under by kerosene on their breeding places. Gardening is a favourite occupation with many; every house has its surroundings of croton and other foliage plants and shrubs. Roseries and ferneries are common. Some are able to put down attractive lawns; and in the cool weather with care and attention flowers are in profusion. The water supply and the easy procurement of seeds and plants have, of course, made all this a much easier matter than it once was.

I have said little of the native population for the best of reasons. One may go to a wedding, to an entertainment of a Governor or Viceroy, and meet native gentlemen in public or social work or in full friendly intercourse. All this does not justify pronounced opinions on social questions or matters among them. Manners and many things else have altered much in even my 35 years; the old men of my young time could be friendly and reserved at once, and clothed themselves in the flowing garments of their country looms, with their feet in sandals if in anything. Now, manners and opinions are free; the cloth coat, probably trousers and patent leather shoes are the integuments of most that can afford them for full dress purposes. The flannel jacket is not despised either. They are building and furnishing houses on European lines; the long armchair is everywhere; indeed, a *rapprochement* in idea and in action as in the English tongue is progressing rapidly. A Cosmopolitan Club exists in Mount Road; societies of all sorts for political, religious, charitable, social, moral, mental, and physical ends are numberless—I note even a Sir Henry Irving

Association. With so much mental activity called into being by education, the objects and uses of these associations will increase and extend more and more. I see an improving standard of action in public life in inreasing volume, and there is in Madras but little of the professional unworthy agitator—a contrast with some places greatly to the credit of Madras.

The Black Town is now George Town in commemoration of the Prince's visit in 1906, and in deference to native sentiment. It is about two square miles in area, ill-built, densly populated, poorly drained, the chief business part of the city; and it contains the High and other Courts and the Law College, the mercantile offices, the Madras and other banks, the Post and Telegraph office, the Custom House and Collectors' offices fronting the harbour; the old Mint, now the Government Press, and other Government offices, with various uses; the Madras Railway Central Station, the General Hospital (among the best in India), and the Medical College; the Memorial Hall, founded in 1861, in thankfulness for escape from the Mutiny, Pacchiappa's hall and Educational buildings, the Christian College, with its hostels, the Municipal office; St. Mary's Roman Catholic Cathedral, the Portuguese and Armenian churches, all of considerable antiquity, and other churches and chapels. There is no lack of places of worship throughout Madras. The fort and its glacis are outside municipal jurisdiction, and the Military Department have powers over a certain range surrounding the fort.

Proceeding with a rapid survey of the city by blocks, we have on the north Tondiarpett, the Tandore of the old times, between the sea and the Buckingham Canal. The East Coast Railway runs on its south and west. It contains cotton mills, the Leper Hospital, the Monegar Choultry for the native poor and incapable, dating back to 1782, various churches and mission houses, the Emigration Depot and the Robinson park. Washermanpettah, one of its villages, carries us back to the time when the Company's bleachers found it advisable to move there from the fort neighbourhood on account of the better quality of its water. To the south-west lies Perambore, bisected by the South-West Railway, with Viyasarpadi on the North Trunk-road; the Buckingham and Carnatic spinning and weaving mills, the Madras Arsenal workshops, and the salt stores of Government, supplied by the Ennore group of factories and in connection with the railway, are on the south and east.

Southward of Perambore and north of the winding Cooum, are Vepery, Purusapakam and Egmore. On the east of the block is the People's Park, due to Sir Charles Trevelyan, and 116 acres in extent, having, on the south of it, the Moore General Market, which cost about three lakhs, and the Victoria Hall, the idea of which originated with Sir Arundel Arundel, and released from debt the other day by the Raja of Vizianagram; in the middle of it is a small zoological garden. The Penitentiary—the Madras jail—is across the road on the Cooum banks, not unhealthy in spite of its too frequently odoriferous neighbour. Then come the Gun Carriage Factory, the Electric Tramway offices and power station, the Doveton College and Girls' School intended chiefly for the Anglo-Indian community, an animal infirmary, the Government Veterinary School, the S.P.C.K. Mission Press, St. Matthias and other churches. Vepery is pre-eminently the Eurasian quarter. On the extreme west in Kilpank is the lunatic asylum, in the south-west the orphan asylums. Crossing the Poonamallee-road, traversed in 1751 by Clive with his small band of 500 and a few guns to take and hold Arcot, there is the Friend-in-Need Society's premises for the European and Eurasian poor and infirm, started in 1807; the School of Arts which, with little success, has endeavoured for fifty years to imbue the country with English ideas of art, and will find any *métier* it has in teaching industrial arts and crafts; St. Andrew's, or the Kirk, built by de Haviland 1818-21, its steeple, 165 feet high, a fine piece of architecture, but defective acoustically; the Government Maternity Hospital dating back to 1844, and the Ophthalmic Hospital to 1867, both excellently housed and doing splendid work; and the Government Museum, Connemara Library, and Victoria Memorial-hall—the first established in 1851 and intended to illustrate the natural history, natural resources and manufactures of Southern India, and the manners, customs and antiquities of its inhabitants, with a most interesting coin and arms collection, and remains of Buddhist sculpture from Amararati; the second with a growing library and excellently furnished, both under the gifted and genial Mr. Thurston as superintendent and curator. The Victoria Technical Insti-

tute is materialising at present in the Memorial-hall, the foundation-stone of which was laid by the Prince last year. It is proposed to use it for a permanent exhibition of the best specimens of the arts and crafts of South India, for sale and for exemplars; the theatre or lecture-room in the Connemara Buildings has not yet found its intended use, but may when the scheme of technical instruction is settled and at work. The South Indian Railway traverses Egmore east and west along the banks of the Cooum and the fort glacis up to the beach station at the harbour, being there linked up with the Madras Railway. A new station is in hand at Egmore.

Nungumbankum, described in 1708 as under Egmore, is mostly remarkable as containing the Observatory and many of the fine old garden houses. The Observatory dates back to 1792, and is due to William Petrie, Sir Charles Oakeley, and the Company. It is chiefly occupied now with meteorological work and keeping the time for India, the Observatory for Solar Physics having been transferred to Kodikanal, on the Pulney Hills. The office of the Director of Public Instruction—formerly the old college—is near it on the Cooum bank, and the Madras Literary Society owning some 45,000 volumes has recently been provided with a new building adjacent. In the south-east on Mount-road is the Elphinstone Hotel, once the Amir Bagh, and later the "Choultry Plain" from which the Commander-in-Chief used to issue his orders.

Next may be taken the division east of Egmore and Nungumbaukum, south of the North Cooum and the fort, and north of Peter's and the Ice House Roads, being the Island, Chintadripett, Triplicane, and Chepak. The bodyguard lines, camp equipage depôt, and the English, Scotch, and Roman Catholic burial grounds, occupy the west side of the island; the rest is given up to parades and to sport, the Gymkhana Club for racing, polo, football, and golf, having a pavilion there. Munro's equestrian statue by Chantrey stands in the centre. South of the fort is or rather was Cupid's Bow, the meeting place of rank and fashion when I first saw Madras; I remember my companion being invited by the Governor's A.D.C. to understand that a bowler hat or its equivalent was not in order there in the evening. Chintadripett was founded for weavers in 1734; I heard Lord Napier say it was simply St. Andrew's pett; if so, the Kirk is not responsible. The park named after that Governor, 24 acres in extent, is a great boon to a squalid quarter.

In Triplicane, Government-house requires more than a passing word. The garden-house—by which may be understood a good roomy habitation with a considerable area around it—is a distinctive feature of European Madras, and I do not hesitate to say has increased the average of European life there. The dweller in Calcutta cannot profit by looking from his office or bedroom window on his cook or horsekeeper at their daily avocation, although his proximity may stir them to industry. Some garden houses boast a golf course in their own grounds, the generality of them have a few acres. What was probably the first—the Company's Garden-house—was built in 1681 on the site of the present Medical College and General Hospital; Paradis' plan seems to exhibit it and others; Governor Gyfford and his successors put in a deal of time there, but the French occupation made an end of it. Comparing maps of 1798 and 1823 to be found at the India Office, assuming the first to be complete, it would appear that there was a large addition to the number between those two dates as well as much bridge building and other improvements. In 1753, a house on the site of the present Government-house was acquired by purchase; the French occupied it in 1758, and it suffered accordingly. Thereafter it was improved and extended, the Triplicane road turned aside, and the compound enlarged. Lord Clive found it too small for his needs, appointed the Company's astronomer, Mr. Goldingham, a special engineer for the Company's buildings, made the Government-house to his mind in 1800-01, and built the Banqueting-hall in 1802. The Company were far from pleased at the adoption of "the ostentation of native Governments . . . . . the expense to which such a system would naturally lead must prove highly injurious to our commercial interests." The house improvements cost 106,000 pagodas, the hall 74,000. The latter covers a space of 203 by 111 feet; the room itself is 120 by 65 feet, and 40 feet in height; it was inaugurated on 7th October, 1802, the day being appointed one of thanksgiving for the restoration of peace, and His Excellency gave a breakfast and a ball. It is a building that impresses by its size, though Bishop Heber had not a good word to say for it, and its utility for display and social purposes is beyond question. Its walls are getting overcrowded with pictures. Budgets and Finance Secretaries put a swift and sharp curb now on "ostentation" and foot no bills that cannot

show sanction for the expenditure, so we may not look for a third Lord Clive; but Madras, not to speak of India, owes thanks to those that lived and governed as seemed good unto themselves. Guindy Lodge acquired in Sir Thomas Munro's time is the lineal successor of the Company's Garden-house of 200 years ago.

Wade's statue of King Edward the Seventh stands outside the gates of Government-house in Mount-road. The Nawab Mohamed Ali, dubbed Walajah and made independent of the Nizam in 1765, found Madras a safer or pleasanter place than his own capital of Arcot, and at one time wished to put up in the fort, but built himself a palace at Chepak in or about 1768. When Government stepped in and pensioned off the family in 1855, the land and buildings were bought in auction by Government, and enabled the Government-house compound to be extended to the sea, provided a site for the Senate-house with its magnificent hall, and gave offices to the Board of Revenue and the College of Engineering. At the south end of the Senate-house is a replica of Boehm's statue of Queen Victoria. The Public Works Secretariat, the Presidency College, the Chepak Cricket Ground, Victoria Students' Hostel, and the Gosha Hospital occupy the rest of the Palace grounds, and the Prince of Arcot now lives in the Amir Mahal in Royapetta a short distance from the Madras Club. General Neill's statue stands in Mount-road in a line with the club. He fell at the relief of Lucknow and the glory of him and of the Madras Fusiliers, as of many more, will not fade while the world has any memory for gallant deeds.

The Marina owes its existence to Sir Mountstuart Grant Duff. It runs from the Napier Bridge to San Thomé about two miles along the sea face, and was the fashionable evening resort after Cupid's Bow. Of late it has somewhat descended in use, the gentler sex finding more welcome at the Madras Club than was once accorded, and having the full liberty of the Adyar Club and grounds. The Marina leads into San Thomé with its fine new Goanese cathedral, built in 1896 over the House of St. Thomas, in which he is buried according to legend; it has a steeple 155 feet high; the diocese was created in 1606. There are many more churches and various interesting old houses in San Thomé. The ancient Mylapore, the home of successful native lawyers, with a famous temple and tank, at which there is a gorgeous yearly festival, lies behind. Further west still is the Luz Church, carrying us back to the early days of the Portuguese occupation, when they became a light to lighten the Gentiles. The Luz road debouches on the Mowbray-road, with its famed avenue of banyan trees, leading from St. George's Cathedral road and the S.P.G. Mission premises to the Adyar Club. The coast road south from San Thomé winds past the Admiralty House, now belonging to Vizianagram, where Admiral Rainier entertained the Nawab in 1805, past Brodie Castle, the bridge built by Lord Elphinstone over the river, and the ford that gave passage to Paradis and his men to the rout of Maphuz Khan and his army while the English were prisoners in their own fort, and thence on by the Adyar Club into Mount-road. Then north along it under the long tank bund past where the Cornwallis cenotaph was set up to the Horticultural Gardens, with its rarities in trees and plants, landing finally at St. George's Cathedral across the road. It also was built by de Haviland, and opened in 1815, to serve the population that dwelt far from the fort. The lottery fund contributed to its cost, as it did also to the cost of the Kirk and to other pious and charitable projects. The padre of its early days is recorded as denouncing dancing; in this, at any rate, there was an advance from the state of the times wherein good Mr. Patrick Warner had seen it his duty to bring to the notice of the directors "the vicious lives of the soldiers and some of the writers in the fort," 140 years earlier. The appointment of Bishop Corrie made it a cathedral, and Madras is proud of it.

I have spoken of the railway communications of the city. I should also note that the completion of the Buckingham Canal made a water-way from the Adyar into the Cooum, and thereby the Merkanam back water was united with the canals of the Godavari. One beneficial result must have been a readier and cheaper firewood supply from the plantations along the coast.

A word is due to the tramways. I believe they were the first electric ones in India, but they were not a profitable investment to their first shareholders. The original underground working had to be abandoned for overhead wires. They run now from the power station at Egmore to the harbour, around Vepery and into Purusawakam, through Chintadripett across Mount-road into Royapett on one hand and through Triplicane to Barber's Bridge in Mylapore on the other. Extensions are in progress. Needless to say the tramways are a

great convenience to those not served by the railway lines.

A contract for the electric lighting of part of the town was in contemplation when I was last concerned with the municipal administration, and that work may now be in progress. Telephonic communication is maintained for Government purposes, and is available for private parties who are prepared to pay for it.

The harbour is 1,000 yards square of the sea, enclosed by two arms run out from the shore doubling in towards each other and leaving an eastern entrance of 550 feet. It was approved in Lord Hobart's time; work began in 1876, and what was done was destroyed in great part in 1881 by a cyclone. It was started again after some time and, in a way, finished. The purpose was to make landing and shipping easier than the open surf permitted; safety on the Coromandel Coast is by skilled navigation through the storm. The results of damming the up and down currents of the ocean are a large and extending accretion of sand on the south, and coast erosion on the north, with considerable silting up of the enclosure. It is now proposed to revert to what I believe was the original purpose of a north-eastern entrance protected by a north-easterly arm and the closure of the present mouth. This is now in execution. Interior dredging is a necessity, and can be done with the powerful appliances of the present day. Ships are berthed throughout the basin; some can be laid up against the north groyne. The old steel pier is in the middle and in full use. Mr. Spring, the energetic and capable chairman of the Port Trust, is making improvements by new pier and crane provision for the speedier working of both imports and exports, by a seven-acre boat basin, so that more effective and valuable lighters may be introduced and worked without risk of damage to them from bad weather, and also by shedding adjacent to the piers to admit of speedier Customs disposal. The hope, of course, is of a larger trade by cheaper freights. The expenditure that has taken place and that now embarked on will, I imagine, be well over two crores. The tonnage of shipping using the port in 1905-6 was 1,519,240; it is continuously increasing. The import and export dues in the above year were Rs. 6·55. The export trade seems stationary; the improvement is in imports. The value of imports and exports was Rs. 137,127,619; the chief imports were apparel, cotton twist and yarn, cotton piece goods, grain and pulse, liquors and kerosene oil; and the chief exports, raw cotton, cotton piece goods, hides and skins, indigo, oil seeds, and ground nut. With no natural advantages of situation and as only one of several coast ports, it is not in the nature of things that trade and the staples of trade should converge at Madras as at Rangoon, Calcutta, Colombo, Bombay, and Karachi. The harbour has satisfactory uses at present, however the future may treat it, and the trustees are wisely making the most of those uses.

The administration of justice in Fort St. George in the beginning was by the fourth-in-Council, styled the Customer, who conjoined the duties also of buyer and of receiver of rents and customs. He had, for colleagues, the mint-master and the paymaster, and his court was in a building at or near the choultry gate. These Justices of the Choultry did not give satisfaction and could not overtake all the work, and in 1678 the Governor and Council determined to sit twice a week in the chapel-room to deal with the important cases.

In 1683 the Company had obtained Letters Patent for the establishment of a Court of one person learned in the civil laws to hear and determine all suits and causes with the assistance of two merchants—judgment to be according to equity and good conscience and the laws and customs of merchants. This person duly arrived, being Sir John Biggs, formerly Recorder of Portsmouth, was styled Judge Advocate, and what was called the Court of Admiralty was established. A chief object in view was the summary punishment of interlopers. An occupant of this office in 1694 was dismissed for bribery and for applying the statutes of limitation in favour of ex-Governor Yale and against the Company, but it was ordered that "due respect be given to a person of his quality and abilities in consideration of which it is a trouble to us to part with him." His offence must have been flagrant.

In 1688, when a Corporation of Mayor, Aldermen and Burgesses was appointed by the Company's orders, it was directed that the Mayor and some of the Aldermen should be Justices of the Peace and try cases, appeals lying to the Judge and Judicature of the Admiralty: in civil causes the appeal was to the President and Council. Every Englishman was to be dealt with for crime by the President or some English Justice of the Peace and not by any foreigner. A Recorder

is mentioned in the list of officers present at the institution of the Corporation in the above year, but disappears till 1798. Later, in 1688, the Mayor's Court was directed to meet once a fortnight, and Aldermen were to sit as Justices of the Choultry for petty cases twice a week, leaving the heavy cases for the Mayor's Court. Captain Hamilton's opinions on the administration of justice are very far from complimentary to the judiciary. The next reorganisation was in 1727 under letters patent; a Mayor and nine Aldermen were empowered to deal with all civil causes, with the President and Council as a Court of Appeal. The five Justices of the Peace named in the charter had the petty criminal cases as Justices of the Choultry; the President and Councillors were empowered to hold quarter sessions for all serious crimes save high treason with jurors and procedure apparently as in England. A Sheriff's Court was created with summary and ordinary powers, appeal lying to the Mayor's Court. The Sheriff was a new officer; the first appointed was the junior of the Council; he was in the inaugural procession "with a white wand, on horseback." He seems to have been vested with powers in criminal cases, but in 1729 these were withdrawn by the Company's orders. This charter was repeated in 1753, with the addition of a court of requests or of conscience for small causes. The President and Council were to create the court by appointing not less than eight nor more than twenty-four of the principal inhabitants as Commissioners.

In 1772 provincial civil and criminal courts were established for the Mufasal territories, and in 1802 the Sadr and Foujdari Adawlats were instituted as Chief Courts for the Mufasal at the Presidency.

In 1798, Sir Thomas Strange arrived as Recorder and President of the Mayor's Court of Madras town, and in 1801 became Chief Justice of a Supreme Court, with two Puisne Judges, which absorbed the Mayor's Court, and also the judicial powers of the Governor and Council so far as the town was concerned. The jurisdiction of the Small Cause Court was extended. The Supreme Court originally sat in the fort; later it moved to a house in Bentinck's buildings in the town on the sea face, and again into what were the Board of Trade buildings. Its territorial jurisdiction was, roughly, the city area; European British subjects in the country had their privileges under it. The Adawlats, latterly at any rate, occupied the Sadr gardens in the Luz. These Chief Courts were fused into the Madras High Court in 1862.

The minor administration of Criminal justice at the present day rests with the Presidency Magistrates; of Civil justice, with the Courts of Small Causes and the City Civil Court.

Police work was first performed by the Pedda Nayak and his peons, 20 in 1640, 50 in 1659, paid by *inam* (rent free) lands and by certain petty duties on comestibles. The chaplain was made secretary of a Police Board which was created in 1770, and a police court seems to have been established in 1798. The office of head Nayak was abolished in 1806, and the town police formed; and it has been remodelled from time to time since.

The history of municipal government is interesting and definite throughout. In 1675 and 1678 attempts were made to tax for improvements to the fort and keeping the town clean, but the assessees refused to pay, as they had thitherto sat tax-free and would not have that custom broken. In 1682 Child had given the council to understand that the revenue of the town must defray at least the whole constant charges, and in 1684 they half-heartedly settled to levy a small monthly tax "which if they (the townsfolk) so oppose as formerly that we cannot be successful then to offer it (propose it) as a voluntary contribution to all the inhabitants of the town, which possibly may have a better effect upon their wilful tempers." The Caste Headmen protested, but finally agreed to a graduated house tax. In 1686, however, in spite of soft words and arguments, the people broke out in mutiny, ordered the cessation of labour and service, the shops to be shut, and the bringing in of grain to be stopped, "insolently declaring that they would continue their rebellion till they were freed from the said present and all future taxes." The Council set out its soldiery, threatened confiscation of goods and house sites and eternal banishment; and firmness produced discontented submission. The Council must have been unhappy, for, six months later, Child's trenchant pen may be recognised: "This *pro* and *con* between us and you will never end well. Pray let us have no more of it. A revenue we will have *aliquo modo*, for that infinite charge we have been at to raise that town—which hereafter we shall call a city—from so despicable a condition as it was in when we settled there. . . . With your leave, we will have a ground or quit-rent yearly for every house within your precinct, and a small poll-money for every head."

In 1687 Child drafted a Corporation, for the Council's consideration, of aldermen and burgesses, who were to choose their mayor yearly, "Natives, mixed with some English freemen . . . to tax all the inhabitants for the public good, and to be so managed as to make them proud of their honour and preferment, and yet only ministerial and subservient to the ends of the Government, which, under us, is yourselves." Gowns, scarlet and black, umbrellas, maces—"silver gilt not exceeding a yard in length"—officers, and fees, were all suggested. He did not, however, wait for their opinions; orders followed in three months, and in 1688 the Corporation was in full working order. Their success as exactors and appliers of taxation was not very notable, but in 1700 they were able to levy 1,051 pagodas from the inhabitants of Black Town for a wall and other defence works. In 1726 a general survey of tenements not already under *cowle* (grant) was ordered, with a view to a better proportioned assessment and to improve the revenue from quit rent and the scavenger's duty. The town was reported on by committees for each of the three divisions. The prevailing note of the reports is the great poverty of a large proportion of the inhabitants; in Muttialpett with 1,403 houses there were not ten worth 300 pagodas each. The reporter on Peddanaikpett has a dismal tale of the foulness of the place and of street encroachments—the latter a feature of urban life throughout the Presidency that persists to the present day in spite of penalties under the law. The purpose of improving the revenue was very little served. Prior to 1735 what was called the Town Conicopoly's duty was appropriated to the repair of bridges, but the directors ordered it to be passed to the credit of their revenues and the council fought shy of special assessments or tolls, preferring when the bridges had to be repaired to charge it to general revenues.

Acts of the Georges gave powers to the Justices of the Peace assembled at General and Quarter Sessions to arrange for the cleansing, watching and repairing of the streets of the Presidency towns, and to levy a house and land assessment. A string of Acts of the Government of India and of the Government of Madras from 1836 onward, sanctioning increased and extended taxation, appointing paid Commissioners, associating honorary Commissioners with them, creating divisions of the city and local representation, directing provision for education, hospitals and vaccination, introducing the elective principle and extending it, lands us finally at the present Act III. of 1904. That was framed somewhat on the model of the Calcutta Municipal Act, and created a representation of 20 elected ward Commissioners, one for each ward, of eight more nominated by public bodies—the Chamber of Commerce, the Trades Association, the Harbour Trustees and the Railways—and of eight nominated by Government. The standing committee—the working body—consists of eight members and the President, composed so as to produce the Corporation constitution in miniature. Amplified borrowing powers were given; the maximum of taxation on lands and buildings increased from 15½ to 18¾ per cent., and improvements on the prior law in various respects and specially in the regulation of buildings were introduced. The voting qualification, so far as it is monetary, is payment of a particular taxation of Rs. 20 per annum or householding to that value per month, while Commissioners must be of the male sex, twenty-five years old, acquainted with English, resident in or within two miles of the city, paying Rs. 100 per annum in taxes or occupying a house of the annual value of Rs. 1,200. For the introduction of the Act the lists showed 441 persons qualified to be municipal commissioners, and 6,524 qualified to vote at elections. Sixty-five per cent of those qualified to vote did so at the first elections.

Profession tax, animal and vehicle tax, and tolls are imposed as well as the house and land taxes. These in 1904-5 yielded about 11·50 lakhs; other receipts made up an income of 17·14. They spent on public new works 6·29 of which 5·86 was for drainage, on repairs 5·04; on education ·07 apart from the Government subsidy; on hospitals and dispensaries, vaccination, registration and conservancy 4·16; on lighting, markets, avenues, parks, &c., 2·26; for supervision ·94. Sinking fund payments aggregated ·75, and interest on 60 of debt was 2·63. The sinking fund accumulations amounted to 18·43. The Corporation has been able to borrow for the past ten years at 4 per cent.

The works that have tried its finance and engineering abilities are, as may be supposed, water supply and drainage. Over thirty years ago two irrigation tanks beyond the Red Hills—a lateritic outcrop eight miles from the fort—with a combined water-spread of ten square miles were taken and strengthened; a supply channel was cut from the Kusastala

(Corteliar) river nine miles north of the Red Hills tank to convey flood water to increase the local rainfall supply; the amount for irrigation from the tanks was restricted, and the surplus made available for Madras by gravitation along an open channel to Kilpak, whence it is distributed in pipes throughout the town. When the lake level falls to about 36 above mean sea-level pumping has to be resorted to in order to pass water into the channel, and this happens late or early after the north-east monsoon according to its copiousness or otherwise. It is not an ideal supply or delivery by any means, but is a great advance on the old well supply; its defects are possible deficiency, lift from the tank bed, local fouling, non-filtration and lack of pressure which, in particular is now causing fouling of the distribution pipes. It is in view to take off from the lake at a lower level, to cover in the supply channel, provide filter beds and lift the service at the city delivery to secure pressure and a wider distribution. The supply of 1904-5 was 625,000,000 cubic feet—a rate of about 20 gallons per head per diem but so much never reaches the individual. The scheme under present consideration is for a population of 660,000 at 25 gallons per head per diem. And the cost of it will not be less than 25 lakhs, while a thorough distribution service will mean a good deal more.

The drainage of 27 square miles of land but little above sea-level is a more difficult business. Since sewage is properly transmitted only underground and the question is one of slope the problem requires no further statement. There has been no lack of advice or of schemes. The plan finally adopted was to deal with the city in sections, pumping on to sewage farms, and Black Town was so treated in the eighties at a cost of about ten lakhs. Five other sections have been undertaken, and the present purpose is to collect the sewage in each division at a well and lift it by pumping into a main that runs from Mylapore, through Triplicane, Chintadripett, the People's Park, across the railway and the canal, and over the Trivetore High-road to the Tondiarpett Farm, which is intended to receive the whole flow. At the present moment the sanitary authorities have condemned the execution throughout; the Corporation is not disposed to accept this judgment without further evidence, and is taking time for more observation and for local experiment. The points for notice are that the gradients of the main are seemingly insufficient for proper onward movement, and that the tota execution has so lagged that already the provision is behind the time. With a largely increased water supply in near prospect and a twelve per cent. increase of population every ten years, it behoves those concerned and responsible to see that their duties towards the present and a near future at least are passably fulfilled. Till the present time 31·4 lakhs have been expended out of an estimate of 48 lakhs; now it is conjectured that 85 lakhs will be the total cost of a proper service. It is impossible for Madras to undertake work of such magnitude out of its own resources; past errors are due to its having to cut its coat according to its cloth and to restrict its output of work to the funds available. The Supreme Government controls the only purse that is equal to such occasions, and it instructs the local Government that local municipal wants are debitable to local municipal income. The principle is excellent; wisdom has regard to the particular instance when it is sought to apply any principle.

The health of the city varies largely from year to year. The congested parts naturally suffer in comparison with the free and open blocks on the margins and in the south; epidemics when virulent alter normal figures largely; and scarcity outside will cause an influx of bad lives and swell the death-rate, while a heavy monsoon will log the soil further and set up fevers. The average birth-rate is fairly constant, being around 40 per mille for the ten years 1894-1903; for the same period the deaths average 41 because of large excesses in the rate in three years. And for 1905-6 the birth-rate was 45·6 and the death-rate 59—the largest on record save for the famine year 1877, when it was 117 per thousand. There were outbreaks of cholera and small-pox and a large infantile mortality in 1905-6.

Plague has been most successfully combated —it may be said kept out—till very recently, and even now cases are few; the dealing with it is both worrying and expensive.

The continuing increase of population is due to immigration. The proportions of race are 806 Hindus, 113 Mussulmans, and 80 Christians in a thousand, and of literates, that is of those that can read and write a letter, 360 in 1,000 males and 91 in 1,000 females, as against 119 and 9 for the Presidency.

The mean rainfall over 90 years is 49·11 inches per annum, mean temperature 82°, with extremes of 64° and 108°. In May and June,

said Thomas Bowrey in 1688, it is "something sulphurous," but perhaps August and September are more trying by their damp heat.

Recent visitors to Madras have spoken of it in kindly fashion. The character of the place and of its people could not have been more cordially recognised and appreciated than by its Royal and many visitors of last year, when Lord and Lady Ampthill did the honours of the Presidency magnificently and gracefully. Still the carping critic of the North will talk and write of it as "a pleasant backwater," "a country that needs no talents in its administration"; and five years ago the Society of Arts was informed that "there is no city of Madras, only an obsolescent maritime cantonment with no future and consequently no past of the slightest interest." My heart sank at the nature of the instruction you—once at least—have received. I would fain make no contrasts, but Madras has no mighty river flowing past, no supremely fertile soil adjacent, no splendid bay, no hills to look up to or from. She has achieved what men and nations struggle for—peace and prosperity; a contented people, a Government that busies itself with adjusting land and other taxation equitably, improving the conditions of life, developing the resources of the country, and adding to the revenues of the Empire to help it towards the same goal: pleased if she is now and again permitted to retain for herself a little more of the large revenues she affords. In irrigation and in many things else she has set object-lessons to the Empire; if others have bettered the instruction they have to thank their larger opportunities. I am travelling away from the City of Madras, but the city is the microcosm of the Presidency, and houses the Government for half the year. The city is loyal, and is not asleep; it thinks and speaks without shouting *Bande mataram* or other ridiculousness, with a sobriety and common sense to be envied and imitated. Neither Day nor anyone else of his time looking on that starveling spit of grey sand, on the wretched Cooum—with a bar that closes from February to October if a cyclone does not open it—and on the tiny villages dotted about the flat infertile plain towards the west, could have dreamt of a future when over half-a-million would dwell there pursuing industrious callings, provided with the civilising agencies which this century affords and with no Nayak, Nawab, Nizam, or Great Mogul to make them afraid. The storm and stress of war, glorious and inglorious, has gone long years ago; a struggle of another sort is now afoot in Madras as elsewhere, to be dealt with by statesmanship not by battalions, for the settlement of which self-reverence, self-knowledge, self-control on all hands are prime requisites.

To me the marvel of the city is that with so little granted by natural position so much has been accomplished. Destitute of the usual foundations of a great city she is still the third in India, and the fact says much for the strong hearts of her makers and begetters. In trusting that she will continue to flourish I am certainly voicing the wishes of all that have had a home there and have kuown her as she deserves to be known.

DISCUSSION.

The CHAIRMAN was sure everybody present would agree with him that they had listened to a highly interesting paper. He had been particularly struck by a remark made by Sir James in his closing sentences concerning a former paper read to the Society. He did not know who the author was, but he had apparently said that there was no city of Madras. Sir James Thomson had stated that Madras was still, as regards size, the third city in India, and he believed he was right in saying that it was, in that respect, the seventh city in the British Empire. It was quite possible, from one point of view, to assert that there was no city of Madras. If one ascended to the top of the Law Courts, the highest point in the town, and looked round, no city could be seen; the aspect was was more like that of a forest than that of a city. From that point of view, and that point of view alone, it was possible to assert there was no city of Madras, so luxuriant was the vegetation which constituted one of the principal charms of Madras. The author, as was right and becoming to one who read a paper to a learned Society, had filled it up with a great mass of historical, archœological, and political matter; and, interesting though that was, it could not give anyone an idea of the charms of the city of Madras; indeed, it was impossible for anybody to realise those charms unless they went and saw for themselves. He was not speaking in the spirit of the Scotchman, who, after travelling all over the world and seeing its great sights, declared that in his opinion there was still no place like Peebles. He (Lord Ampthill) was not a native of Madras, but still he said advisedly, having lived there for five years, that there was no city in the world for which he had a greater or more real affection. Places were judged not only by their natural charms, but also and more particularly by the people that inhabited them. He need say little of the European society of Madras, for English people are the same all the world over, but he would like to pay his tribute of affection to the Indian community. The nature of the people of Madras was never more

clearly evidenced than when their Royal Highnesses the Prince and Princess of Wales paid a visit there. It was a scene which he personally would never forget. Every coign of vantage, every inch of road, was crowded with a happy throng, on whose faces genuine pleasure and delight were depicted. He had never seen any crowd anywhere which displayed such genuine good humour, contentment and happiness as the crowd at Madras did on that occasion. But that was not unusual. If one drove through the crowded bazaars of Madras, it was generally noticeable that the mass of the people had smiling and contented faces. Of course, poverty and misery existed, as in all great cities, but still the general impression a visitor took away if he went through the crowded quarters of Madras was, that the population was as contented as a large city population could be anywhere. In addition, he derived a very great pleasure from association, in many concerns, with the educated section of society. He could not detain the meeting by describing their views, habits, or customs; it would suffice if he reiterated what the author had said about them, namely, that they were the most level-headed section of the peoples of India. They possessed the qualities of common-sense, of moderation in public affairs, and of soundness of judgment more than any other class in India. The important thing to remember about Madras was that it was the first foothold of the British Empire in India. The paper did not afford any occasion for discussion; there was no room for difference of opinion in regard to matters which were purely description; but Sir Philip Hutchins, a former member of the Madras Civil Service who held the high office of a Judge in the High Court, was present, and he was sure the audience would like to hear whether his recollections of Madras, which no doubt were as pleasant as those which the author and he himself had retained, had remained fresh and green in his memory.

Sir PHILIP HUTCHINS, K.C.S.I., remarked that Sir James Thomson had dealt so fully with the subject that he was in some doubt as to what aspect of the question he could take up. The audience certainly would not wish to hear anything more about the ancient history of Madras; but, following the lead of their noble Chairman, he would venture to amplify what had been said about the present amenities of the city compared with the other Presidency towns and Rangoon. Madras did not possess a grand natural harbour such as Bombay had, nor had it any deep water river such as there was at Calcutta and Rangoon. That was a great handicap to its commerce, but if he were told that he must take up his permanent abode in any of those places, having some little knowledge of them all, he would, on the whole, choose Madras. Its climate certainly was warm, and it had no real cold weather, but neither had Bombay nor Rangoon. Although warm the climate was equable, and the hottest months were tempered by a pleasant and invigorating breeze from the sea, which began early in the afternoon and continued till about midnight. In addition, as the author had stated, Madras still enjoyed its garden houses, well-built commodious dwellings with wide verandahs, and walls faced with fine shell plaster which might very well pass muster as the finest white marble. And those houses were to be obtained at a very moderate rent, which was very far from being the case at any of the other places he had mentioned. In other respects also Madras was certainly a much cheaper place. Many of the gardens or compounds might even be worthy of being called parks; some of them, as the author had stated, having their own private golf links. There were many miles of excellent roads and lovely avenues of banyans chiefly, but of other trees also. There was fair boating on the Adyar close to the Sports Club, and along the many miles of road there was capital riding. Madras, certainly in his own time and he believed still, maintained its pack of hounds all through at least the cooler months. The servants of Madras were admirable. The best of them did not leave the Presidency, so that anyone who did not know Madras did now know how admirable the Madras servants were. As the Chairman had stated, the educated classes were loyal and intelligent, and were very agreeable companions; he had still very many friends among them. Last of all, there was the Madras Club, which, by general consent, was, and always had been, the very best in India. Perhaps some of those present had heard that Madras had had a very scornful epithet applied to it, and would, therefore, wonder whether what he was stating was strictly correct. He had already alluded to the absence of a perfectly satisfactory harbour. Madras had no land frontier involving frequent and costly expeditions, and the people were orderly and quiet. Therefore, in the circumstances, it was natural that the wheels of Government should run more smoothly in Madras than they did on the north-west frontier, or in the country of the discontented Mahratta, or of the loquacious and irrepressible Babu. In that sense, and that sense only, he was prepared to admit that Madras was a placid place; but that was a very different thing from being benighted. It might be thought that he was prejudiced on the subject, and he confessed his sympathies naturally were with his own Presidency; but he would call an independent witness. It would be remembered that, some few years ago, the leading newspapers in this country sent out special correspondents to the Delhi Durbar. One of them found his way to Madras; he investigated the disparaging epithet which had been used about the city, and, after saying very much what he (Sir Philip Hutchins) had said about the smoothness of the wheels of Government, he wrote as follows:—"Madras, therefore, deserves the happiness of a country which has no history. Our ultimate aim being the protection and well-being of the natives, the almost practical attainment of this aim has been secured in Madras, and has robbed our work

there of much of the spice and zest which excite enthusiasm. The administration has been brought to a state of easy-running which tempts less happy Provinces to gaze wistfully to the South." A country that could be so described by an independent critic could hardly be called "benighted." He would venture also to cite one other witness, no less a person than their noble Chairman, who, in some very felicitous words which he once addressed to his Legislative Council, said :— "We in Madras are happily free from any necessity of considering heroic measures of reform. The existence of any necessity for great reforms connotes the existence of great evils; and, satisfactory though it is to have great reforms carried out, it is a happier condition not to need them." As he had already said, the audience might consider him prejudiced, and he acknowledged he was biassed; but after five years' work in the Governor-General's Council, and a still longer period at the India Office, he was quite satisfied that Madras need not fear comparison, and had indeed a great deal to be proud of.

On the motion of the CHAIRMAN, a hearty vote of thanks was accorded to the author for his admirable paper, which Sir James Thomson briefly acknowledged.

Sir STEUART COLVIN BAYLEY, K.C.S.I., C.I.E., said it was not usual at the meetings of the Society to pass a formal vote of thanks to the Chairman; but he felt sure he was only expressing the feelings of all present in saying that not only they but the Society were very grateful to Lord Ampthill for his kindness in presiding over the meeting; and he said that, not only for the great majority of the audience, but also for that miserable section of it which had not the felicity of being Madrasees.

Mr. R. F. CHISHOLM, F.R.I.B.A., Consulting Architect to the Government of Madras (Retired), writes:—Sir James Thomson's much appreciated paper made those of his audience who had lived in the city again feel its pleasant sea breezes; but it was with a pang of regret I learned from him how serious an effect that same sea breeze seems to have had on the past and future of the city! Speaking of its harbour, Sir James Thomson said :—

"The results of damming the up and down currents of the ocean are a large and extending accretion of sand on the south, and coast erosion on the north, with considerable silting up of the enclosure," and again "interior dredging is a necessity." Further on Sir James says :—"With no natural advantages of situation, and as only one of several coast ports, it is not in the nature of things that trade and the staples of trade should converge at Madras as at Rangoon, Calcutta, Colombo, Bombay, and Karrachi."

This is the truth, and if the truth, why this vast expenditure? Was it because this truth gradually dawned on a section of the merchants of Madras some years ago that they sought at all hazards to commit the Imperial Government to this useless waste of money? If Madras could be made a port it would be the centre of trade for the richest districts in India; if, on the other hand, it could not be made into a port, the era of railways must sound its death knell. Madras may be the Brighton and the Oxford and Cambridge of India, but the port, never! It may stretch its northern arm along the coast northwards until it reaches Coconada, it may, in the mean time, fare sumptuously on the crores of Imperial expenditure sunk in the sea during the process, but if such a thing were really possible then Coconada would be the port, not Madras.

When I first became acquainted with Madras in 1863 it possessed one of the finest open roadsteads in the world. It was a favouite port of call for both ships and steamers trading with Calcutta; it was the centre of the passenger traffic for the whole of southern India. Being an open roadstead, the port dues were so light, that a vessel could touch even to get rid of a ton of cargo. For ten months of the year and sometimes the whole year, landing and embarking were perfectly safe. During the two cyclone months, May and November, the communication between the ships and the shore might be doubtful, but with proper precautions no ship should ever be wrecked. This bold statement requires explanation. I was present at the great cyclone of 1872-3, I forget the exact date, and saw sixteen ships wrecked. They were all driven on shore because they were lying within the line of partially progressive waves, and the successive blows from such immense masses of moving water no ship's cable can stand. One full rigged ship, the *Inverness*, anchored in about 11 fathoms, rode out the cyclone comfortably. I made a point of seeing the captain of the *Inverness* before she left the port, and he assured me that the cyclone was no worse than an ordinary bad channel gale. Few captains take into consideration this extra progressive action of the tops of waves on a shelving shore after a series of calms—the recent wreck of the *Berlin* on the Hook seems to be a case in point. If a powerful tug had been kept at Madras to tow ships to a safe anchorage during bad weather no well-found ship would have been lost.

It may not be out of place to explain briefly why a harbour cannot be made at Madras. The coast line consists of a broad belt of moving sand. Every particle of this mass is always in motion. In the south-west monsoon the particles move northwards, in the north-east monsoon, southwards, during heavy weather, in-shore, during calms, seawards, as all the particles are performing this catenary curve movement the coast line is maintained. Now, obstruct this movement in a line at right angles to the coast line, and during the south-east monsoon the south angle will fill up and the coast line north erode,

and during the north-east monsoon the north corner will fill and the south coast erode, and this is exactly what has occurred, accretion on the one side and erosion on the other. The expert who advised the Government admitted the probability of this action, but said that it was of a continually decreasing nature, and that before the sand passed round the end of the arm a constant would have been arrived at. This prediction has not been fulfilled. Not only has the sand worked round the outer wall, but it is filling the harbour which will "have to be dredged." It seems to be a reliable conclusion that if thirty years ago the effects as we see them now had been anticipated, no harbour would have been made, and although closing the central entrance and extending the north arm will materially lengthen the days of the harbour, what has been, will be, in spite of all dredging the harbour will close by silting, if some worse calamity does not seal the fate of the city, for it is quite possible for the erosion north to re-open the old backwater, and Madras may then share the fate of Mahavillapoorum, the submerged city higher up the coast which figures in Southey's "Curse of Gehenna."

THE BRITISH INDIAN COMMERCIAL MISSION TO SOUTH-EASTERN PERSIA.

I.

On account of the great importance of the report on Mr. A. H. Gleadowe - Newcomen's Commercial Mission to Persia, and the difficulty of obtaining copies, the following summary of the chief contents of the report has been prepared. The report has been printed by the Superintendent of Government Printing at Calcutta, and issued in the form of one of the usual Indian official publications, but the Indian Foreign Office have explained that the remarks and opinions are not official and rest on the authority of Mr. Gleadowe-Newcomen.

Copies of the report are said to be obtainable from the Upper India Chamber of Commerce, Cawnpore.

There is one point that must be borne in mind, and that is, that since the completion of the report, there has been a very marked movement in Persia (comparable with that in China, with whose circumstances Persia has several curiously similar points of analogy) in favour of "Persia for the Persians." This is not referred to by Mr. Gleadowe-Newcomen, but must affect the situation. Indeed it has already done so, so it appears, within the last few weeks, in bringing about the dismissal of two Belgian officials in charge of the Customs and probably of those in charge of the Posts as well.

The Origin and Objects of the Mission.

The genesis of the Mission lay in the fact that when the itinerary of Mr. Maclean, the Special Commissioner, appointed by the Commercial Intelligence Committee of the Board of Trade to inquire into British trade with Persia, was published in 1903, it was observed that the important mart of Yezd in Central Persia, and all the south-east part of the country were omitted. At the suggestion of Major Sykes, C.M.G., then H.M. Consul in Kerman, Lord Curzon determined on the despatch of a commercial mission to the region in question. Unfortunately no engineer was attached to the expedition, a regrettable decision as the absence of roads and the urgent need of the improvement and extension of irrigation would have made the observations of an expert valuable. The Upper India Chamber of Commerce and the Indian Tea Association Committee, lent assistance, and Mr. Gleadowe-Newcomen was appointed President, his colleagues being Mr. B. E. Luffman and Mr. P. F. Ryan, the latter acting as secretary.

The chief object of the Mission was—

1. An investigation of the present state of the trade of south-east Persia.
2. Examination of the hindrances to reasonable expansion of trade, especially with India, and of the causes of shrinkage.
3. How to expand Indo-Persian trade.
4. Introduction to Persians of Indian manufactures.
5. Collection of statistics.

The route as originally sketched by the Government of India was:—Northwards from Bander Abbas to Sirjan and Kerman and neighbouring tracts and thence through the Bampur Valley and Persian Baluchistan, Kuhak and the Kej Valley to Gwadur or Pasni on the coast, and thence home. As, however, there was no engineer attached to the Mission, it was decided that there was no hope of fostering much trade in the sterile parts, so a more extended tour was made in Persia proper as far north as Yezd.

The departure of the Mission took place on the 13th October, 1904, from Bombay for Maskat. At the latter port the party transhipped for Bander Abbas, where they arrived on the 21st October. Here the Mission appear to have been a good deal obstructed by the Belgian Director of Customs, notwithstanding the fact that special orders had been sent from Teheran for all facilities to be afforded. Things have since improved, for a British Consul has now been appointed, who is showing keenness in his protection of our country's interests.

Physical Features of Persia.

With the exception of a narrow sub-tropical strip along the coast, south-eastern Persia is a country with a fairly temperate climate. Even Persian Baluchistan and the terrible Lut desert are cool in the spring and autumn, and often cold in winter. In the low country (called the Garmsir), Jiruft, Persian Baluchistan, Bam-Narmashir, the Bushire plain and the oases in the lower and southern part of the plateau, tropical fruits, such as the date, lemon, and orange flourish, and even mangoes are sometimes met with; rice and tropical cereals are also grown. In the higher and colder regions, fruit and grain of the temperate climates succeed well.

The proportion of cultivated and cultivable land to wilderness and desert is small, however, and there are evident signs that it is steadily shrinking. Yet if irrigation, on a large scale and scientifically directed, were carried on, it would be possible to reclaim a considerable portion of this desert, for the soil is naturally fertile, though much of the water is brackish. Geographically, southern and eastern Persia may be described as a land of mountain and deserts. A few miles (15 to 30) from the sea coast, the great mountain ranges that rib Persia, raise their bare and splintered walls to the sky. Stretching their snow-capped tops, range after range, all along and across the land for hundreds of miles, they throw out great spurs which touch one another. Between the treeless ridges lie valleys, often of great length, some of them 30 and some 300 miles long, but seldom of any great width. Most of these valleys are capable of cultivation with the help of irrigation. In the gorges of the hills, and built along the banks of occasional streams, are rare villages, nestling in plantations of fruit trees. Other trees are scarce; what forest once existed has disappeared, and as a partial consequence, the rainfall, judging from the numerous dry river beds, has decreased. Rivers no longer flow except immediately after rain, and then the waters, after coursing in mad fury, are soon lost in the desert, being won again with infinite labour back to the fields by means of subterranean canals called *Kanat* in south-east Persia, and *Karez* in Afghanistan and Baluchistan. These canals run from distances of 10, 20, 30, and even 40 miles down into the valley.

The villages as a rule are small, and occur at considerable distances, and even the important cities like Kerman, the provincial capital, are not particularly prosperous. Yezd has lost much of the camping trade that made it rich, while the trade of Shiraz does not increase.

The People.

The Persian peasantry and the nomad tribes, the latter, mostly of Turki, Kurdish, Baluch and Arab extraction, are people of good physique, but the town folk are not. The heart of the nation was broken centuries ago, and now owing to its brains and manhood being sapped by opium and unrestrained vice, the state of Persia is pitiable, notwithstanding the natural intelligence of the people. Almost every office in Persia from the highest to the lowest is farmed out for a year, generally speaking, in which period the farmer or contractor has to recoup himself two or threefold (there is no fixed taxation or limit to demands) for the expense he was put to in obtaining the post. Khans, peasants, and traders (especially the last) pay two tomans, where in ordinary circumstances but one is exacted, and if they demur, a short cut is found to their pockets through the soles of their feet.

Unless some drastic changes are made in the system of government, any considerable or speedy change in the condition of the people and consequently in the trade seems hopeless. Our chief chance lies in persuading Indian traders (British subjects) to settle in Persia, and this they will do if they know they have consular protection at hand.

The Persian differs widely from the native of India, who, whatever he may spend on occasions of mourning or rejoicing is, whether Hindu, Sikh, or Musalman, a man of few wants and frugal to a degree. The Persian is not a man of frugal mind. He resembles the European and especially the Englishman in his preference for putting the money he earns on his back or into the stomach, and rejoices in good food and good clothes. The humblest Persian dresses and eats well; few men in rags are to be seen except among the poorest peasants and the professional beggars. He has a craving for the luxurious and showy, and though he himself dresses in sober colours, and his women-folk in the streets resemble sheeted ghosts, for the peculiar indoor dresses of the latter and for the adornment of his house he rejoices in gay prints and cretonnes, bright hued silks and rich satins. Like the native of India, he revels in looking-glasses, lamps, coloured-glass pendants, bright china, clocks, watches, knives, and European gimcracks. The floors of his house are, as a rule, carpeted with exquisite gems from the loom, which give evidence of considerable taste. He is a great drinker of tea, which he makes and drinks after the Russian manner, and his consumption of sugar, which he procures from France, Russia, Austria, and Egypt, is enormous.

The constantly increasing consumption of opium which is smoked as well as eaten induces a considerable increase in the demand for tea. It is a fact that opium has a far worse and more rapid effect on the Persian than on the Osmanli, the Indian, or the Chinaman. This is doubtless due mainly to the very impure nature of the drug, which is home manufactured and much adulterated. The opium habit is generally contracted in the season of fasting, when it is taken as a medicine. Once begun the Persian can never give it up; he goes from bad to worse, becomes a wreck in two or three years and generally dies in five or six years. Nevertheless, under a better system of provincial Government, the Persian might be given a fair chance in his own country and improvement in trade with India result. At present his knowledge of India is confined to one word, Bombay, while in default of familiarity with Indian products, money is squandered on silver horse trappings and other finery.

Among hindrances to trade may be mentioned the lack of bonded warehouses, and proper communication (road, postal, and telegraphic) as well as the safety of goods in transit. The balance of trade again is unduly heavy against Persia. The exports from South Eastern Persia into India, for instance, are too small to set off against imports from India into Persia. Unable to pay for imports by the sale of exports, Persian importers have to do most of their business in cash,

and their transactions being thus limited, they feel seriously the effects of the least disturbance in exchange. At the same time Indian traders fail to get the benefit of the appreciation of the rupee, for they cannot save in bank commission on the return of funds, neither can they profit by extensive purchases of Persian products in a cheapened market. Another reason is the apathy and ignorance of Persia and of its requirements prevailing among Indian traders.

Mr. Gleadowe-Newcomen here remarks that considering the exactions of provincial rulers, the indolent conservativeness of Mohammedan traders, the state of Persian commercial law (as regards the creditor especially) and the new Customs tariff, which doubles the price of a necessity like tea, not to mention the unjust clauses of the Règlement, he is surprised that matters, commercially speaking, are not worse than they are.

A great advantage possessed by the Russian manufacturers is that they cater for the wants of a population whose wants resemble those of a great part of the Russians themselves. The Indian producer must, therefore, study what the Persians want and set himself to supply exactly these requirements. Advantage, too, might be taken of the presence in India of certain Persian youths oi good family, who are being educated there, to be taken on tour in the winter months and shown everything in the manufacturing centres.

INDUSTRIAL ART EDUCATION IN FRANCE.

The principal industrial art schools in France, where the future artisans who are to continue the high traditions of artistic manufacture are educated and prepared for their work, are the following:—The Germain Pilon School. This is situated in a quarter mainly inhabited by small manufacturers and their workmen, and receives only day pupils. The normal age of admission is fourteen years, but boys of exceptional ability may be admitted when a year younger, provided they have obtained a "certificate of elementary studies" at a communal school. There is no formal entrance examination, but the candidate is required to execute a geometrical drawing to demonstrate his artistic aptitude, and write a short composition to show his degree of knowledge and general intelligence. The course of instruction lasts three years, and is thus divided:—First year—geometry, decoration, architecture, water colour, sepia, and black and white drawing, and modelling. Second year—perspective, anatomy, and geometrical drawing in sepia, ornamental designs for braids and trimmings, designs for furniture, the history of modern art, modelling and moulding. Third year—the same as the second, with the addition of decorative composition and study of standard styles of art. Students on leaving this school generally enter the workshops of some of the great furniture makers and decorators of Paris and the provinces, where, according to the American Consul-General at Paris, they earn at first about £4 per month, but they are always in demand and their promotion is certain and rapid.

The Bernard Palissy School, named after the great ceramic artist of the sixteenth century, may be considered a branch of the Germain Pilon School, above described, and is specially intended for the education of young men for certain industries, the designing and decoration of porcelain, designing of textile fabrics, carving and sculpture in wood, metals and stone. Only pupils of French nationality are admitted. The candidate must be fully thirteen years of age, and must reside in the Department of the Seine, and must pass an entrance examination in reading, writing, history and drawing. The course includes four years, during the first of which the pupils continue the ordinary studies, such as grammar, geography, arithmetic and history, as well as modelling, drawing flowers, lineal drawing and ornamental designing. They are taken in classes to visit various workshops and studios, where they watch the finished artisans at their work and choose each for himself what branch of industrial art he will follow. In addition to the practical work in each division, the study of the three final years comprises decorative composition, drawing from plaster casts, the human figure, modelling, perspective, the theory and history of art, and analysis of styles. There are at present in this school thirteen masters and one hundred and thirty-two pupils, divided as to choice of profession as follows:—Twenty-five decorators, twenty designers of textile fabrics, twenty sculptors in wood, ivory, and stone, sixteen porcelain painters, and fifty-one pupils in the first year who have not decided upon their special line of study. From this school come many of the leading decorative painters, textile designers, and artisan sculptors. The cost of maintaining these two schools is about £4,400 per annum, and they turn out altogether about sixty graduates each year.

Next in order, and a step lower in the scale of art industry, come two schools which are specially devoted to instruction in certain handicrafts pertaining to special industries. These are the Estienne School, in which are taught all the arts connected with the production of books, viz., artistic typography, binding, engraving on wood, metal and stone, photography and photogravure. The school was named after a celebrated family of printers, the first of whom, Henri Estienne, was born in 1470, and founded an important printing and publishing house about 1502, which remained at the head of the artistic publishing houses in Paris for upwards of 350 years. Applicants for admission to the "Ecole Estienne" must be of French nationality, not less than thirteen, or more than sixteen years of age, and resident in the city or suburbs of Paris. If the pupil lives in one of the suburbs (outside the fortifi-

HOME INDUSTRIES.

Cotton Supplies.—It looks as if the cotton crop of the present year will be equal to, if not larger, than the record crop, 1904-5. The returns of the Census Bureau giving the total amount of cotton ginned from the present crop up to the 15th inst., is 13,290,000 bales, in comparison with 10,697,000 bales last year, and 13,504,000 bales in 1904-5. At the same date the amount of cotton in sight was 11,590,000 bales, as against 9,086,000 last year, and 10,076,000 in 1904-5. But whilst the quantity exceeds the most sanguine estimates of the experts, the quality leaves much to be desired. The chief cloud in the sky just now is the growing friction between employers and employed, the demand of the hands for higher wages. But it may be hoped that an amicable settlement will be arranged.

Transport Charges and the Public.—Signs are not wanting that the time is near when the public will have to pay more for their transport over London. Whatever the cause, there can be no doubt whatever that the companies engaged in the transport of the public are doing badly. It is not that the public travel less than they did—there was never a time when so many passengers were carried—it is that carriage under present conditions does not pay. "All companies engaged in carrying passengers in London were," said the chairman of the District Railway Company at its recent general meeting, "if not losing money apparently making no profit." The Metropolitan and Metropolitan District Railways, now electrically equipped at a cost of over £3,000,000, are doing badly. The one has had to reduce its dividend for the six months ended December last from 2¼ per cent. to ½ per cent., and the other has a large deficit to face in its interest charges, having worked at a serious loss throughout the year. The Tube lines are making only small profits where they are making any. The Central London, particularly well placed, and with no expensive junctions, &c. to work, only pays four per cent. to its shareholders, and the City and South London just half that rate, whilst the Baker-street and Waterloo has failed to earn its full debenture charges, the Great Northern and City is a long way from making the profit required to pay a fair return upon its capital, and the Piccadilly and Brompton promises badly. Nor is the position of the omnibus companies more promising. One of the great horse companies has passed its dividend, and the other paid a reduced dividend which some shareholders consider ought not to have been distributed. It is claimed for the Municipal Tramways Systems that they pay well, but without fuller information than is available to the public, the actual position is doubtful, whilst the outlook for the motor omnibus is anything but promising, and experts affirm with confidence that if proper allowance were made for depreciation, it would be shown that not one of the lines, or at most only one of them, is being run at a profit. The capital of the chief passenger carriers of the metropolitan area amounts to some £47,000,000, and, after meeting fixed charges, the surplus profit, if distributed equally, would give a return of ¾ per cent. per annum only on this immense capital.

Workmen's Trains and Railway Investments.—Of course the transitional period through which London's transport system is passing has something to do with the poor results enumerated above, but when due allowance is made for this, it seems difficult to avoid the conclusion that fares require readjustment. The average fare is 1½d., and it it only the companies which approximate to 2d. per passenger—the Central and City and South London—that hold out the promise of something like a fair return upon capital. It was expected that the electrification of the underground lines would enable them to be worked at a much less cost, and, assuming this, there was a reduction of fares which compelled a reduction on other electrical systems, but which already has had to be modified, there having been serious miscalculation as to cost. Then the workmen's trains are a heavy loss. On the District Railway, where the workmen's traffic constitutes about 30 per cent. of the total traffic carried, the average receipt per passenger from workmen's train traffic is given by the Chairman of the Company as 0·65, whilst the cost of conveyance per passenger is stated to be 1·22. This question of workmen's trains is unimportant in the case of a large trunk line railway where the loss upon the workmen's trains is a comparatively small matter, the proportion to the whole business done being insignificant, but it is very different with the small local lines like the Metropolitan and Metropolitan District. It may be gathered from recent speeches of the President of the Board of Trade that he is fully alive to the difficulties under which the Companies dealing with the Metropolitan passenger traffic have to work. Speaking on the Railway (Contracts) Bill he gave it as his opinion that nothing should be done to make railway investments so unremunerative that the Companies could not get money for the purposes of development. What is wanted, amongst other things, is the establishment of a Traffic Board as recommended by a Royal Commission, and more harmonious working amongst the interests concerned. The public cannot be in the long run gainers by fares that spell loss to the carriers.

The Port of London.—The London and India Docks Bill comes up for second reading in the House of Commons on April 16th, and there is some hope, although at present it would seem to rest on no very solid foundation, that the Government may consent to make it a Ministerial measure. The President of the Board of Trade has said that he cannot tackle the very thorny problem of the Port of London till the Session of 1908, when he will seek to create a Port Trust to take over the existing dock companies and reorganise the Port generally. But the London and

India Docks Bill is receiving much support, and conceivably it might be amended on lines that would commend very general support. It gives the Port an authority to levy the dues on imported goods which is imperative if the money necessary to extend the docks and improve the river is to be found without a municipal subsidy, which would mean municipal control, and it does away with the "free water" rights of barges, two vital changes both of which were approved and recommended by the Royal Commission of 1902. Whether or not the Government see their way to support the London and India Docks' Bill, amended in various ways—and perhaps it is too much to expect them to add a London Port Bill to the present long list of Government measures for the Session—it is earnestly to be hoped that they will deal with this matter next Session. It is admitted that much money must be spent on the river and docks if London is to maintain her pride of place among ports, and spent without much longer delay.

Private Wires and the Post Office.—On Wednesday of last week Mr. Justice Swinfen-Eady gave an important judgment in a matter of considerable moment to shareholders in the National Telephone Company. By the Act of 1881 the Post Office is entitled to a Royalty of 10 per cent. on the earnings of all wires excepting such as are "maintained or used solely for private use," and accordingly claimed the Royalty on all wires other than domestic or departmental telephones. On the other hand the National Telephone Company construe the clause to mean that all wires are private which do not touch the public exchange, and are available only for communications between two places, the contention of the Post Office being that no wire is private which is not confined to the interests of one firm, or one individual, and that wires running between two places of business do not come within the meaning of the words "maintained or used solely for private use." Mr. Justice Swinfen-Eady agrees with the Post Office on the ground that "if the words 'private use' merely meant not open to be used by the public, then any number of persons might be connected by a so-called private wire, and apparently by a private exchange, so long as none of the telephones were open to use by the public." The decision is so important as affecting the purchase of the company's assets in 1911, that it may be taken that the case will ultimately go to the Lords.

Consols and Trade.—The present low price of Consols has induced much loose comment. It is said, for example, that the national credit, as shown by the quotation, is lower than for many years past, and that it has fallen more relatively than that of other countries. Neither contention will bear examination. The only true criterion by which the comparative value of a security may be tested, is net yield, and the only way of ascertaining how British credit stands as compared with other nations, is to make the comparison upon the identical rate of interest. What then are the facts, taking the last twenty years? Assume that at the end of March, 1887, the reader had £100 in Consols, and that throughout the period under review the stock was upon a $2\frac{1}{2}$ per cent. basis in all the countries with which the comparison is made. The yield to him at the outset, that is to say in March, 1887, was £2 19s. 6d., in March, 1897, it was £2 5s. 3d., in March of the present year, £2 18s. 9d. In 1887, the year before the Goschen conversion, Consols were quoted—if allowance is made for the rate of interest—lower than now, the comparison being 84, with 85 3-16ths. Nor is it more correct to say that relatively, as compared with foreign Government securities, Consols are alarmingly low. On the contrary, Consols really give a smaller return than any Continental Government security. At the present quotation they yield £2 18s. 9d., and French Rentes come next with a yield of £3 3s. 8d., not a great difference, but still one on the right side. On the basis of a $2\frac{1}{2}$ per cent. security these Rentes would be quoted at $78\frac{1}{2}$ against the $85\frac{3}{16}$ of Consols. German Consols are third, giving a yield of £3 13s. 2d., and an equivalent quotation of $68\frac{1}{4}$; then Italian, £3 19s. 3d., the same yield as Russian bonds, the relative quotation of both being $63\frac{1}{8}$; Hungarian Gold Rente, again, would yield £4 6s., the equivalent quotation being $58\frac{1}{8}$. As the Chancellor of the Exchequer has reminded the House of Commons the price of Consols in 1885 was $94\frac{3}{8}$, or the equivalent to $78\frac{5}{8}$ for a $2\frac{1}{2}$ per cent. stock, and, as he also pointed out, "many of the causes contributing to the decline not only of British Government stocks, but also of most other high-class securities, which has taken place during the last ten years are international in their operation, and are independent of Government control." Foremost amongst them is the increased demand for money, and, as was pointed out in the Notes last week, this is lagely due to exceptional industrial and commercial activity at home and abroad. But this is not to say that the abnormal expenditure of recent years, a total addition to the National debt in a few years of roughly £200,000,000 sterling, has had nothing, or has not had much to do with the fall in Consols. The comparison with other countries is largely what it is because they too, in more less degree, have been spending largely above the average of earlier years.

CORRESPONDENCE.

FAMINE IN INDIA.

Sir Frederic S. P. Lely writes:—

I ask permission to make a short rejoinder to Sir W. Wedderburn's note on my famine paper. It was not, in Gujerat at least, "a great central fact that the famines were not famines of food, but of poverty." To a great extent they *were* famines of congenial food.

As pointed out in an unread portion of my paper (pp. 419-20), large numbers of those who broke down did so from being put on a new and less nutritious diet, and from nervous collapse. Very many died who could buy plenty of food without going on relief works, but that food was only Burma rice. Then, again, the "reserves" of the people consisted mainly of (1) cattle, (2) loans to neighbours, and (3) ornaments, only the last of which is liquid in time of famine. The other two only add to a man's burden. Sir W. Wedderburn's suggestion is, in effect, that the ryot should be encouraged not to invest his money in productive agricultural stock or in helping his neighbour, but in hoards of cash or grain. This would surely not be an economic advance. As for credit, nothing that Government could do would have induced any sane man, as a matter of business, to advance money to the crowds of day labourers, and the comparative few small cultivators who flocked for relief. As a matter of fact, the people showed wonderful resource and self-support. It is true that one-fourth of them were getting relief in July-August, 1900, but that was at the time of the highest strain, when things were at their worst, and when also we are said by the Commission to have been over-liberal. Throughout the year the number was very much less—probably never much over 15 per cent. I doubt if the proportion in Lancashire after every mill had been closed for a year, would be much less. The townspeople do not invest their surplus in the same way as the country people, and it is very remarkable that after two years of famine the octroi revenue, in Ahmedabad city, upon many luxuries, showed no diminution. In other parts of India, the local Governments have often congratulated themselves on the increasing staying power of the masses. These facts are known to all who have really studied the subject in the villages. Of course, much may still be done to strengthen the ryot against his day of trial, but the subject is too large to discuss in a casual note.

OBITUARY.

MARCELLIN BERTHELOT.—The sudden death of Monsieur Berthelot on the 18th inst., immediately after the death of his wife, has deprived the world of a great scientific genius, and the Society of Arts of one of the most eminent of its corresponding members.

A Bill was passed in Parliament for a public funeral at the expense of the State. The funeral of M. and Madame Berthelot took place at the Pantheon, on Monday, 25th inst., in the presence of the President of the Republic, and a vast multitude, consisting of the most eminent men of France.

Marcellin Pierre Eugene Berthelot, the distinguished chemist, philosopher, writer and statesman, was born in Paris, October 29, 1827. In 1851 his life-long friendship with Renan commenced. In 1854 he at once became famous in consequence of his doctoral thesis on the combination of glycerine with acids. The results of his researches in synthetic chemistry were published in 1860. In 1859 he had been chosen Professor of Organic Chemistry at the Ecole de Pharmacie, Paris, and six years later a Chair of Organic Chemistry was created for him at the Collège de France, which he occupied for the rest of his life. Here he devoted himself to the study of the relation between heat and chemical change, and his researches were described in his "Méchanique Chimique fondée sur la Thermo-Chimie," published in 1879; and followed in 1897 by two more volumes on Thermo-Chemistry. Besides these great works, M. Berthelot was a voluminous writer of papers, commencing in 1850, as may be seen from the Royal Society catalogue of scientific papers.

Mons. Berthelot was Minister of Public Instruction in the Goblet Cabinet in 1886-7, and Minister of Foreign Affairs in the Bourgeois Cabinet in 1895-6. From 1876 he was Inspector-General of Higher Education, a Life Senator in 1881, and in 1889 he succeeded Pasteur as Perpetual Secretary of the Academy of Sciences.

GENERAL NOTES.

THE PHILIPPINE ISLANDS.—Most of the foreign carrying trade of the Philippines remains in the hands of British shipping. The proportion to the whole has indeed fallen off, American and Spanish ships being the gainers, but of cargoes valued in the aggregate at £12,938,922, the British share was £8,775,465, as shown in the latest Consular report (Cd. 2682). It may be noted in this connection that the Act of Congress passed in April 1904, extending the United States coasting laws to these islands, known as the Frye Shipping Bill, has been postponed until 1909. One of the most striking features of Philippine trade for the year under review was the increasing trade with Australia, which country is now a formidable competitor of the United States in the market of raw materials. This result Mr. Consul-General Kenny attributes in no small measure to the energy of the commercial agents of the various Colonies who periodically visit the islands, and the enterprise of colonial exporters in sending representatives to the Philippines to bring their produce to the notice of the local buyers. The statistics of the flour trade furnish a good example of this. In 1903 the value of the flour imported from the United States was £161,302, in 1905 it had fallen to £104,573. On the other hand the flour imports from Australasia, taking the same period, rose from £237 to £48,404.

Journal of the Society of Arts.

No. 2,837. VOL. LV.

FRIDAY, APRIL 5, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, APRIL 10, 8 p.m. (Ordinary Meeting.) LOUIS FELBERMAN, "Arts and Industries in Hungary, in Ancient and Modern Days."

Further details of the Society's meetings will be found at the end of this number.

PROCEEDINGS OF THE SOCIETY.

APPLIED ART SECTION.

Tuesday evening, March 19; SIR LUKE FILDES, R.A., in the chair.

The paper read was—

OILS, VARNISHES, AND MEDIUMS USED IN THE PAINTING OF PICTURES.

BY A. P. LAURIE, M.A., D.SC.

(Principal of the Heriot-Watt College, Edinburgh.)

While in the past various mixtures were used by artists for painting, some of which are only obscurely understood, the necessary mediums for modern painting are, comparatively few.

The old painting in beeswax, which has proved remarkably durable, is no longer practised, and tempera painting with an egg medium is only used now and then. There are in this connection certain unsolved problems, such as the real nature of the medium used by Van Eyck and his immediate successors, which are of historical interest, but which I do not propose to discuss here. The medium in which the pigments are mixed must be closely related to the technique adopted by the painters of the day, and it is not at all probable that the medium used by Van Eyck, while united to his technique, would be of the slightest practical use to the modern painter. An artist's medium, then, has to serve more than one purpose. It must attach the pigment to the paper or canvas on which the picture is painted; it must facilitate the use of the pigment by the artist, and it must bring out all the qualities of translucency, and so on, which the pigment possesses. It should also, as far as possible, protect the pigment from change and injury, either mechanical or chemical. The simplest example of such a medium is the mixture of gum arabic and water, used in water-colour paintings. The gum arabic serves to attach the pigments to the paper, while the water gives the necessary facility to the pigment under the brush, and the qualities of the pigment are developed by thicker or thinner washes on the white paper background. Such a medium, however, does nothing to protect the pigments used from change, and has a limited though beautiful range of expression.

Painting in oil is practically the only other method used by the present day artist, and it is to painting in oil that this discussion will be devoted.

In selecting an oil as suitable for artists' purposes it is necessary to choose what is known as a "drying oil." If, for instance, pigments are ground in olive oil the surface would never dry and it is, therefore, useless for the purpose. There are certain vegetable oils which have this property of drying and which are, therefore, suitable for artists' purposes. I shall only refer to three here, linseed oil, poppy oil, and walnut oil. There is no need to trouble you with the chemical composition of these drying oils, but it is important that the nature of this drying process should be clearly understood. These oils do not dry in the ordinary sense of the term at all. They undergo a process of oxidation when exposed to the air, which converts them from a liquid condition

into a tough elastic solid, a solid which slowly undergoes further oxidation, becoming brittle, hard and resinous. It is then to this process of oxidation that their peculiar properties are due.

These oils are obtained from the seeds or nuts, and are present in those bodies as part of the reservoir of food supply for the young embryo of the future plant.

The oil from linseed is obtained by crushing, grinding and pressure, and in order to increase the yield the ground mass is heated as well as pressed, thus obtaining what is known as a hot pressed oil, which is subjected to various processes of refining and bleaching. Personally, while regarding such an oil as quite suitable for house painting, I doubt very much the wisdom of using it for artists' purposes. The hot pressing results in the presence of many impurities which are removed by the addition of sulphuric acid. The chemistry of the whole subject of painters' vehicles is so obscure that it is as well to cling to tradition where possible.

The linseed oil of the earlier centuries was cold pressed linseed, and was refined and bleached by the simple process of exposure to air and sunlight over water. These methods yield a beautiful oil, and should be adhered to for artists' purposes.

Poppy oil is obtained from the seeds of the opium poppy (*Papaver somniferum*) by crushing and pressing, or by other means of extraction, and is easily bleached. It is often used for grinding with whites or delicate blues. It dries more slowly than linseed oil, but has the advantage of being almost colourless.

Walnut oil is obtained from the common walnut (*Juglans regia*) by allowing the nuts to decompose partially and then pressing, and can be obtained almost colourless. It was largely used by the early Italian painters as a drying oil. There are other drying oils, but they are not of special interest to artists.

Having briefly discussed the three drying oils commonly used for artists' purposes, we now go on to consider some of the other vehicles and mediums. The pigment having been ground stiffly in oil is supplied to the artist, who may thus dilute or mix it further, and we shall proceed to consider the materials he may use.

In the first place he may merely add a little more of one of the oils already referred to. In case, however, that he wishes his picture to dry faster, he may use as a medium instead of raw oil, boiled or drying oil.

The property of the boiled oils depends upon the fact, that if, for instance, linseed oil is heated for some time with certain compounds, more usually either compounds of lead, such as lead oxides or lead acetates, or compounds of manganese such as manganese borate or resinate, it becomes partially oxidised, and if painted out on a surface will "dry" much more quickly.

Of the two methods of preparing drying oils described above, the use of manganese is I think preferable, and for this reason. A certain amount of the substances used dissolves in the oil, and consequently an oil prepared with lead dryers contains lead in solution, and is very easily darkened by impure air containing sulphur compounds such as sulphuretted hydrogen. It is, therefore, probably better to keep such oils out of modern pictures which are exposed to the impure air of cities.

Besides diluting with oil, the artist may prefer to dilute with a medium, which will evaporate and leave the layer of oil originally present behind. The mediums most commonly used for this purpose are either turpentine or petroleum. Turpentine, which is obtained by distilling the natural gums of the various pines, is a very suitable medium, as it not only evaporates easily, but also assists in the oxidation of the oil. It has been objected to turpentine that it does not evaporate clean, but always leaves a slight resinous residue behind. This is quite true, but the amount of this residue is very small, and, as far as my experience goes, it gets fairly hard in time, so that there is probably no objection to its use on this ground.

The petroleum oils have the advantage when properly rectified of evaporating quite clean and leaving no residue. I have said, when properly rectified. It is important before using such a medium to moisten a piece of blotting paper with it and expose it to the air for a short time. If properly rectified the petroleum evaporates completely, leaving no greasy stain behind.

Artists sometimes forget the real property of these mediums, and then complain afterwards that the pigment does not adhere properly to the surface of the picture. The amount of oil used for grinding different pigments varies very considerably. If the ground is slightly absorbent, and the pigment stiffly ground and diluted by the artist with petroleum, the oil in the pigment dissolves in the petroleum and passes freely into the absorbent ground, leaving the pigment when the petroleum has evapo-

rated without sufficient oil to bind it to the canvas. This may happen with one pigment but not with another, if in the original grinding more oil has been necessary to get a good consistency.

Having now dealt with the more important diluting mediums, we will consider next the question of varnishes. A very large variety of gums or resins are now available for varnish making, but the number used for artists' purposes is not great.

Varnishes may be conveniently grouped into two divisions, the one called spirit varnishes, and the other oil varnishes; the spirit varnishes are prepared from the softer and more soluble gums by dissolving them in some medium which will evaporate and leave a layer of pure resin behind, such as turpentine, alcohol, or petroleum. The varnish artists are most familiar with is prepared by dissolving gum mastic in turpentine. By evaporating, a layer of mastic is left behind. Shellac is usually dissolved in alcohol; and there are also petroleum varnishes in use.

Such spirit varnishes are brittle, weak, and easily dissolved or removed. They should, therefore, form no part of the body of a picture, but may be used to varnish a completed picture when thoroughly hard, mostly as a protective transparent coating which can be easily removed without injuring the painting beneath. Mastic varnish, for instance, can be removed by lightly rubbing with the tips of the fingers, the powder of the resin largely assisting. They are apt to bloom, in which case the bloom can be removed by a damp cloth, and some hold that they tend to crack the picture beneath; I have found no proof of this however.

We next come to the oil varnishes. Oil varnishes are or should be made of the harder gums which will not dissolve freely in turpentine or alcohol. To make an oil varnish the gum is fused and the hot oil added, and the whole heated until a drop placed to cool in a glass plate cools clear. It is then diluted with turps. To prevent too slow drying a drying oil may be used, or driers added, and heated with the varnish. While thus the fundamental process is simple, in practice great technical skill is required. But again, either manganese or lead driers can be used, and I advise, for artists' use, manganese driers; although the varnishes so prepared do not in my experience dry so quickly. The number of gums available, their means of supply, names, and properties, form a large and confusing subject, especially as no fixed and clear nomenclature has been arrived at.

For artists' purposes, a hard gum should be utilised, such as Zanzibar or Sierra Leone copal, or the hard kauri gum from New Zealand. Carefully selected pieces, light in colour, should then be carefully fused, and incorporated with pure linseed oil. Amber is a very hard gum of high melting point. The main trouble in using it is the difficulty of preventing it from getting too dark on fusing. This can be overcome, but in so far as I have been able to test its properties, it has no advantage over the kauri resins or copals. These, then, are the principal mediums in everyday use for painting oil pictures. I have excluded all special fancy mediums, as I do not know their composition. They may be quite harmless, but I object to them as a doctor objects to a patent medicine. An artist, if he is wise, will only use such mediums as are of known composition, and have stood the test of time and experience.

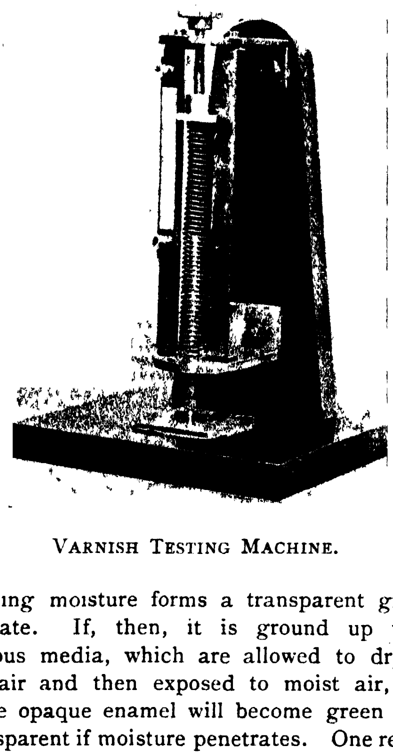
We shall next, then, proceed to consider various problems which arise in connection with these mediums, and which, I may frankly say, are far from being solved.

In the first place then how far do pigments act chemically on each other when mixed in an oil vehicle. To take a typical example. Will a mixture of white lead, which is so sensitive to sulphur compounds, turn black when mixed with vermilion (sulphide of mercury) or with cadmium yellow (sulphide of cadmium)? It is sometimes stated in the text-books that these pigments must not be mixed together, but all practical experience is against this view, and when we examine a pigment ground in oil under the microscope, and notice how the particles are each protected by a layer of oil, it is difficult to see how, unless the pigment is soluble in the oil, any action can take place. There is one well-known case when such action does take place, the turning brown of a green made with emerald green and cadmium yellow, but this I take it is due to emerald green dissolving slightly in the linseed oil. I once made an experiment which I think is of interest in this connection. I rubbed out some cadmium yellow ground in oil on a glass plate, allowed it to dry, and then coated it with a layer of linseed oil, allowed this to dry and then coated this with emerald green in oil. At the end of six months the combination had turned brown and a section under the microscope revealed the fact that the top layer of cadmium yellow had turned black. This must have been due to the

solution of the copper in the emerald green in the linseed oil and the slow diffusion of the copper salt molecules through the solid oil, with formation of black copper sulphide. It is evident then that pigments soluble in linseed oil will slowly diffuse through the solid oil and attack other pigments, but if they are insoluble no change seems to take place.

The next question is how far does the oil protect pigments from external influences, air, moisture, and injurious gases. I read many years ago a paper dealing with this subject at the Society of Arts.* Ignited sulphate of copper is a white opaque powder which is intensely hygroscopic, and in attracting moisture forms a transparent green hydrate. If, then, it is ground up with various media, which are allowed to dry in dry air and then exposed to moist air, the white opaque enamel will become green and transparent if moisture penetrates. One result was to show that while pure resins dissolved in turps formed moisture-tight surfaces, oils and oil varnishes were all quickly permeable.

FIG. 1.



VARNISH TESTING MACHINE.

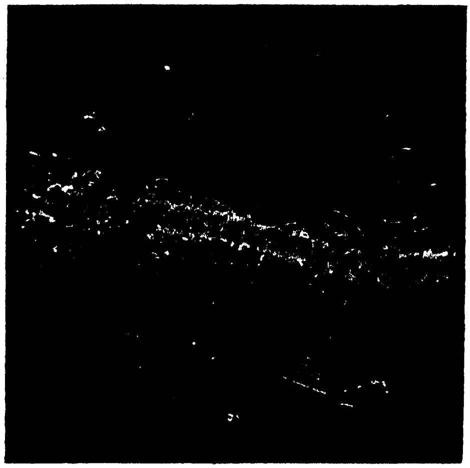
The same is true of other gases. Sulphuretted hydrogen quickly blackens white lead in oil through even an oil varnish, but if the white is ground in Canada Balsam and then varnished with Canada Balsam, the white is protected. Verdigris forms a permanent green in such a medium. It does not, however, stop though it checks the fading of crimson lake, showing that there is probably some decomposition of this colour in sunlight apart from air and moisture.

* *Journal*, vol. xxxix., 1891, p. 392.

It is evident, then, that while a freer range can be allowed to the oil colour than to the water colour palette, it is safer to select pigments which are permanent in themselves and not to trust to their protection by the oil from change.

The next question to be considered is the durability of the oil and varnish surfaces themselves. This has not received very much investigation as far as I am aware. I have been recently making experiments with a view to getting some comparative test for the combined toughness and hardness of a varnish. The method is to place the varnish painted out on a glass plate, and dry, under a blunt steel point, the pressure of which on the varnish can be increased by known amounts with a spiral spring.

FIG. 2.



MICROPHOTOGRAPH OF SCRATCH THROUGH CHEAP RESINOUS VARNISH, SHOWING CONCHOIDAL FRACTURE.

The varnish is then drawn under the point, and the pressure is increased until the varnish shows a clear definite scratch. Under this test the brittle spirit varnishes break down at a pressure of 100 grams on a steel point of 1 mm. radius, oil varnishes made from soft gums at from 300 to 500 grams, and oil varnishes made from hard gums, at from 900 to 1,200 grams. Moreover, the character of the scratch is very different. Varnishes with an excess of resin in them, and therefore made from soft, easily dissolved gums, give a

splintery scratch, while the tough oil varnishes, made from hard gums, give a tear. On exposure to weather during winter the varnishes are all soon reduced to a brittle surface which scratches at 100 grams, in summer however, they are improved by exposure. This clearly indicates that frost has probably much to do with this, and it is worthy of further investigation. It is easy by this machine to pick out a good varnish for the artist to use as a medium; and if this is done, no doubt the life of the picture, if kept under proper conditions, will be very much increased.

The next question to be considered is the occasional and capricious cracking of pictures. The explanation of this has, I confess, so far completely baffled me, but there are certain matters of interest in connection with it worth mentioning.

The great difficulty I have found in investigating this matter is due to the fact that I have been unable, under any condition, to produce cracking. The first experiment I tried was more than twelve years ago, when I painted out two, three, and four coats following each other quickly as soon as the last coat was sufficiently dry on the surface, of flake white (1) ground stiff with oil; (2) diluted with more oil; (3) diluted with copal varnish and (4) diluted with petroleum.

The same set of experiments were repeated with lead sulphate and zinc oxide paint, and with pure zinc oxide, thus making in all 48 different panels representing the different conditions. They are all perfect and show no signs of disintegration to-day. I have also tried painting on ordinary primed canvas with yellow ochre, and then as soon as it was sufficiently dry, laying over it strips of umber, a quick drying pigment—result, no cracks.

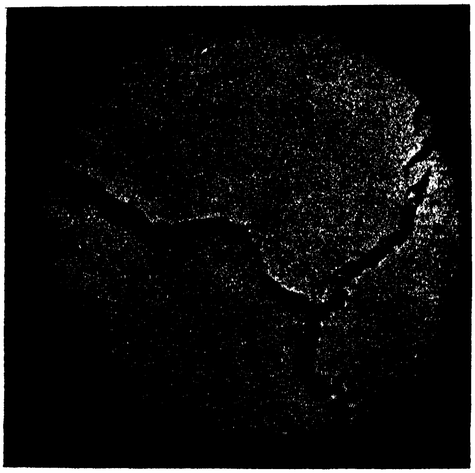
I have also tried the following combinations, undermost oil paint + mastic or pure mastic, second coat oil paint, third coat oil paint + mastic, umber + mastic, then yellow ochre, then mastic varnish, oil paint + olive oil, umber in oil on top, mastic on top, shellac varnish on top, and other similar combinations. All were hurried, no proper time for drying was allowed, and after twelve months they were free from cracks.

In no instance did any crack, with the exception of the shellac varnish, on the paint mixed with olive oil. I noticed, however, one curious result, the yellow ochre on the top of mastic varnish cracked while still wet owing to surface tension effects, but changed no more after it was dry.

These experiments then were all negative in their results, and certainly eliminate many of the causes to which cracking is supposed to be due.

I had the good fortune to be presented with two pictures which had cracked badly within a few months of painting. In the first picture mastic had been used as a medium, and the cracking was confined to the parts where thin liquid painting had been done and mastic probably freely used, as the surface here was hard and brittle. The canvas was of very poor quality, hardly closer in mesh than coarse muslin. A section through a crack when placed under the micro-

Fig. 3.



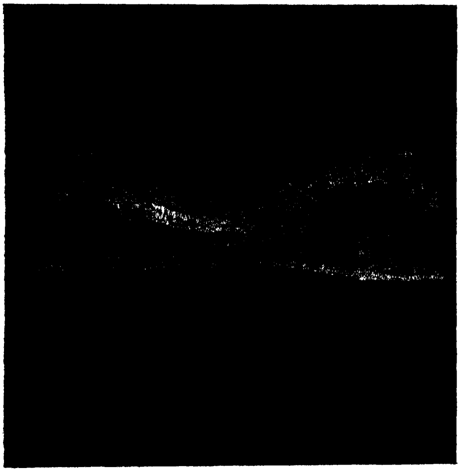
Microphotograph of Crack in Picture, Showing Cracked Upper Layer (Dark), and Uninjured Lower Layer (Light).

scope showed the crack to be merely through the upper painting, and to be a broad crack with straight edges perpendicular to the painting surface. The priming had not cracked, but seemed to be drawn out under the crack.

The second picture was painted on a closely-woven canvas which had been lightly sized and thinly primed by the artist with a mixture of pigments and linseed oil. The cracking was confined to the white masses of hard dry paint in the sky. A section showed that these cracks also formed broad cracks with perpendicular edges without injury to the under-coating of paint. The undercoating of paint did not, however, seem to be properly attached to the canvas, a layer of spongy disintegrated material apparently having formed in some way. This condition of things prevailed all

over the canvas and suggested that, owing to some disintegration between the canvas and the lower coats of paint, the coats of paint had been stretched, resulting in cracking of the upper coat where it was not elastic enough to yield. In order to get some light on the possible causes of cracking, I determined to measure the actual movements taking place in the canvas itself under different conditions. For this purpose I attached a strip of sized canvas by one end to a glass cylinder and weighted the other end so as to keep it taut over the cylinder. A platinum wire was firmly sewn to the canvas across and projecting out each side, and two little glass rods attached to the glass as indicators. The length of the canvas from the attached end to the platinum wire was 2 centimetres. By measuring the distance between the glass rod and the platinum wire it was possible to measure any expansions or contractions of the canvas itself.

FIG. 4.



MICROPHOTOGRAPH OF SECTION THROUGH CRACKED PICTURE, SHOWING CRACK THROUGH UPPER LAYER, AND UNINJURED LOWER LAYER OF PAINT.

By measuring at both ends and taking a mean any twisting of the canvas was eliminated. On first measuring, the average distance between the glass rod and the platinum wire was ·45 of a millimetre. The cylinder was then enclosed for twenty hours over strong sulphuric acid so as to dry the canvas thoroughly. The distance had now increased to ·55 mm., showing a contraction of the canvas on drying. It was now kept fo twenty hours in an atmosphere saturated with water vapour.

At the end of this time the readings showed a distance of ·28 mm., showing a total expansion from dry to moist air conditions of ·27 mm. On again replacing over strong sulphuric acid the distance increased to ·57 of a mm., showing a change in length of ·29 mm., or, taking the mean, of ·28 mm.

The canvas was now painted thickly with yellow ochre, and put back in the sulphuric acid and allowed to dry. After one day the distance between the points was ·54 mm., and after thirteen days when paint fairly dry it was ·577 mm., showing very slight changes in length during the drying of the paint. After twenty days the distance between points was

FIG. 5.

APPARATUS FOR MEASURING EXPANSION AND CONTRACTION OF CANVAS.

·57 mm. On now putting into saturated water vapour, the distance between the points became ·36 mm. instead of ·28 mm., showing a distinct and definite contraction on the original canvas.

A coat of umber was now laid on the ochre and allowed to dry in saturated air. In three days the umber was dry, and the distance between points was ·34 mm. On now putting back in dry air a further slight contraction took place, the distance between the points becoming ·66 mm.

A coat of yellow ochre was now put on and left over sulphuric acid; at the end of seven days the reading was ·73 mm., and at the end of a fortnight ·72.

These figures are a little difficult to follow, but leaving out small fluctuations they bring out the following facts very clearly.

In the first place, the total expansion, from dry to moist air, of the canvas tested, was ·28 mm. for 2 cent. length, or for 1 cent.—that

is 10 mm.—it was 1·4 per cent. In the second place, the drying of the thin layers of paint produced a total contraction of the canvas amounting to about ·16 mm. This contraction did not necessarily show itself while the paint was drying under fixed atmospheric conditions, but as soon as the canvas was set moving by change in atmospheric conditions, it asserted itself.

It is of interest to compare the magnitude of these movements with those required to produce a badly cracked picture.

The cracks in the picture mentioned above, varied in diameter from ·12 mm. to ·3 mm. roughly averaging ·2 mm., and measurements in different directions showed an average of about twelve cracks to 10 centimetres = ·24 mm. per centimetre, or about double the total expansion of the canvas, as tested.

After nine months, the strip of canvas painted as above described, was alternately put over sulphuric acid and over water some two or three times, expanding and contracting freely, but without cracking the paint. Another possible source of mischief had to be investigated and that was the freezing of a damp canvas. Two pictures were taken, one a canvas which had been primed twelve months before with sulphate of lead and zinc oxide, the other a portion of canvas previously described which had twelve monthe before been coated with yellow ochre and then when only just dry on the surface coated with umber. After 24 hours in saturated air they were kept some 4 or 5 hours in a freezing mixture. No cracks developed and sections showed all coats firmly adhering.

While, then, the result of the experiments has failed to reveal the cause of cracking, in the pictures examined, considerable negative evidence has been accumulated which should give us confidence in modern methods of painting. Cracking seems to be due to an expansion of the under layers (possibly due to the action of moisture and frost) which shows in cracks when the top coat is hard either from excess of pigment or from the presence of a medium like mastic.

On the other hand a sound canvas, properly sized and primed and painted with pure oil, and good oil varnishes, with the exclusion of fugitive pigments, seems to withstand very severe treatment without appreciable injury.

There is also very little evidence to confirm the usual statements about expanding surfaces when the paint is drying under normal conditions.

DISCUSSION.

The CHAIRMAN, in opening the discussion, thought all artists were under a deep obligation to the author, not only for the interesting paper he had given but for the thorough investigations he had carried out with regard to the properties of canvas, oils, and varnishes. After hearing the paper, he was very forcibly struck by the fact that there was a more hopeful outlook for artists in regard to the materials they used than he thought there would be before he attended the meeting. He had rather dreaded being present to hear the denunciations of the practices of artists, of which he was afraid many must admit they were guilty. He had imagined the author would state that the courses artists were now pursuing would end in the destruction of their efforts, but it was very comforting indeed to know that Dr. Laurie had tried his worst, and the quality of the work sseemed to be able to withstand even the very severe test he applied to it. It was very interesting indeed to notice the dissipation of certain traditions held by artists. For instance, with regard to cracking, he did not suppose there was any artist who was prepared to state what it was he had done which had caused the cracking of pictures. He had submitted some of his efforts to his friends, and they had without hesitation told him the reason of the cracking, and yet the author, with all his vast knowledge and experience admitted he did not know why pictures cracked. He thought the subject ought to be taken up by practical artists for the purpose of aiding investigators such as Dr. Laurie, so that artists would be able to perfect their methods. As it was, artists were extremely indebted to Dr Laurie for carrying out the work he had done on behalf of the profession. Artists were not particularly well up in the technicalities of chemistry, and he had no doubt Dr. Laurie would be able to elucidate any point which was not clear to any gentleman present. He thought it was obvious why the author had not referred to the firms which supplied artists with their materials. The present days were different from olden times, when the boy painter was apprenticed to his master, and learned the composition and use of different materials; but present day students did not seem to get very much information on the subject, not being taught by their masters the properties or the use of the materials. There was a good deal of "go as you please" among the professors and schools which he thought might well be corrected. He thought the master ought to explain to the student his method of painting, and what he should do and what avoid. There were broad principles which every student should know, and it would undoubtedly help him greatly to have a knowledge of his materials. He thought it was a well founded belief that the firms which provided artists with colours could be relied upon to produce the very best article, and they supplied what they stated they sold. As a rule that was the case in the very best firms. So that, taking it altogether, he felt more hopeful after hearing the paper than he did

before he came to the meeting. There was only one fear he had, namely, that if the author and other investigators succeeded in perfecting their processes, pictures painted in the future would not have cracks, and the colours would never change, so that modern painters would not be esteemed as old masters were, because many of the so-called merits of the old paintings appeared to depend a great deal upon the defects which the author had denounced.

Mr. ALFRED EAST, A.R.A., said he was somewhat disappointed at the paper, because he thought artists had not obtained much practical information from it, except a knowledge of the sources from which they could obtain their materials, which did not interest them very much. What artists desired to know was which materials, if used, would produce permanency when adapted to their use. The question of the cracking of pictures, however, did interest artists greatly; and in that connection he disagreed with Dr. Laurie's suggestion that the cracking was due to the canvas. It could not be due to the canvas, since pictures cracked when painted on wood panels. If the author asked one of his artist friends to take a number of new canvasses and paint out of doors, from early morning till sunset, he would find that none of them cracked; but if the artist took out old canvasses which had already been painted on and did the same thing, he would find those of the morning and evening would, after a short time, invariably crack, because the atmosphere would deposit a film of moisture upon the surface which prevented the adhesion of the second coat of paint upon the first. That was borne out by the habit of rubbing a potato on an old picture before it was re-painted, which invariably cracked in time. There must be a solvent upon the old paint which formed a tooth for it to grip in the contraction of drying. Artists had carried out such experiments for the past twenty years, and he thought they gave a clue to the real cause of cracking, which he believed was a fault entirely due to the artist and not the fault of the pigments or the vehicle. There was one other point to which he wished to refer, namely, that artists were in the hands of the people who prepared the pigments. The contrary was the case with regard to foods and drugs, because an Act of Parliament laid it down that the constituents must be known of any preparation sold under a particular name. That, unfortunately, did not apply to the composition of pigments. Another point was that artist's colourmen were in the habit of grinding all the pigments with the same oil, with the result that some dried fast and some slow. If a colour which dried slowly, such as madder, were ground with poppy oil, it stood to reason that if a fast drying colour was placed over it there must be underneath a contraction in the process of drying which would cause cracking. He particularly desired to hear the author's opinion on points of that kind. As a practical painter he thought it was desirable that painters should have a greater knowledge of chemistry, and that the chemists who dealt with vehicles and pigments should have a greater knowledge of painting. A combination of chemists and painters was required.

Professor J. M. THOMSON, F.R.S., stated that he had not attended the meeting for the purpose of discussing the paper, for the very good reason that the author had been asked to give the Society some information which he (Professor Thomson) could not give it in his paper on pigments last year. His duty in the previous year was to take the pigments and show the reactions which they had upon each other, but he was not, like the author, *au fait* with the question of varnishes and media. At the same time although he could not discuss the subject, he desired to point out to the meeting that Dr Laurie had opened up an enormous number of extremely interesting points for investigation. He was sorry that Mr. East had not been able to learn much about the practical application of the subject from the paper which had been given, but the question was in its very beginning. No one had ever examined the subject in the way Dr. Laurie had done; and he had rarely heard a difficult question containing as it did such a wide field so clearly and distinctly put before an audience. Although he could not criticise the paper, he congratulated the Society upon Dr. Laurie's paper, and his extremely brilliant and clear exposition.

Mr. WALTER F. REID cordially supported Professor Thomson's remarks as to the interesting nature of the experiments described by the author. He thought the micro-photographs, which had been shown, threw a good deal of light on the actual structure of the film of paint upon the canvas. Personally he did not think the canvas was at fault, not only because cracks were found on paintings executed on copper and wood, but also, as the author had stated, the cracks were found on one set of paintings and not upon others, although they were painted on similar canvas. He was rather disappointed that the author at the commencement of his paper dismissed, in such a very short manner, the old mediums that were used, and which had lasted for such a very long time. He was sorry beeswax was dismissed in such a curt manner, because he believed it was a medium which might be adapted. Artists now had absolutely permanent foundations, there being forms of asbestos in sheets which were completely mineralised, and which would give a better foundation than canvas, wood or copper. If modern artists would only utilise the materials which ancient artists used, and which it was known were durable, pictures would be painted which would last. Very clear descriptions existed of how the materials were prepared, written by Vitruvius, and other writers. Ordinary beeswax was not used, but what was called Punic wax, which was ordinary beeswax kneaded in sea water, exposed for a long time to the atmosphere, and purified by a special

process described. Another important point was that it had not the action on many pigments which linseed oil had. It was well known that linseed oil first became elastic and tough. He had made a number of experiments on the strength of the material, and had found that a film of it would stand its own weight in a length of about 10 feet. That was its tensile strength when it was new; in about a month's time it was halved, and it became rotten very quickly indeed. The author stated that, in his opinion, the elastic substance became ultimately converted into a resinous brittle substance. He desired to ask Dr. Laurie whether he had ever carried out experiments in that direction, because as a fact the reverse was the case. If the elastic tough substance which was the first product of the oxidation of linseed oil was exposed to the air under ordinary conditions in a room, a syrup was obtained. He showed at the Society in 1891, a sample of the very best quality of linseed oil which had been exposed to the air since 1878, and had liquified; he looked at it on the previous day and found that it was even more liquid than it was then. It kept on absorbing oxygen from the atmosphere. He had made an experiment on a thousand tons of linseed oil, and found that the oxidation forming the gelatinous or elastic substance caused an increase of weight of about 12 per cent. If such substances as bitumen, umber, especially burnt umber and some of the oxides of iron were used, cracking would undoubtedly be obtained in a year or two, especially if used on a foundation of linseed oil paint and not direct on to glass or some firm substance, because the linseed oil paint underneath softened; and when the super-oxidised oil in connection with bitumen became soft then the tendency was for the whole thing to crack up and contract. The contraction was enormous in the case of bitumen. He had a portrait at home painted by Sir Thomas Lawrence in which the cracks were nearly a quarter of an inch wide. Some of Lawrence's pictures in the National Gallery also showed great cracks in the dark colours, but they had been repaired and did not show up so well. Such facts he thought were incontrovertible; anyone could make the experiment and ascertain the results for himself; and he thought they threw considerable light on the real cause of cracking. He would not say that canvas was a desirable thing to paint on because it was perishable. He had seen canvas which contained a good deal of jute, which was one of the most perishable fibres, but that was due to the dealers. He thought the dealers were not quite so open with the wares that they sold to artists as they might be. The secresy observed by them had been handed down from the middle ages, but he was inclined to think that a colour manufacturer who would invite his clients to go into his factory and watch the processes would do a very good business indeed, and that his competitors would suffer. Many manufacturers pretended to have secrets which they really did not possess, because the foundation of the manufacture of pigments and varnishes was thoroughly well known. The method of purifying linseed oil with water was a very good one as far as it went, but it was a little fallacious, because no matter how long the oxidation went on a deposit was obtained at the bottom of the water, the reason being that the oxidised linseed oil which formed was heavier than water, consequently whenever unoxidised oil was exposed over water the oxidised oil fell down to the bottom of the water and a sediment was obtained. It was not an impurity in the oil at all, it was the oil itself. Such treatment did get out all the corruptible snbstances in the oil in the first instance, and that was an advantage. The material that Van Eyck used was, he thought, very well known, having been left on record. There were Italians who claimed that Antonelli di Messina invented painting with linseed oil, and in the Corsini library at Rome some interesting particulars were given about the materials used. Clearly linseed oil was referred to, but nut oil was mentioned earlier than linseed oil in the Italian record, and it was rather doubtful whether the nut oil was walnut oil. The question the author had raised with regard to manganese and lead was one of importance. It was quite true that lead darkened with sulphuretted hydrogen, but it must not be forgotten that manganese itself darkened through oxidation. Although the experiment the author showed was very striking, the proportion of manganese must be kept as low as possible in order that the oil might not discolour itself afterwards. He thought the author would acknowledge that the experiment he showed was made with a much larger proportion of lead than there would have been in oil boiled with lead. With regard to turpentine, unless it was analysed at the time it was bought it was impossible to know what was being sold. The whole trade was being disorganised, because certain manufacturers bought up all the turpentine that contained certain chemical substances for use in a new synthetical process. It was a most difficult matter to buy two lots of turpentine on the market of the same quality. Petroleum was very stable and useful, but the difficulty connected with it was that it was not such a good solvent as turpentine. He desired to express a word of admiration for the interesting little pieces of apparatus exhibited by Dr. Laurie, which were of very great use in investigations. He hoped the author would continue his researches, and read a further paper on some future occasion. The analysis by the author showed that the amber varnish could not have been a true sample, although probably it had been sold as such. He knew from many years' experience that a good amber varnish was the best in the world, the reason probably being that amber varnish contained the oldest fossil resin. At the St. Louis Exhibition there was a splendid exhibit of amber from Prussia. The Prussian Government had taken over the whole amber industry. They produced from the waste what they called amber colo-

phony, which they found was very much better for making varnish. He had seen some of the best varnishes made from that substance, which was easily soluble in oils. He desired also to refer to the question of movements in the canvas. He thought it would be found in any painting that had cracked that it colud not be due to any shrinking of the whole picture, because unless some buckling of the picture took place the surface remained the same. It could only be a relative movement of parts, and as that did not take place in an ordinary good picture it would hardly be the only reason for the cracking in an indifferent one. If only one firm of artists' colourmen would take artists more into their confidence, he believed the artists would flock to that particular firm and buy their materials there.

The CHAIRMAN, in proposing a hearty vote of thanks to the author for his intensely interesting and instructive paper, said from his own point of view as an artist, he was deeply indebted to Dr. Laurie for the way he had started the subject. He did not presume for a moment that the author meant his dictum should be taken without any question at all; he had merely brought the question forward in the experimental stage in order to try and discover the best means of correcting any defects that existed. He thought no greater compliment could be paid to the author than the remarks that Mr. East had made. Mr. Laurie's address was not intended to be final; it was intended to provoke discussion, so that the ideal Mr. East desired might come about, namely, to get a combination of the artist and the chemist. He agreed with Mr. Reid's expression of admiration of the experiments made by Dr. Laurie, and particularly with regard to the instruments he had designed, which he thought were admirably conceived for the object he had in view. It was extremely difficult in such matters to put forward any proof of a particular assertion, and an artist wanted a great deal of proof before he accepted any particular statement. He had been quite charmed with the micro-photographs, which demonstrated the truth of the assertions Dr. Laurie had made.

The resolution of thanks was then put, and carried unanimously.

Dr. LAURIE, in reply, stated he desired to correct one false impression which he seemed to have made, namely, he did not mean to imply that he thought the cracking of the picture was due to the movement of the canvas. He merely stated that he thought it right to begin experimenting at the groundwork, and find out whether the canvas did move and what movement it was capable of. That was obviously one point which must be investigated, because it was necessary to go step by step before any definite conclusion could be arrived at. Mr. East made the very interesting suggestion that the cracking was probably due to moisture between the layers of the pigment, the canvas being damp when the second painting was put on. That might be so; and he promised Mr. East he would make the experiment to see whether he could succeed in getting cracking in that way. As he had stated in his paper, it had been his misfortune not to succeed in getting cracking. Mr. East also suggested the painting of a quick-drying pigment over a slow-drying pigment. He actually put on some olive oil in the under coat and painted umber on the top, and it did not crack. It might produce cracking in certain conditions, but not necessarily. Mr. East also complained that he had not received much enlightenment, and that he wanted more practical information than he had obtained. He (Dr. Laurie) quite agreed with him. He stated at the beginning of his paper that he was afraid he would not be able to give any very final dictum on the point because the matters were not at all cleared up. The result of his experiments had been to show that the usual explanations did not account for the facts, but that they still had to be discovered, and would, he hoped, open up possibilities of investigation which he had not been prepared to give that evening. He quite agreed with Mr. East that it would have been very much nicer if he had been able to tell artists that if they did so and so certain results would follow. He could not follow Mr. Reid through all his interesting remarks. He was quite aware of the experiment he referred to, in which oxidised linseed oil had liquified; but it was impossible to reconcile that experiment with what happened in an ordinary picture, where linseed oil did not liquify, and where it was not mixed with a basic substance at all. The worst case of cracking that he had shown on the screen was on a canvas where ordinary white lead had been painted in the sky, and that had cracked. That was a case of a basic pigment in which cracking had taken place. In the course of his experiments he tried pigments of umber and ochres, which were apt to cause cracking, but they would not crack. The experimental evidence was not at all conclusive. Mr. Reid's suggestions were very ingenious, but, as far as his own experience went, they were not conclusive any more than the remarks Mr. East made. The matter required further investigation. With reference to the remarks that had been made about amber varnish, he simply took certain trade samples, with the results he had described. He quite agreed with Mr. Reid, that probably neither of the samples contained any amber at all, although they were sold as amber varnishes. He would be exceedingly obliged if Mr. Reid would send him a sample of the amber varnish made by the Prussian Government, in order that he might test it with his machine against the copal varnish. He did not think it was possible to go into the question of how Van Eyck painted his pictures. His own opinion was that

they were not painted with oils. Probably some present knew that the evidence which was given in the Italian records had been disputed, it being stated that the person who said he was taught by Van Eyck was born many years after Van Eyck died. He could not agree with anybody who said that Van Eyck's pictures were painted with ordinary oil pigments, because he did not think the result could be obtained with them. For one thing, he did not understand the condition of the verdigris; and he believed he was supported in his opinion by a great many other chemists. The two oils used in the experiment he conducted at the meeting, were bought in the open market. He bought a sample of artists' drying oils in an artist colourman's shop, and another sample in another shop. One turned out to be lead, and the other manganese, and in making the experiment he did not add any lead to the article as it was sold. The difficulty with regard to the liquifying of oil was that it did not seem to happen on pictures, and that he did not think the basic bodies would account for it. The tendency of linseed oil was rather to resinify than to turn into a liquified form, but he had not any clear evidence of its doing one or the other. If any artist possessed old cracked pictures which he no longer regarded as of any value, he (Dr. Laurie) would be extremely obliged to receive them, so that he might cut them up into sections, and put them under the microscope.

THE BRITISH INDIAN COMMERCIAL MISSION TO SOUTH-EASTERN PERSIA.

II.

Statistics.

Trustworthy statistics are difficult to obtain, except in the Customs Reports for recent years, and in this respect it must be admitted that there is a great improvement in the figures of the Belgium Administration of the Persian Customs. They declare the total trade of Persia in 1902-03 to have been over £8,000,000, consisting of over £5,000,000 imports and £3,000,000 exports. Other reliable information makes it fairly evident that these figures rather underestimate matters, and that the total imports and exports averaged £9,000,000 annually. Of this trade £4,000,000 was, roughly, with Russia, £3,000,000 with the British Empire, and £2,000,000 with other countries.

The official statistics for 1903-04, are less satisfactory for us though they show a considerable increase in the total trade of Persia, which amounted to £10,661,695, imports being £6,415,609, and exports £4,246,086. Russian trade shows a very substantial increase, while British on the other hand shows a falling off, and amounts to only £2,490,000. Both Russia and Britain preponderate enormously. When it is considered that Russia trades in particular with the northern parts of Persia, which are undoubtedly richer and more prosperous than the south, that Persia is her next-door neighbour, that the trade has not only been assiduously nourished, but "spoon-fed," and that Englishmen have to work against a tariff which has been especially planned to kill our trade and foster that of Russia, the figures are not so discouraging. Improvement could be made by an expansion of existing trade, the opening out of new connections in unexploited parts of Persia, and beating Russia by her own methods, if necessary, *e g.*, by special rates for freight, subsidies and rebates. It must be borne in mind that the proportion of our trade which would need thus bolstering would be very small in proportion to our entire trade, whereas with Russia the reverse is the case.

Fluctuations of Trade.

In Persia, as in India, the yearly fluctuations of trade depend chiefly on meteorological conditions and on the consequent economic position of the people. In 1900 and 1901 the winter rains, on which the life of Persia depends, practically failed. There was a consequent and immediate shrinkage of the already too scanty cultivation all through Southern Persia, which region has not yet recovered from the effects of the drought and a corresponding shrinkage in Persian trade. To draw any valuable conclusions, therefore, the figures and meteorological facts must be studied over extended periods of time.

Judging from reliable critical estimates and information it is evident that the trade of Persia, alike in imports and exports, has increased within the last few years by from 15 to 20 per cent. This increase, has, however, been for the most part in the north of the country and in Russo-Persian trade.

Sugar comprises one-half of the Russian exports to Persia. The consumption of sugar in Persia is enormous, and she produces none herself. Beet-root cultivation has been tried, but with no success to speak of. Owing, however, to the fact that over a great portion of Persia Russian sugar is unsaleable, Russia contemplates claiming certain concessions for the growing of beet-root and the manufacture of sugar in Persia. If, however, through rates can be secured and a careful study made of national taste, Indian sugar, both crystal and loaf, should oust the French, Egyptian, Austrian, and Belgian products, which flood the southern half of Persia. Indian sugar has greater sweetening power and purity than the above-named manufactures. In tea, the trade could be largely developed by careful study, and by shipping a moderately-priced and light-liquored article, for the latter is that to which Persian taste has been educated. In yarns and twists, India holds a very firm position, but this might be improved still more if she could manufacture some finer grades; similarly, India might be able to get in more cotton goods and prints than she does now, and secure almost a monopoly in woollens.

The shipping companies and railways must do their

share by granting special and reduced through rates, a thing they can well afford for goods intended for Bander Abbas and Bushire, as is now done for goods for carriage over the Quetta-Nushki route to Seistan. The Persian Government should be exhorted to bring about an improvement in the Port of Bander Abbas, and construct a good caravan road to Bam, over which wheeled traffic would ply, or to grant a concession, as in the case of the Bakhtiari road (Lynch road) to some English firm. A little rational irrigation in the plains of Bam-Narmashir, Jiruft and Rudbar, coupled with the foregoing, would mean a golden harvest for the Shah.

Russia's influence in the north is all-powerful and her proximity enables her to exert pressure in Teheran. Her consuls in some cases virtually rule Persian provinces, and neither the Court nor the people find cause for objection, for are there not the Cossacks over the border, and the railway tracks leading up to Moscow and St. Petersburg, with the immediate prospect of motor cars running direct to Teheran, for which a concession has been granted to Russia. In the South, Russian consulates and agencies are being opened. Many of the Persian Customs officers keep Russian officials and merchants *au fait* with Persian trade and act as agents for the spread of Russian goods. The Belgians, their supposed neutrality notwithstanding, are or were naturally more in sympathy with Russia than with the British, by whom they are regarded with some suspicion.

Fortunately the Indian Government are alive to the importance of trade with the countries beyond the Indian frontier.

As to Persia's exports, three-quarters or more of these are raw produce, vegetable and animal, the main part going to Russia. The vegetable products, which comprise dried fruits, raw cotton, opium, rice, gums and dyeing materials, are capable of great improvement; the animal products consist mainly of silk, cocoons, skins, pelts, intestines, wool, and pearls. The remaining fourth part comprise chiefly carpets, with a very small quantity of leather goods. The best of the Persian carpets are made in Kerman and are exported to India, the United Kingdom, Turkey, Europe generally, and America; cotton, silk, and woollen tissues go to India, Afghanistan, and Turkey; and leather goods to Russian Turkistan. Amongst articles which might be more largely exported to India are wool, cotton, pistachios, almonds, raisins, gum tragacanth, and various dyeing materials.

As to mills or factories it would be hopeless for any Indian or English manufacturer to think of establishing works in Persia at present, the chief difficulty being the stringent rules under which it is permitted to foreigners to own houses or land in Persia, and after that the great cost of transporting machinery inland. A good road, though fit for wheeled traffic from Bam to Kerman, would help to change matters very soon.

TRADE METHODS.

Trade methods vary in Persia, those in Central Persia being somewhat different from those obtaining in Kerman and the South-Eastern region. Sales in Yezd and Ispahan are made when wholesale, on the basis of a fixed price with long credits which operate in the nature of a discount, which varies in proportion to the fluctuation in market price.

The great drawback to trade, apart from the state of the country and communications, is the absence or rather the primitive state of commercial law in Persia. For the term law may be read custom, assisted by the Koran and complicated by bribery and corruption. The payment of accepted bills cannot be enforced, and bankruptcies, many of them fraudulent, are common amongst the smaller fry of traders who, on very slight provocation, take refuge in the sanctuaries or refuges, called *Basts*, which abound in the country. Such bankruptcies are more rare among the bigger merchants, who are made to pay very heavily for the privilege of taking Bast by the mullahs in charge, and Bast is at best little better than prison.

BANKS AND BANKING.

There are two European banks in Persia. The first is the Imperial Bank of Persia, an English concern; the other is Banque d'Escompte et des Prêts, which is connected with the Russian Government, managed by a Russian Government official, and is practically a department of the Russian Government. The former has about ten branches and ought to have one at Bam, as well as one at Bander Abbas, which would be beneficial both to the Imperial bank and to British trade.

Besides the two banks there are many money-lenders, viz., Shikarpur Hindus, Armenians, and Mohammedan Shroffs. Although the Koran forbids Mohammedans to lend money on interest, they find a way out of the difficulty by charging, in lieu of interest, a premium as consideration for the favour of the loan. The mortgaging of land is common, but the holders of the deeds are as a rule very glad to assist their debtors to resume possession, especially when these debtors are the heirs of a dead mortgager. Mohammedans think that property acquired under such circumstances carries with it a specially deep curse.

Banking as yet has not taken a firm foothold in Persia, the natives being bewildered by calculation of rates of exchange, of discounts and interest. Content to eat, sleep, and be merry after their own fashion, as long as they can do so without feeling the pinch of want, they are glad to let others do the banking. Among such people, centuries behind European business habits, banking must be a difficult affair and of slow growth.

Persia is a silver country and its monetary unit is the kran, a silver coin worth now about fourpence. Recently a nickel coinage consisting of $\frac{1}{20}$th and $\frac{2}{20}$ths of a kran has been minted in Belgium for the Shah and all copper coins withdrawn. The Persian mint

issues at various times, gold coins of various values from 5 krans up to 10 tomans (1 toman is equivalent to 10 krans or 200 shahis). These coins are, however, not legal tenders. The Imperial Bank issues notes of tomans 1, 2, 3, 5, 10, 20, 50, 100, &c., and these are legal tender. This bank, which is the only institution in Persia with a legal right to issue notes, has a circulation exceeding in value £500,000 sterling. But owing to various reasons of which the chief is the extreme costliness, slowness and insecurity of transport over Persian roads, and for other reasons the bank has now been compelled to limit the encashments of notes to their own circles, except, of course, for small sums, or, at a very heavy discount, to travellers.

THE ROUMANIAN TOBACCO INDUSTRY.

The tobacco monopoly in Roumania was created in 1864, when the State reserved the right of sale of foreign and native tobaccos of all qualities and forms, and of cultivation. A special authorisation was necessary for its cultivation by private individuals, and so strong was the opposition that the law was repealed in 1867. In 1868 the cultivation became free, except for a certain tax. The trade in manufactured tobacco and the exportation of native tobacco were free. This lasted until 1872, when the State once more reserved the right of cultivating, manufacturing, and selling tobacco throughout the country. The monopoly was given to a company for fifteen years, divided into periods of five years each, with an increase of 20 per cent. on the payments of the company to the State for each period. According to the American Consul-General at Bucharest, from 1872 to 1877, the company paid to the State £324,000 a year for the monopoly. It decreased the amount of land under cultivation, and limited it to certain districts. The average was not more than 6,750 acres, producing about 3,750 tons of tobacco. During the first two years the company lost £160,000, but in 1875 it made £40,000, and in 1876 only £5,720. There were many complaints from the consumers about the inferior quality and the cost of the tobacco. In 1878, the company gave up its contract, and sold out to the State for £145,500. In 1880, the present administration was organised under a new law. Each year, in October, the administration gives notice by advertising, of the districts in which the cultivation of tobacco for the next year will be allowed, the area which may be cultivated, and the price which will be paid for each quality. Any person wishing to grow tobacco applies to the mayor of his district and the administration signs a contract with him if the conditions are satisfactory. The amount of land to be cultivated is fixed and must be sown with seed which the administration supplies grown in each region. Any variety not allowed is destroyed, and if any is found later the cultivator is fined and his contract annulled. The cultivation of tobacco commences in the month of March, when the seed is sown in the open ground and carefully covered during cold weather. When the plants have five or six leaves they are replanted in rows 20 to 30 inches apart, and 8 to 16 inches between plants. When the leaves begin to get dry and yellow the picking commences from the bottom up. As the best leaves are those which get yellow the slowest, delay is encouraged by cutting and pinching certain parts of the plant. The leaves must be gathered in dry weather and in the evening. They are taken to a dry place and pressed with their tips free, for from twelve to twenty-four hours, in which time they commence their first fermentation. Every day the agents of the administration check the number of bundles hung up. Along with the gathering and drying, the agents of the administration weigh the crop in the presence of the mayor of the district, and receipts are exchanged. Every bundle missing is estimated at five shillings, which is deducted later from the payment to the cultivator. Ten per cent. loss on the first weight is allowed at the time of delivery to the administration in November and December, and for every pound less than that a fine of one shilling and eightpence is exacted. Delivery is made in the presence the cultivators, where each bale is opened and weighed, after a careful examination and classification of the tobacco. The amount to be paid to the cultivator is finally settled. Three varieties of tobacco are grown in Roumania, two of which, the Persicean and Iaka, were brought from Macedonia, and the third, Samsun, from Asia Minor. The seed for the Iaka is imported each year from Macedonia. Experiments are being carried on with tobacco from Hungary and Herzegovina with fairly good results. There are experiment stations in various parts of the country with a view to improving the quality of the tobacco grown and to introducing new varieties. The cultivation of tobacco is also helped by the administration in a variety of ways, as by the establishment of funds for the assistance of the cultivators by lending sums of money varying from £8 to £24 for the construction of drying sheds and store rooms, by annual prizes of cattle, machinery, fruit trees, money, &c., and by making good any losses by hail or fire. Cultivators are also able to obtain the materials and implements necessary on the instalment plan. During the last year the administration has started an experiment station at Bucharest, with a library, laboratory, and trial fields. A bulletin is published every month giving the results of the experiments made and articles on the cultivation. The dried tobacco delivered by the cultivators has to be fermented in order to acquire the aroma and special properties for smoking. This takes place in the spring of the year following the gathering in separate sheds. The best qualites of tobacco receive particular attention, while the inferior sorts are fermented in masses. During the process the temperature goes up to about 90

degrees or 100 degrees, gas being created, the disappearance of which indicates the end of the operation. The leaves are then packed in bundles weighing some 65 lbs., and sent to the central depot in Bucharest, where they are kept until sent to the manufactories. There are six fermentation depots. The total amount of the raw tobacco used in Roumania is 4,250 tons, valued at £224,000, of which 625 tons, costing from £80,000 to £120,000, is imported. Some 80 per cent. of the latter comes from Macedonia and Asia Minor, and 125 tons from America, Sumatra, Java, Japan, and Hungary. The purchases are made by open bidding from samples presented by the sellers. When the tobacco from the fermentation depots arrive at the factories, it s sorted with care and the different qualities are mixed in the proper proportions. In 1905-6 the output was 35,957 tons of smoking tobacco, 264,000,000 cigarettes, 11,625,000 cigars, 207 tons of snuff, and 559 tons of tobacco juice for insecticides. The total value was £1,650,000. The net revenue of the monopoly for the last year for which the statistics have been published was £1,136,000.

THE PROGRESS OF SOUTHERN ITALY.

The year 1906 witnessed three important events in the commercial history of Italy. It saw a surplus of 40,000,000 lire (£1,600,000) in the Italian Treasury; the conversion of the 5 per cent. Rente was successfully carried out; and the eruption of Vesuvius, which had the effect of swelling the tide of emigration to the extent of depopulation in some cases, and caused the agricultural population of the Central Provinces to emigrate to the South in search of work. Successive Governments, ever since the unification of Italy, have had to reckon with serious deficits, but not only was there a substantial surplus last year, there is every probability of its being larger this year. The conversion of the Rente into 3¾ per cent. for five years, to be subsequently reduced to 3½ per cent., has effected present reduction in the payment of interest on the debt (£324,000,000) of £800,000 per annum, and five years hence the reduction will be £1,600,000. There was much discussion after the eruption of Vesuvius as to the desirability or otherwise of re-building the destroyed towns. It was thought by many that it would be better to select a site in the plain further away from the mountain, and with greater railway facilities. But the population insisted upon the actual re-building of their old houses, and the close of 1906 saw a very large portion of the inhabitants installed again on the old sites, so that it is safe to predict that in the course of a year from the date of what appeared to be their absolute destruction both Ottajaro and San Giuseppe will rise again from their ashes.

In his report upon the trade of Southern Italy just issued (Cd. 3283) Mr. Consul-General Néville-Rolfe directs attention to the great development of the Port of Naples (which now holds the third place in Italy as far as merchandise is concerned), whose tonnage has risen from 893,216 tons in 1895 to 1,292,201 tons in 1905. The increase in shipping in the same period has been still more remarkable, having risen from 3,523,991 tons in 1896 to 10,000,000 tons in 1905, an increase due to the mail and passenger traffic, which has raised it to the first place among Italian ports, while taking passengers and goods together, it now holds the second place, being only surpassed by Genoa. It is believed that the maritime importance of Naples must continue to develop, and the Italian Government has voted £564,000 for the further development of the port and quays. A new steam basin is also to be made to the east of the existing harbour, for which £500,000 has been voted in addition, and in order to render this basin a safe anchorage, a large breakwater will have to be constructed at once. The new Custom House for passengers, which seemed so handsome and vast in comparison with its small and shabby predecessor, is now quite insufficient for the purpose of clearing the baggage of the large number of passengers which arrive by the great liners of to-day, and it will be necessary to make a new hall.

The large trade done in silk from Italy to Egypt has become an important factor in Italian trade. Nowadays, Egyptians earn money easily, and they spend it freely. Formerly, nearly all their silk came from France. Now the French manufacturers are being hard pressed by the Italians, the Egyptians preferring the greater lightness of Italian goods, and the lower price. A new Italian product, called the "silk zephyr," which was first exported to Alexandria four years ago, has proved a striking commercial success. It is a light fabric, made in various designs, traversed with a light cotton thread which is sufficient to give it the required consistency for dress fabrics, and its cost is from 1s. to 1s. 10d. per metre f.o.b. at Alexandria. The width is 28 inches, the exact width of the French being 20 inches, and it is the additional width, and the showy stripes of the Italian product which appeal especially to the Oriental mind. Italian trade with Crete, too, is growing rapidly, the Italians holding an important place in the cotton goods market in that island. There is a strong export of textiles from Italy to Crete. The trade is of very recent growth, having been hampered for want of direct communication, now improved. A direct line will, in all probability, be shortly established. The success of Italian goods in Crete is only a part of her rising trade with Syria and the Levant generally, where Italy's goods are annually taking firmer hold.

The great increase, in recent years, of tobacco cultivation in Italy has led the Finance Minister to consider a scheme whereby the country should be able to grow all the tobacco necessary to furnish this important Government monopoly. At present, large quantities are imported from America, but as the Kentucky variety is found to do remarkably well in Italy, experts have been sent to Sardinia, Sicily, and

to various places near Rome and Casentano, to instruct the peasants in the cultivation of the plant, and to induce them to allot a portion of their ground to growing it. The cultivation of india rubber has also begun. The india rubber tree grows freely in gardens as an ornamental shrub in Southern Italy, and steps are being taken to make an industrial business of it. It is a plant which will do with dry weather, but flourishes more with irrigation, and as most of the cultivated land of Italy is irrigated it should do well if the climate is warm enough.

Perhaps in no country has there been a more remarkable development of the automobile industry. In 1903 there was only one firm of automobile manufacturers in Italy, and its capital was only £120,000. In 1904 seven more firms entered the list. In 1905 the total number had risen to 51, and the capital now employed in the industry amounts to an enormous sum. Italian motors, both on land and water, have proved themselves admirably adapted both for speed and resistance. The principle hitherto adapted only for sport and light vehicles is extending to commercial uses with great rapidity, and agriculturists have not been behindhand in adopting it to the purposes of their industry.

ADMIRALTY CHARTS.

The following is the official list of charts issued by the Hydrographic Department of the Admiralty in January :—

New Charts.—3643—Ports in the Shetland islands: —Balta harbour. 3600—Japan: achorages in Yezo island:—Yesashi anchorage; Abashari anchorage; Nemoro anchorage.

New Plans and Plans added.—Africa, north coast; Bizerta lakes. Plan added:—Lake Bizerta.

Charts that have received additions or corrections too large to be conveniently inserted by hand, and in most cases other than those referred to in the Admiand telegraph chart. 2151—River Thames:—Broadness to Mucking light. 2298—Gulf of Bothnia, sheet III.:—Nystad light to Stor fiord. 2300—Gulf of Bothnia, sheet V.:—Stiernö point to Fiärderäg. 1073—France, north coast:—Dieppe. 909—North American lakes:—Mildrum point to St. Joseph island. 373—Plans in the gulf of Mexico. 2458—Alaska:—Port Simpson to Cross sound. 3569—Alaska:—Port Valdez. 643—Africa, south coast:—Port Natal. 1000—Siam:—Pulo Condore group. 1342—Cochin China:—Fan rang bay to Tonking gulf. 1602—China, east coast:—Approaches to the Yang-tse-kiang. 3585—China, east coast:—Approaches to the Woosung river. 3274—Yang-tse-kiang:—Tung ting lake and Siang river. 1256—China, north coast:—Gulfs of Pe chili and Liau tung. 2405—Russian Tartary:—Kuril islands to Kamchatka. 691—Australia, east coast:—Normanby sound and Prince of Wales channel.

These charts are issued by Mr. J. D. Potter, 145, Minories.

HOME INDUSTRIES.

The Wool Trade.—Notwithstanding the heavy direct arrivals of Colonial purchases, the second series of Colonial wool sales saw no reaction in prices. The trade is still able to lift all the wool that is offered provided the quantity offered is not rushed too heavily upon customers, and the prudent action of selling brokers in limiting the offerings at the March sales to 150,000 bales had much to do with the maintenance of prices. However good business may be—and it was never better in wool than to-day—the trade cannot be gorged, month after month, without prices being affected, and with the limit of the March sales applied to those of May, the trade is given a chance to finance all arrivals. The quality of the Australian clip is unusually high, and with abundance of wool, and high prices, there is a record in the history of the wool trade. The amount of capital required to lift the same number of bales in 1907, is very different to what it was in, say, 1895. In the latter year, the average price per bale was £11, and the total value of the Australian and Cape wool clip was £24,970,000; in 1906 the clip was only 2,071,000 bales, but the average value per bale had risen to £17, and the total value to £35,207,000, that is to say, the price had risen over 50 per cent. 1907 is certain to break all records in the sum required to lift the wools which are, and will be, available. The manufacturing world is more hungry for wool than it has ever been, and it looks as if the trade is nothing near filled up. The character of the offerings has been very good, both merinos and crossbreds being first rate. The good general buying by all sections of the trade has been one of the leading features of the series, and the way merinos have sold proves the popularity of fine wools, and in centres like Bradford there is far higher pressure in merino departments than crossbreds. The New Zealand clip this season is rather shorter than usual, and this has driven competition on to well grown, deep stapled, lustrous qualities. Probably top prices have now been reached for a time, but current rates are likely to remain steady, which is much more desirable than a rush being made to be followed by a serious fall. The present is a consumers' market, which is much better than any speculative boom. Whether the weight of offerings will break prices remains to be seen, but there is a stronger feeling of safety in present values than if prices were forced to a higher level. On the whole the outlook is sound, for consumption is undiminished, and stocks are *nil*. The woollen and worsted industries were never in a more healthy condition.

The Shipping Industry and the Workmen's Compensation Act.—Just as the Workmen's Compensation Act renders employers of domestic servants liable for compensation under a much wider range of circumstances than is generally supposed,

so it would seem to impose responsibilities upon the shipping industry of a very far-reaching character, and not as yet generally appreciated. The opening words of the Act show that it does not lay down any limits within which an accident must take place in order to make an owner liable for compensation. They run :—"If in any employment personal injury by accident arising out of and in the course of the employment is caused to a workman, his employer shall be liable to pay compensation." There is nothing here to limit liability for compensation to employment in the United Kingdom. "Any employment" can only mean employment at home or abroad unless specifically limited by some clause of the Act to the United Kingdom, and there is no such limitation. It covers employment in any part of the world, employment by a railway company in Argentina having an office in England; by a mining company in, say, the Transvaal with an office in London; by a tea or rubber company in Ceylon, to be found at an office in London, though it be confined to a single room. And in the case of shipowners, if the contention of a legal correspondent of *The Times* (March 25) is correct, the Act applies to every foreign shipping corporation which has an office in the United Kingdom. There is no territorial limitation upon the applicability of the Act, says the correspondent, any such suggestion of this kind is at once dissipated by the express provisions of Section 7, which seems to show that the Legislature actually intended to make the presence of the employer within the United Kingdom at least the principal test. Section 7 commences with this provision, "This Act shall apply to masters, seamen, and apprentices to the sea service, and apprentices in the sea-fishing service, provided that such persons are workmen within the meaning of this Act, and are members of the crew of any ship registered in the United Kingdom, or of any other British ship or vessel of which the owner or manager resides and has his principal place of business within the United Kingdom," subject to certain modifications which relate merely to procedure and subsidiary matters. Whether "a vessel" brings foreign shipowners within the provisions of the Act is by no means clear. If these words are so interpreted by the Courts there is likely to be considerable international friction, but whatever may be the case with the foreigner the Act makes the liability of the British shipowner clear beyond dispute. It looks a serious liability, but the shipowners did not protest very strongly against it during the discussion of the Bill in Parliament, so that it must be assumed that they do not anticipate any very serious payments under it, or forseeing them, see their way to meet them by insurance without serious strain.

Insurance Businesses.—The Board of Trade has just issued its annual insurance returns. The Mutual Reserve Fund is the only one noticeable by its absence, this notorious American concern having closed its offices in the United Kingdom. No notice was given to the policy-holders of the intention to close, and there must be a good many policies still running in this country. The company will no doubt meet its obligations upon them, but it has no assets here, and its record supports the recommendation of the House of Lords Committee that life assurance companies, with their head offices outside the United Kingdom ought to be required to keep a permanent deposit with the Court of Chancery. The returns now published are, for the most part, to the end of 1905. A few offices have brought them down to June, 1906; and the Friends Provident are down to November 20th, 1906. It would be more convenient if all the companies would end their financial year with December, and there seems no good why they should not be required to deposit their accounts by March 31st of the succeeding year. Even in 1905, amalgamations and transfers were numerous. The Provident Life was transferred to the Alliance; the Westminster and General to the Guardian; the Scottish Imperial to the Norwich Union Life; the Patriotic to the Sun Life; and the Yorkshire Provident to the United Provident. Last year this process of transfer and amalgamation was even more considerable, and 1907 promises to see further concentration, which can hardly be in the interest of the public. For apart from a Colonial company, the Federation Life of Toronto, only three new offices were added to the official list in 1905. The official summaries for the year showed that the premium income from ordinary business had reached £25,332,993, and from industrial £11,619,303, making a total of £36,952,296. In the course of twenty-six years the ordinary life business rather more than doubled. The increase in industrial business has been much more rapid, and the Prudential maintains its pre-eminent position. Of the total industrial premium income of £11,620,000 over £6,000,000 was received by the Prudential, while out of industrial life funds amounting to £31,000,000, the Prudential held £24,000,000. The total number of ordinary policies in force, as given in the Blue-book, was 2,068,878, giving an average of about £345 to each policy. The number of industrial policies was 25,544,045, assuring a fraction under £10 each. These industrial policies, taking the average, are little more than sufficient to pay funeral expenses. It is therefore obvious that there is still a vast number of persons in the United Kingdom, dependents, for whom no provision is made by way of life insurance. The rate of interest received in 1905 upon the ordinary life funds was £3 15s. 4d., as against £4 4s. 8d. in 1880, and upon the industrial funds £3 8s. 9d., as against £3 7s. 6d. in 1880. The accounts for 1906, so far as they have been published, show a higher return upon investments, but there has been considerable decrease in the capital value of investments, due to the low price of the securities held by insurance companies.

The Channel Tunnel and Traffic.—The refusal of the Government to approve the Tunnel Channel scheme was not unexpected. Opinions differ as to whether it could have been profitable to the company that constracted and worked it. The estimate of cost was £600,000 per mile. No doubt a good many travellers would have availed themselves of it, especially in bad weather, but if it had secured the whole of the trade now carried on between Dover, Folkestone, Newhaven, and France—it is highly improbable that it would have secured any traffic from France west of Dieppe, or diverted any between London and Belgium, Holland, and Germany—it would only have carried—assuming that the authorized maximum British mileage rates had been charged according to the various classification of the goods—imports and exports bringing in a revenue of £82,000. It is only goods of high value but small in bulk, and perishable goods, that are put on a railway, or sent by rail and steamer when direct carriage by sea is possible. Four-fifths of the trade of London, for example, come and go by sea direct, and a channel tunnel could not hope to divert any of it. There is the passenger traffic, but whether in these days of turbine boats the majority of travellers would have availed themselves of the tunnel is doubtful. Of course its advocates contend that it would attract much new traffic from both sides, and no doubt some would be attracted. But to what extent could only be settled by actual experience.

The Cotton Industry.—Easter finds the outlook for this industry still healthy. The latest advices from America make it likely that the supply of the raw material for the season ending next August will be the largest upon record, even exceeding that of two years ago, whilst the reports from other countries are encouraging. There are 1,964,000 bales in the ports, and 380,000 bales afloat of American, against 1,603,000 and 258,000 respectively last year. East Indian descriptions will be in larger supply than for some years back. The experiments of the Government of Bombay in Scinde have established that the higher grades of cotton can be grown there, and it is estimated that the substitution of Egyptian cotton in India for the indigenous varieties will increase the value of the yield. The quality of this Egyptian cotton grown in Scinde has been reported upon favourably in Manchester. In Egypt itself the crop is expected to be larger than last season. The demand for abroad is satisfactory. India is taking large supplies of Lancashire calico, as are Egypt, Italy, and South America. The only cloud in the sky, and that at present is not very menacing, is the refusal of the cotton weaving employers to pay the 5 per cent. advance in wages demanded by the workpeople. The masters have consented to an adjournment for a month, but it is understood that they will not give way. The differences have not as yet become acute.

GENERAL NOTES.

THE PROGRESS OF CANADA.—The fourteenth annual report of the Department of Trade and Commerce, Ottawa, bears testimony to the continued and rapid growth of the trade of the Dominion. During the year covered by the report there was an increase over the previous year of more than 80,000,000 dols., made up of about 27,450,000 dols. imports, and 53,270,000 dols. total exports. Both the increases in imports and exports were pretty well distributed over all classes of goods. They are, however, most noticeable as regards exports, each class or division havin participated in the increase. Nor is it only in figures of imports and exports that the prosperity of the Dominion is marked. Bank clearances, deposits, &c. are equal indicators, and are equally in evidence. Thus the total deposits in Banks increased from 555,640,068 dols. in 1905 to 626,079,335 dols. in 1906; the amount of insurances in force from 587,810,790 dols. to 630,334,240 dols.; the number of letters sent from 29,941,000 to 33,674,000; the freight carried on railways from 50,893,957 tons to 57,960,713 tons. Population, too, has increased beyond all precedent.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday Evenings, at 8 o'clock:—

APRIL 10.—"Arts and Industries in Hungary in Ancient and Modern Days." By LOUIS FELBERMAN. SIR JOHN CAMERON LAMB, C.B., C.M.G., will preside.

APRIL 17.—"Aerial Navigation." By MAJOR B. F. S. BADEN-POWELL.

APRIL 24.—"The Cultivation of India Rubber." By HERBERT WRIGHT, Controller of the Government Experimental Station, Ceylon. LIEUT.-COL. DAVID PRAIN, C.I.E., F.R.S., will preside.

MAY 1.—"The Defence of the Sea Coast from Erosion." By ALFRED EDWARD CAREY, M.Inst. C.E.

MAY 8.—"The Production of Coke and its Application in Domestic Fires." By PAUL SCHLICHT. CORBET WOODALL will preside.

MAY 15.—"Trypanosomiasis or Sleeping Sickness." By HERBERT W. G. MACLEOD, M.D., B.Sc.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

MAY 2.—"The Applicability to Indian Rivers of the Italian System of Dealing with Silt." By SIR EDWARD CHARLES BUCK, K.C.S.I., LL.D., late Secretary to the Government of India, Revenue and Agricultural Department.

MAY 30.—"Irrigation Colonies in India." By LAURENCE ROBERTSON, I.C.S., Under Secretary to the Government of India, Revenue Department.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock :—

APRIL 23.—"Social and Economic Conditions in Australia." By the HON. JOHN WINTHROP HACKETT, LL.D.

APPLIED ART SECTION.

Tuesday evenings, at 8 o'clock :—

APRIL 16.—"Joinery and Furniture Making." By A. ROMNEY GREEN. HALSEY RICARDO will preside.

APRIL 30.—"Lustre Pottery." By WILLIAM BURTON. J. C. WEDGWOOD, M.P., will preside.

MAY 28.—"Sheffield Plate and Electro-plate." By SHERARD COWPER-COLES.

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

PROF. HERBERT JACKSON, F.I.C., F.C.S., "Detergents and Bleaching Agents used in Laundry Work." Three Lectures.

April 15, 22, 29.

LECTURE I.—APRIL 15.—Water in its relation to laundry work—Hardness of water and softening agents—Treatment of boilers showing pitting—Soaps and their composition—Easy methods of examining and valuing soaps—Behaviour of soaps with water—Hydrolysis of soaps.

LECTURE II.—APRIL 22.—The alkalies used in laundry work — Their relative values and useful strengths—Bleaching agents—their composition and properties—Methods of applying bleaching agents—Their comparative value—Dangers in the use of bleaches—Methods of valuing bleaches.

LECTURE III.—APRIL 29.—The problem of washing—Textile fabrics: easy methods of distinguishing between them chemically and by the microscope—Shrinkage of woollen goods—Behaviour of various fabrics with detergents and bleaching agents—Influence of acids, alkalies, &c., on the individual fibres—Precautions to be observed.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, APRIL 8. Engineers, in the Theatre of the United Service Institution, Whitehall, S.W., 7½ p.m. Messrs. B. H. Thwaite and R. F. Thorp, "The Renard and Sourcouf Road-Train System."

Chemical Industry (London Section), Burlington-house, W., 8 p.m. Mr. H. de Mosenthal, "Observations on Cotton and Nitrated Cotton."

Surveyors, 12, Great George-street, S.W., 8 p.m. Messrs. W. Vaux Graham and Harold F. Bidder, "Underground Water. A Discussion of certain recent enactments affecting Water Rights."

British Architects, 9, Conduit-street, W., 8 p.m. Mr. Stanley Hamp, "Hotels."

Medical, 11, Chandos-street, W., 8½ p.m.

Victoria Institute, 8, Adelphi-terrace, W.C., 4½ p.m. Dr. H. B. Guppy. "Plant Distribution from an Old Standpoint."

TUESDAY, APRIL 9. Royal Archæological Institution, 20, Hanover-square, W., 4 p.m. Mr. Howard Candler, "How the Elephant became a Bishop; a study into the origin of the names of Chess-Pieces." Exhibits (figures in alabaster) by Mr. E. Herbert Fyson and Rev. E. S. Dewick.

Royal Institution, Albemarle-street, W., 3 p.m. Prof. G. H. Bryan, "Wings and Aeroplanes." (Lecture I.)

Alpine Club, 23, Savile row, W., 8½ p.m.

Designers, in the Galleries of the Royal Society of British Artists, Suffolk-street, Pall-mall, S.W., 8 p.m. Mr. H. Inigo Triggs, "Garden Design in Italy."

Medical and Chirurgical, 20, Hanover-square, W., 8.30 p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on (1) Mr. Moses Kellow's paper, "The Application of Hydro-Electric Power to Slate Mining;" and (2) Mr. Arthur Henry Preece's paper, "Electrically Driven Winding Gear and the Supply of Power to Mines."

Photographic, 66, Russell-square, W.C., 8 p.m. Messrs. E. J. Wall and C. P. Butler, "The Spectroscope" (Part I.)

Zoological, 3, Hanover-square, W., 8½ p.m.

Colonial Institute, Whitehall Rooms, Whitehall-place, S.W., 8 p.m. The Hon. J. W. Hackett, "Federal Tendencies and Developments."

WEDNESDAY, APRIL 10...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. L. Felberman, "Arts and Industries in Hungary in Ancient and Modern Days."

African, Criterion Restaurant, Piccadilly, W., 8 p.m.

Japan Society, 20, Hanover-square, W., 8½ p.m. The Baron Dairoku Kikuchi, "Female Education in Japan."

Royal Literary Fund, 7, Adelphi-terrace, W.C., 3 p.m.

THURSDAY, APRIL 11. Antiquaries, Burlington-house, W., 8½ p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Professor H. A. Miers, "The Birth and Affinities of Crystals." (Lecture I.)

Mathematical, 22, Albemarle-street, W., 5½ p.m.

FRIDAY, APRIL 12...Royal Institution, Albemarle-street, W., 9 p.m. Prof. A. H. Church, "Conservation of Historic Buildings and Frescoes."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Mr. R. W. Allen, "An Engineer's Visit to Japan and Canada."

Art Workers' Guild, Clifford's-inn-hall, Fleet-street, E.C., 8 p.m. Paper on "Educational Value of Museums."

Astronomical, Burlington-house, W., 5 p.m.

Architectural Association, 18, Tufton-street, Westminster, S.W., 7½ p.m. Mr. J. A. Marshall, "Westminster Cathedral."

Clinical, 20, Hanover-square, W., 8½ p.m.

Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. Discussion on Mr. Worby Beaumont's paper, "Petrol Motor-Omnibuses."

SATURDAY, APRIL 13...Royal Institution, Albemarle-street, W., 3 p.m. Professor Silvanus Thompson, "Studies in Magnetism." (Lecture I.)

Journal of the Society of Arts.

No. 2,838. VOL. LV.

FRIDAY, APRIL 12, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, APRIL 15, 8 p.m. (Cantor Lecture.) PROF. HERBERT JACKSON, "Detergents and Bleaching Agents used in Laundry Work." (Lecture I.)

TUESDAY, APRIL 16, 8 p.m. (Applied Art Section.) A. ROMNEY GREEN, "Joinery and Furniture Making."

WEDNESDAY, APRIL 17, 8 p.m. (Ordinary Meeting.) MAJOR B. F. S. BADEN POWELL, "Aerial Navigation."

Further details of the Society's meetings will be found at the end of this number.

MULREADY PRIZE.

The Council of the Society of Arts are prepared to offer, under the terms of the Mulready Trust, a Gold Medal, or a prize of £20, for competition amongst students of the Schools of Art of the United Kingdom, at the Annual National Competition to be held in 1908.

The prize is offered to the student who obtains the highest awards in the following subjects:—

(*a*.) A finished drawing of imperial size from the nude living model.

(*b*.) A set of time studies on a small scale, from the nude living model, executed in a short time, of varied shortly sustained poses (mounted on not more than two imperial size mounts).

(*c*.) A set of studies of hands and feet from the living model (mounted on not more than two imperial size mounts).

(*d*.) Drawing from the life, including memory life drawing done at the Examination in May, 1908.

No student will be eligible for the award who does not pass in the Examination (*d*) in drawing from the life, and who does not obtain an award for (*a*) the finished drawing of imperial size from the nude living model. The other two subjects are optional.

The works must have been executed between 1st April, 1907, and 31st March, 1908.

The recipient of a prize awarded under this trust in 1892, 1893, 1896, or 1903, cannot compete again.

The drawings, &c., are to be submitted, with other school works, in the usual manner to the Board of Education, South Kensington, in April, 1908. Each competing drawing must be marked "In Competition for the Mulready Prize," *in addition* to being labelled according to the Regulations of the Board of Education.

STOCK PRIZE.

FOR THE DECORATION OF PART OF THE INTERIOR OF A BUILDING.

The Council of the Society of Arts are prepared to offer, under the terms of the Stock Trust, a Gold Medal, or a Prize of £20, for competition amongst the students of the Schools of Art of the United Kingdom, at the Annual Competition to be held in 1908.

The Prize is offered for the best original designs for an Architectural Decoration, to be carried out in painting, stucco, carving, mosaic, or any other process.

This Architectural Decoration is to be for the side of a room or a hall, a ceiling, the apse or side of the chancel of a church, or any suitable part of the interior of a building.

The designs must be on imperial sheets. Each set must consist at least of a coloured drawing to scale of the whole design of decoration, and two coloured drawings of details on separate imperial sheets. Mere patterns or sketches of details, without the mouldings or borders necessary to make up a complete decorative scheme, will not be taken into consideration. The designs must have been made

between 1st April, 1907, and 31st March, 1908.

The recipient of a prize awarded under this trust in 1893 or 1897 cannot compete again.

The designs are to be submitted, with other school work, in the usual manner, to the Board of Education, South Kensington, in April, 1908. Each of the imperial sheets, forming a set of competing designs, must be marked, "In competition for the Stock Prize," *in addition* to being labelled or staged according to the Regulations of the Board of Education.

PROCEEDINGS OF THE SOCIETY.

SIXTEENTH ORDINARY MEETING.

Wednesday, April 10th, 1907; SIR JOHN CAMERON LAMB, C.B., C.M.G., member of the Council of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Broadbent, Denis Ripley, A.M I.E.E., A.M.I.M.E., Royal Societies Club, 63, St. James-street, S.W.
Davies, Henry A., The Hawthorns, Bradley, near Bilston, Staffordshire.
Edwards, Mrs. Helen Agnes, Flat C, Artillery-mansions, Victoria-street, S.W.
Fryer, Sir Frederic William Richards, K.C.S.I., 23, Elvaston-place, S.W.
Jayakar, Balaji Jagonnath, 41-43, New Wadi, Bombay, India.
Khaw Joo Tok, Penang, Straits Settlements.
Khoo Eu Yong, Penang, Straits Settlements.
Kirkham, Captain John Karkeek, Fontabello, Barbadoes, British West Indies.
Leckie-Ewing, William, Rupurara, Inyanga, Rhodesia, South Africa.
Lim Eu Toh, Penang, Straits Settlements.
Lim San Ho, Penang, Straits Settlements.
Lim Tek Suan, Penang, Straits Settlements.
Mackenzie, R. R., Belgaon Tea and Fibre Co., Ltd., Chittagong, India.
O'Conor, James Edward, C.I.E., Francesco, Church-road, Upper Norwood, S.E.
Ong Hun Chong, Penang, Straits Settlements.
Osborn, Lieut.-Colonel Philip Barlow, D.S.O., Zomba, British Central Africa.
Sarkar, Chandra Kumar, 31, Penang-street, Moulmein, Lower Burma.
Thio Siow Kong, Penang, Straits Settlements.
Thio Tiauw Siat, Penang, Straits Settlements.
Thomson, Sir James, K.C.S.I., M.A., Pea Hen Hotel, St. Albans, Herts.
Yeoh Ooi Gark, Penang, Straits Settlements.

The following candidates were balloted for and duly elected members of the Society:—

Anderson, James D., 17, Blakesley-avenue, Ealing, W.
Booth, Rev. James Henry, F.R.G.S., Maryport, Cumberland.
McIlwraith, Sir Malcolm, K.C.M.G., Ministry of Justice, Cairo, Egypt.
MacLean, John, 330, Smith-street, Winnipeg, Canada.
Muff, Henry, The Red House, Bexley Heath, Kent.
Wyllie, Hubert D., Cameron Septic Tank Co., 812 & 813, Monadnock Block, Chicago, Illinois, U.S.A.

The CHAIRMAN, in introducing the reader of the paper, said that Mr. Felberman was the Vice-President of the Hungarian Society of London, and there was no man alive who knew the history, the literature, the poetry, the arts and sciences, the scenery, and the sturdy people of Hungary, better than he did, while nobody was doing more to cement the friendship which had for so long endured between Hungary and this country.

The paper read was—

ARTS AND INDUSTRIES IN HUNGARY IN ANCIENT AND MODERN DAYS.

By LOUIS FELBERMAN.

HUNGARIAN ARTS.

A passionate love for Art, as well as for Music, is the birthright of every Hungarian. Right from the very earliest ages there were signs of great artistic taste and display amongst the Hungarians.

St. Stephen, the founder of the Hungarian Kingdom, and the introducer of Christianity into Hungary in the year 1000, had done a great deal during his 40 years' reign to encourage the arts and sciences of the country. He founded numerous bishoprics, abbeys and churches, both at home and abroad, the walls of which were adorned by the finest frescoes of the time.

Amongst his immediate successors, St. Ladislaus (1077-1095), the brave and chivalrous king, proved also a true patron of the arts, likewise his successor, Kolomon (1095-1114), the conqueror of Dalmatia. The last named monarch, owing to his great learning and scientific attainments, was commonly known as the "Book King."

That enlightened ruler Andrew II. (1205-1235), who granted to Hungary in the year 1222 the "Golden Bull" or the Magna Charta of Hungary, a few years after the charter was granted to England by King John, was also a great patron of the arts. Upon his return from Jerusalem as the leader of the Crusaders, he devoted a great deal of time to the re-organi-

sation of the State, and likewise to the encouragement of arts and science.

Unfortunately, owing to various internal troubles and strifes, but principally as the result of the Mongol invasion, the art treasures of the country perished and its edifices were reduced to ruins, and the Cathedral of Pécs alone bears witness to the high development of the artistic taste and splendour of that period.

The Basilica of Esztergom, built in the twelfth century, may also be considered of great artistic value, whilst the renowned church of Ják, with its noble porch, and the church of Lebény, and a number of other churches, are rightly famed in the history of art.

It may be of interest to point out here, that in those days the principal churches were erected right in the interior of the country, far away from any city; and these churches were so constructed as also to answer the purpose of places of refuge and defence against the repeated invasions of the Mongol hordes, and other tribes, and these circumstances no doubt accounted for the fact that most of the churches belonging to this period were destroyed during the country's struggles.

With the accession to the throne of Charles Robert of the house of Anjou (1308), the Italian renaissance art was introduced into Hungary both by Charles Robert, and during the long reign of his son Louis the Great, and for the next two centuries art and science prospered throughout the land.

We have only to look at one of those volumes belonging to the famous collection of King Matthias (1458-1490) known to history as the Corvina Library, and we shall at once be convinced of the highly artistic taste which was developed in those days. The wonderful ornamentation and the marvellous miniature paintings in those volumes, which were written on parchment, furnish the best proofs of the great love for art and perfection of workmanship which prevailed during the rule of this great king. No wonder that the Turks during their occupation of Buda attached such importance to the possession of this valuable collection, which consisted of 5,000 volumes.

The Hungarians will always be grateful to the present Sultan for having recently restored to the Hungarian nation a portion of this library, which had been scattered about his dominions and sacredly guarded there for centuries. The volumes were brought back to Hungary in a special train, and the occasion was marked by the greatest national rejoicings. The thanks of Hungary in this respect is due to that eminent Hungarian scholar, Professor Vàmbéry, who, with the consent of the Sultan, was entrusted with the task of searching throughout Turkey for these valuable volumes.

I understand from my friend, Mr. Joseph Offord, the well-known Egyptologist, that one of the MSS. belonging to this library is in the actual possession of Lord Leicester at Holkham Hall, and it is sincerely to be hoped that this will be restored in the near future to the Hungarian nation, the natural custodian of such a priceless document.

In a country like Hungary, where patriotism is as sacred as religion, it is quite natural that the artists of the Middle Ages should have paid equal attention to the execution of subjects relating to national and historical life, and these are represented by the frescoes at the Gisella Chapel in Veszprém and the Church of Turnicze, the latter of which shows an episode in the legend of St. Ladislaus. The fresco to be found at the Cathedral of Szepesváralja displays an ecclesiastical subject with a political background.

Of the monuments and public buildings of the fifteenth century, the Cathedral of Kassa and a few other village churches in Upper Hungary, as well as the beautiful Town Hall of Bártfa, in the same district, are the only relics of that period.

Amongst other architectural relics of the Middle Ages no doubt the most perfect specimen of the kind preserved is that of the Castle of Vajda-Hunyad, formerly the city and stronghold of that immortal Hungarian hero Hunyadi-János (father of King Matthias).

A replica in plaster of this building was exhibited at the Hungarian Millennial Exhibition, and also at the Paris Exhibition, where it commanded the general admiration of all, and was considered as the finest specimen of architecture preserved from mediæval times.

The Hungarian Government have lately raised a beautiful palace for the Royal Agricultural Museum in the town park of Budapest, after the pattern of this castle.

Amongst the artists belonging to the Middle Ages hardly any names of importance have been handed down to us, but Hungary is proud to be able to claim the famous Albert Dürer as one of her sons, for although Dürer was born at Nuremberg he was of Hungarian parentage. His father, whose name was Ajtós, was born in the town of Cyula, in the county of Békes, and resided there until he

migrated to Germany, where he took the name of Dürer, the German for the Hungarian name of Ajtós.

For over a century and a half whilst the Turks were either knocking at the gates of Hungary or had practically become its masters, the Hungarians had no time to devote to art, for to use the words of a famous poet, "They had to guard the country with their sword in one hand and to plough the land with the other."

With the final expulsion of the Turks (1699) the innate love of art made itself again potent, and two artists of great fame appeared on the scene in the persons of John Kupeczky (1676-1740) and Adam Mányoky (1673-1757), both of whom established a world-wide reputation, John Kupeczky having lived for many years in Rome and finally settled in Nuremberg, which at the time was the city of art and culture; whilst Adam Mányoky, who lived for many years and studied art in Hanover, Paris, and Holland, became the favourite painter of the King of Poland, Frederic Augustus II., also Elector of Saxony.

Both these artists cultivated the art of portrait painting, and followed the style and tendency of the Rembrandt and Vandyck schools, of which they were most able exponents. It may be of interest to know that both of these painters are represented in the gallery of the Marquis of Bath and likewise in the leading collections of Europe.

The frescoes of the Budapest University Church date from the eighteenth century, and although they have been hardly dealt with by time, nevertheless they may be regarded as fine specimens of the rococo style.

During the reign of the famous Queen Maria Theresa (1740-1780) art and science received great support and encouragement, and this was partly the case during the rule of her son, Joseph II. (1780-1790), but unfortunately the kings that followed them have shown no desire, nor did they have any inclination, to encourage Hungarian art, science, and literature; besides their time had been otherwise taken up with continual wars, which was especially the case with Francis I. (1792-1835).

Under such conditions art again lay dormant, and the few who made it their profession could barely make a living, and some of the most celebrated portrait painters had to take to painting sign boards, or to adorn with pictures the household furniture of the peasants, while the sculptors had to work in the potteries. In the Koronaherczeg - street of Budapest, there is a signboard which was painted by one of the most famous Hungarian artists, Barabás.

Towards the middle of the last century that great Hungarian patriot, Count Stephen Széchényi, to whom Hungary owes so much for its resuscitation in many directions, had also seriously occupied himself with the promotion of the arts, and his activity in this direction was followed up with the greatest zeal and energy by the late Minister of Education, H. Auguste Trefort. With a view of attaining his object, the late lamented Minister founded an Art Union, which had for its object the exhibition from time to time of pictures presented by Hungarian and foreign artists, which were disposed of by means of a lottery amongst its members.

The stormy period of 1848 and the sad days which followed put an end again for some time to the development of Hungary in general, and with it its arts and industries suffered; as soon, however, as peace was restored in the country, and by the Treaty of 1866 Hungary had a free hand in the management of its affairs, the people settled down to work, and art and science commenced to prosper once more.

In the year 1870 the first school of Fine Arts was opened under the direction of the famous painter Gustavus Keleti, and later the school of painting began its activity under that illustrious painter Julius Benczur.

The Government took the matter seriously in hand. A Fine Art society and other institutions were formed under their auspices, scholarships were granted to deserving art students, and in many cases the entire expense of their education was defrayed both at home and abroad by the Government. The result of this was that the country became possessed of some of the foremost artists in Europe, men whose names will be handed down to posterity.

Charles Lotz and Maurice Than.—Few nations indeed can boast of artists who rival Maurice Than and Charles Lotz. The gigantic ceiling painting of Lotz in the Budapest Opera House will for all times be the wonder and admiration of those who are privileged to set eyes upon this marvellous work of art, and the frescoes in the great vestibule of the central railway station at Budapest painted by Than are works of no less merit.

Professor Julius Benczur and Székely.—The historical painting by Julius Benczur representing the baptism of St. Stephen, and

the famous picture of Bartholomew Székely depicting the finding of the body of King Louis II. after the battle of Mohács, will be monuments of true artistic value for all times. To the same school as the former also belong, the painters Alexander Wagner and Alexander Lietzenmayer.

The late Count Zichy.—Another Hungarian artist of universal fame was the late Michael Zichy who, by wonderful and life-like subjects, familiarised the world with the great beauty and charm of the national ballads of that immortal Hungarian poet, John Arany.

Michael Munkácsy.—And who does not know and honour the name of Michael Munkácsy who, by the aid of Professor Szamosi, and the landscape painter, Ligeti, rose from the position of a carpenter's apprentice to the rank of the greatest of living artists. His large pictures of "Christ before Pilate," "Golgotha," and "Ecce Homo," have been exhibited and admired in London, whilst his numerous national pictures and other subjects have all attained universal fame. His pictures of Hungarian types and scenery which have brought to life some of the first poems written by Petofi, the greatest of Hungarian poets, will live for ever in the history of Hungarian art. Munkácsy, prior to being a painter, worked as a carpenter in the town of Nagy Várad, where M. Szamosi, professor of painting at the college, discovered his talent and gave him his first lessons in art. It was my privilege to be a student of this professor many years afterwards, and this led to an intimate friendship between myself and the great painter in later years. I have seen many of his original drawings there, and a tailor of the town got one of his sketches for a pair of trousers, whilst my barber had his sign board painted by this future famous artist for 3s. 6d.

Árpád Festzi.—Árpád Festzi is another artist of great fame, and his picture "Mary and Magdalen at the Grave of Christ" and his frescoes in the Palace of Justice, as well as his collosal panorama representing "The entry of the Hungarians under Árpád," are all triumphs; the last-named picture was exhibited some years ago in London.

Genre Subjects.—*Genre* subjects are represented by numerous distinguished Hungarian painters. The religious pictures of Roskovics are as famed as the portraits of Vastagh, Horowicz, Balló, Parlaghy, Karlovsky, Bruck-Lajos, Fülep László, &c.

The two last named are well known in this country, and those who may have the opportunity of visiting the exhibition of Fülep László's works in June next, at the Fine Art Society, in Bond-street, will be convinced of the great merits of this Hungarian portrait painter.

Unfortunately time will not permit me even to enumerate the host of distinguished artists in all branches that Hungary can boast of. I should, however, be doing an injustice to them were I not at least to mention their names in a casual way. They include Bihari, distinguished for gipsy and national life; Vágó, popular subjects; Margittay, humorous and modern social life; Lajos Ebner, and Jankó, famed for their *genre* subjects; Markó, celebrated for his landscapes; Telepy, mountain scenery; Ligeti Eisenhut and Tornai, for their Oriental subjects.

A large collection of paintings by Tornai, representing life in India, China, &c., will shortly be seen at the Goupil Gallery, Regent-street.

Plastic Art.—In the plastic art and sculpture, Hungary can claim to rank amongst the first countries in Europe; indeed, few nations can boast of so many famous sculptors as Hungary.

Stephen Ferenczy.—Stephen Ferenczy, in the year 1840, was the first to pave the way. Then came Joseph Engel, whose mythological and *genre* style showed great merit. The monument of Szechenyi, by this artist, which was erected in the year 1880, in front of the Academy of Science, is a wonderful artistic work. Nicholas Izsó is rightly famed for national subjects, and his monument of the poet, Michael Csokonai Vitéz, in Dereczen, is a masterpiece. The beautiful statues along the Danube quay, at Budapest, of Baron Eötvös, and the statue of the great Hungarian poet, Petöfi, by the sculptor Huszar, are admired by all who visit the Hungarian capital.

Alois Strobl and George Zala, are each deservedly famed, the first as the wonderful creator of that lovely monument representing the poet Arany, whilst Zala distinguished himself in the monument representing the Arad Martyrs, and the recently unveiled statue of the late Count Julius Andrássy.

Fadrusi will rank for all time as one of the best sculptors, and his monuments of Maria Theresa and King Matthias will always be works of the highest merit.

Architecture.—Hungary boasts of a great number of highly-talented architects, and it is

owing to them that the public buildings of the city of Budapest are considered among the finest in Europe.

Nicholas Ybl was the first to distinguish himself with his beautiful designs of the Royal Opera House, the Customs House, and the Bazaar of the fortress of Buda. Nothing can excel in style and beauty the Houses of Parliament which were recently erected along the Danube quay, at a cost of nearly £3,000,000, after the designs of the architect, Emerich Steindel. The beautiful Gothic structure is a real triumph of art, and it is a worthy rival of the Palace of Westminster, which inspired the great artist.

The imposing new buildings of the Palace of Justice, close by, which were recently erected at enormous expense after the designs of Alois Hauszmann: likewise the new Palace of Buda, commenced by Ybl, and completed by Hauszman, may be regarded as the pride of Hungarian architecture.

Altogether Budapest may be termed a city of art. There are two beautiful palaces of fine arts and a National picture gallery filled with the most precious treasures that money could purchase at home and abroad.

In addition to this there are numerous private collections both in Budapest and in the country. There is a museum of Fine Arts which will bear comparison with any of its kind, and everything is done both by the King and the Government to encourage native artists and to induce them to live at home, for the good of the country. It is fortunate that the country possesses such a gifted and esteemed nobleman as Count Albert Apponyi as its Minister of Arts and Culture. Doubtless under his able direction the arts of the country will flourish more than ever.

Hungarian Industries.

I will now briefly refer to some of the industries of Hungary. It must be borne in mind from the outset that in a country like Hungary, where about 70 per cent. of the population are engaged in agricultural pursuits, not much can be expected in the matter of industrial activity, yet the country can boast of some very important industries.

Thus the goldsmiths' and silversmiths' art is a very old one, and the country has been famed for centuries for its beautiful enamelled work and jewellery.

The Goldsmiths' and Silversmiths' Art.—A collection of ancient Hungarian jewellery, comprising sabres covered with precious stones, together with other ornaments, and ecclesiastical objects collected from the different churches, was exhibited at the late Paris Exhibition, where it created the greatest interest, its value being some millions of pounds.

The Hungarians, being of Asiatic descent, are rather fond of wearing articles of finery, which in this country are confined to the fair sex. The poorest peasant will have a double row of gold or silver buttons on his Sunday attire. The picturesque Hungarian costumes lend themselves very much to ornamentation, and, as must be remembered, the military hussar uniform in the armies of the world is practically copied from the costume worn to the present day by the peasantry throughout Hungary. Of course, the costume varies according to the means of the wearer, and naturally on fête days it is of a more elaborate kind. The gala uniforms of the nobles and gentry are literally covered with the most precious stones, and very often a costume of the kind represents a fortune, and is handed down as an heirloom.

On the occasion of the visit of His Majesty the King, whilst Prince of Wales, to Hungary, His Majesty was greatly taken with these uniforms, and fully made up his mind to purchase several of them and bring them home to England, but much to his surprise he was told that the cost of a single uniform alone with all its ornamentations would come to thousands of pounds. In olden days the Magyars when in the battlefield would attire themselves in their gala dress covered with precious jewels; even the saddles of their horses would be studded with rubies, emeralds, and diamonds, and during their repeated incursions into Germany the Teutons quite enriched themselves by the capture of a few Hungarian warriors or their horses, for the safety of which they fought with fanatic bravery, as nothing is so dear to a Hungarian as his horse.

Metal and Iron.—The metal and iron industry is a very old one in Hungary. Some of the gates and ironwork to be seen in different parts of the country, dating back to the fourteenth and fifteenth centuries, are wonderful specimens of artistic skill. The enormous gate of the church of Pozsony is the finest example of the kind.

Earthenware and Pottery.—These are two very old industries in Hungary, and there is hardly a village in which pottery is not manufactured. The articles are generally made by the peasantry and are ornamented with simple

patterns depicting the daily life and surroundings of these primitive folk. Recently means have been taken to raise these industries to a higher artistic level, and the majolica manufactured by the famous Zsolnay, and also that known under the name of Herend, have found their way into the best households throughout the world, and are admired for their original and artistic designs.

It is noteworthy that no efforts have been made to deviate from the old pattern; on the contrary the articles mostly in demand are those which are faithful copies of the peasant household objects such as the *Kulacs* (water pots) and quaint *Korsó* or water bucket and their like.

Leather-work.—In this industry the Hungarians excel, and the number of articles made of leather in daily use by the peasants is marvellous in their beauty and variety of colour. The leather bag which carelessly hangs down over the shoulder of the peasant dandy when going to market; the tobacco pouch with its long fringes which hangs from his waist; the whip which he holds in his hand, or the smart and ornamented top boots which he wears, are all perfect specimens of workmanship and skill. In a variety of household articles leather and skin play an important part, and the Kulacs and other objects will generally be covered with skin neatly embroidered and stitched.

Besides saddlery and harness a very great industry in leather is the manufacture of the "Bunda." This is a long cloak made of white sheepskin, dressed with the wool inside, while the outside leather, white as snow, is embroidered generally in red and green, the national colours. The "Bunda" is worn throughout Lower Hungary by men and women alike, and is as useful as it is ornamental. For the shepherd it forms his cosy corner in the wide open plains when he cannot find a hut or a cot to shelter him. For many years I wondered why these cloaks were not imported into England, and I am pleased to say that of late I have seen here several lady's garments made after the pattern of the "Bunda." The Ködmöny is made of a similar material, but should be tight fitting.

The "Szür," made of a kind of homespun wool, richly ornamented with embroidery, is an article for which there is a great demand; whilst the "Guba" is the winter garment, of long rough wool, which the swineherds, shepherds, and others, who cannot afford the leather "Bunda," wear in certain parts.

The furrier's trade is also a very old one in Hungary, and it is noticeable that some of the largest furriers in London are Hungarians.

But the most popular industries in the country are those known under the name of home industries. These include weaving, linen, embroidery, needlework, lace, basket weaving, and the making of a number of household articles, for which the Hungarian peasants have been famed from time immemorial.

The beautiful workmanship of table covers and centres, and the exquisite taste shown in the stitchery and patterns of the lace work could not be outrivalled. The most celebrated embroideries are mostly known under the name of "Kalotaszeg Varottas," which come from Transylvania.

The "Katrincza" on the pinafores made and worn by the peasantry in the southern part of Hungary, is admired even when worn by the greatest ladies in the land. The "Tyillim," or little carpets made by the Servian peasantry inhabiting the district of Banat, are most beautifully worked, and the combinations of colour and execution make them eligible to adorn the drawing-room of the richest, the designs of all these articles of home industries having been adhered to for centuries.

In olden days the peasants only made those objects for their own use, and would not be induced on any account to part with them, but on the initiative taken by the late lamented Empress-Queen, and the members of the royal family, including the Archduchess Isabella, and by the support of some of the leading members of the aristocracy, these home industries were developed, and the results are now to be found and admired throughout the world. I am proud to say that I can claim the honour of having introduced these Hungarian industries into this country by the generous support of H.R.H. the Princess of Wales and several members of the English royal family.

The Government in Hungary is doing everything to encourage the home and art industries, and has established numerous industrial schools throughout the land where the pupils are taught by distinguished trained professors in all arts and handicrafts. Prizes are offered for original designs which are afterwards manifolded and published with the necessary instructions in costly monthly volumes and distributed throughout the land.

In this respect our art industries owe a great deal to the indefatigable efforts of the Secretary of State, Mr. Joseph Sterényi, who has risen to his present position by hard and

honest work for the cause which he has so warmly advocated.

The Hungarian Arts and Crafts Society is another national institution under the able direction of M. Jenö de Radisics, which has contributed so much to preserve and encourage the artistic trade in Hungary. In the spacious museum are exhibited some of the rarest specimens of ancient and modern national workmanship in all branches, such as furniture, jewellery, embroideries, and other decorative works of art, and in addition large amounts are expended annually in the purchase of foreign articles of arts and crafts which have gained rewards or are otherwise noteworthy.

Flour Mills.—In connection with the more important industries associated with agriculture, there should be mentioned the world-renowned steam flour mills, which up to now cannot be surpassed in any country, and, thanks to the good quality of Hungarian wheat and to the mills, Hungarian flour is preferred to any other in the world.

Distilleries.—Another industry in which Hungary is great is spirit distillation. You find stills in almost every village, and the Hungarian peasant's national drink, *Pálinka*, a kind of spirit made of rye and barley, is a splendid substitute for Scotch whiskey.

Sugar.—The sugar factories and refineries are most important, and form leading industries of the country; in addition to which there are factories of tobacco, petroleum refineries, with numerous chemical and other works throughout the kingdom.

Hungary, however, admits that it is by no means an industrial country, and though there are a number of cloth weaving mills there is a great want of textile industries. The country which produces sufficient raw wool not only for the manufacture of articles for home use, but to supply also the foreign market, yet has not its own factories, and now exports the raw material only to buy it back at a heavy increase made up into fabrics. The yearly importation of textile articles alone is remarkable, amounting to over 375 million kronen, most of which is imported from Austria. The Hungarian Government is endeavouring to establish factories at home to supply the demand, and is desirous of granting special privileges and monetary assistance to manufacturers.

The people of Hungary are somehow not enterprising enough or have not the necessary capital at their command, and though the Government is doing all in its power to foster the textile industry, the progress made in this direction is somewhat slow, and there is an excellent opportunity for English capitalists to extend their business in Hungary; the experiment would prove most remunerative in every respect. There is all the more reason for this as the Hungarians, who have always from time immemorial been admirers of the English race, give preference to any articles manufactured in England. Even now a large amount of British wool stuffs is bought in Hungary, but of course the Protection tariff of the dual monarchy handicaps very seriously importation on a large scale.

Those English firms who some years ago founded branches in Hungary for the manufacture of agricultural implements have had no reason to regret their action, and English people would do well to take advantage of the opportune moment before they are ousted by Germany.

In Hungary, foreign invested capital is guaranteed by the laws of the country, and when it is added that such an eminent person as Francis Kossuth—who, by his education, might almost be regarded as an Englishman—is at present the Minister of Commerce, it is evident that now is the proper moment to take a decision in this direction.

DISCUSSION.

The CHAIRMAN, in opening the discussion, was sure all had followed the paper with the greatest pleasure and interest. The author's mention of the Magnate dresses had reminded him of an occasion on which a large number of foreigners, including Englishmen, were received in Hungary by the Minister of Commerce, who appeared in a dress like that worn by the Earl of Leicester at the Court of Queen Elizabeth. It was of scarlet satin, slashed and embroidered with gold; and he remembered that when the minister appeared on the platform to address the assembly, he could not help saying to one of his neighbours "Where is Queen Elizabeth?" Those present who happened to be in Budapest eleven years ago must have followed the paper with particular interest, because at the Millennial Exhibition which was then held the whole of the treasures of Hungary in architecture, art, and industry were spread out before their eyes. Some might wonder how it was that the treasures of architecture could be seen, but the author had given a hint on that subject. There were produced at the Exhibition in the most marvellous manner the chateaux, the churches, and the town halls of Hungary, and the closest inspection would have left

one still in doubt as to whether the buildings were the real thing or not. Although the buildings were only reproductions, they were filled with all the real treasures gathered from the churches and private houses of Hungary; and although Mr. Felberman said that most of the treasures of the country were destroyed, the remnants were sufficient to fill the splendid palaces in question. Ancient art silverwork was to be seen, and sculpture, enamels, illuminated books, croziers, crosses, monstrances, and chalices, all in the most splendid preservation. He thought the Hungarians must have been very great in silver, ivory, and woodwork. Family portraits, ancient paintings, china, most beautiful glass, armour, weapons, hunting horns, drinking horns, which were really architectural monuments, they were so big and so elaborate, were also to be seen. He did not know what the drinking capacity of the Hungarians in olden days must have been, for the drinking-horns were simply enormous. Lastly, many specimens of furniture were on view. Side by side with those treasures were to be seen the embroideries, and the other products of native industries which the author had described, displayed in modern buildings, which also were very beautiful and picturesque. He bought some of the embroideries in the belief that such things were not to be obtained in England, but was disappointed to find a few months afterwards similar goods in immense quantities in a shop in St. Paul's Churchyard, which showed how very quickly things of that sort were discovered by English tradespeople. Budapest, as a city, could be likened to Edinburgh. If Prince's-street could be imagined, with palaces all along the front, the Emperors' Palace on the opposite height, with the old Castle of Buda, and running between, not the lines of the North British Railway Company, but the splendid Danube, flowing at the rate of six knots an hour, they would have a very good idea of what Budapest was like. Strolling along the streets of Budapest, the very best of everything was to be seen in the shops, while along the streets were electric trams of the latest design. There were curious little stations for the underground electric railway, which he thought were an example which might be followed everywhere. Instead of the ugly structures to which we were accustomed, the entrances to the underground railway stations in Budapest were most airy and beautiful, modelled apparently on the companion ways leading down to the saloon of a big steamer, made of majolica ware, and kept thoroughly clean by being well syringed every morning. An exhibition of the works of the great painter Munkacsy was also to be seen, and if the visitor strolled along the quays he came to that palace of Parliament which Mr. Felberman had so graphically described. He personally regarded that palace as the finest example of modern architecture to be seen in Europe. There was in the building an extraordinary combination of one style with another, a combination of a dome with what English people would call early English, with pointed arches and lancet windows, an entirely harmonious effect being obtained. If some of the audience could only see that building he was sure they would desire that similar buildings should be built in this country. He was a little enthusiastic about Hungary, but he was perfectly certain that anyone who visited that country would also become enthusiastic.

Mr. R. J. Mackay said it was one of the greatest pleasures of his life to look back on the happy weeks he spent in Budapest, especially to the Millennial Exhibition, which the Chairman had so graphically described. The Library of Matthias Corvinus which was there exhibited, and which consisted of a complete collection of the arts and literature of the time, was a particular source of interest to him. Matthias Corvinus was one of the greatest leaders of all times, and a wonderful man in every way. He advised any of the audience who had not been to Hungary to go there, because he was convinced they would return with the same delightful experiences as all the visitors who went to that interesting country.

Mr. Adam Scott had been particularly interested in the author's statement that the churches in Hungary in olden times were built so far away from the towns, because it threw a light on a puzzling question. An old German medal of the seventeenth century was brought to him, which had been struck in commemoration of the Jubilee of the building of an Evangelical Church in a German town. On one side there was a representation of a church, with the words, "Ach wie nahe" at the top. On the other side there were a few houses representing a town; on the corners were two fortified churches on hills, with paths leading from the town to the churches, and people going along them; and on the top were the words, "Ach wie weit." The medal was in the possession of the British Museum.

On the motion of the Chairman, a hearty vote of thanks was accorded to Mr. Felberman for his interesting paper, which Mr. Felberman briefly acknowledged, and the meeting terminated.

THE PRESENT STATE OF PHOTOGRAPHY.

By Chapman Jones.

In looking back at the course of the development of photography, it is interesting to compare the progress of the art, that is its application in picture or record making, with the progress of the science, that is the study of its underlying principles, and the influence of each upon the other. It is not putting the case too strongly to say that photography has generally been regarded by men of science as too insignificant a

matter for their serious attention. With a very few notable exceptions they did no more than make a casual suggestion now and again, treating it in short as a menial servant or else disregarding it altogether. The natural result is that photography was worked out empirically by those who were unable to bring anything more than the most superficial knowledge of general principles to their aid.

Silver salts were used because some of them were known to darken by exposure to light. Iodine was used because it was known to change the colour of the surface of metal plates. And so by feeling about with these things—one might almost say fooling about, but that it would be disrespectful to the early workers to whom we owe more than we can ever tell—by feeling about with these things there was evolved a photography, the full character of which the discoverers themselves had no idea of.

And we may well ask how much further have we advanced than they did? Fundamentally, not at all. We have only perfected their methods. We still use nothing but silver salts, except perhaps as mere adjuncts, for camera work, and no other metal has been shown able to replace the silver. Of course, silver may be exceptional in this, but it seems that it would be more in accordance with general facts if this property were shared by a great many metals, if not all metals, in various degrees. Silver may stand at the head of such a list, and the fact that it is the best known conductor of heat and electricity may have something to do with it. But whether silver is one of many or one alone, it appears to have been an exceedingly fortunate circumstance that it was the metal worked with from the earliest days of photography.

The same clinging to mere empiricism, or the practice of the art without regard to the principles it is based upon, is shown in the treatment of negatives during and after their development. General practice, and the procedure recommended on what is often called "high authority," is too often based on the sands of assumption instead of the rock of fact. Like jerry builders and those who patronise them, appearance is the only criterion of success. The "clearness" of a negative is judged of only by its appearance, so that instead of being clean it may be full of substances ready to produce visible stains by circumstances that can hardly be avoided, and that are without doubt uncertain. Intensification results are judged of merely by the appearance of the negative and perhaps of the print it gives. The gradation may be falsified or it may be improved, but it is all haphazard, the resulting image may be such that it changes from week to week, but so long as the intensified negative looks nice when it is done, the method used is recommended as excellent.

These natural and perhaps inevitable results of the empirical study of the art rather than attention to the science of photography, might be multiplied again and again, for even notable investigations have been made with the sole aim of finding an exact method of determining certain properties of plates that have no definite quantitative existence, but depend entirely upon circumstances, and so far as practical work goes, on very variable circumstances.

But there is something to be said on the other side. There have been almost all along a few enthusiastic if little-appreciated workers, and at the present time there are many more. The chemical constitution of developers has been elucidated, so that it is generally possible to tell whether a substance will or will not serve as a developer before it is actually put to the test. The result of this is that, instead of being limited to one or two developers, the character of organic developing substances has been generalised, and there are so many known that will serve that the difficulty is rather to select the most suitable. As would be expected, they are not all alike in their action. They differ in their manner of development, and, what is less often recognised, in the character of the substances that they are changed into by the process of development or oxidation. The residual products should, of course, be readily soluble in the liquid employed, so that they may be easily removed.

We know a little of the chemistry of some of the more common changes that take place during the making and treatment of negatives, though the knowledge is rarely taken advantage of. A great deal of good fundamental work has been done with regard to colour, its effects and its reproduction, but even here there is now a tendency for the art to overwhelm the science, and for the practice to become merely empirical.

Perhaps the most obvious and immediate need is the bringing together of the experiences of the everyday worker and the investigations and speculations of the investigators. Some researches bear on the very face of them the indisputable evidence that their authors are not practical photographers. It is doubtless, partly due to the fact that so few persons who possess the practical knowledge and skill which make a good photographer, have also the necessary acquaintance with scientific facts and methods of exact investigation coupled with the desire to help forward our knowledge of the subject, that the scientific side of photography receives such scant attention from the practical workers. But the shallow empiricism that looks only to the immediate and superficial result is still the chief guide, not only of those who have been taught by experience to rely upon it, but of others who merely follow the fashion.

THE BRITISH INDIAN COMMERCIAL MISSION TO SOUTH-EASTERN PERSIA.

III.

Russian Competition.

The competition of the State-assisted Russian trader with the British and British-Indian trader is serious. The Russian Government has for years been

working at the Persian problem in its own way and one of its axioms is the absolute identity of trade and politics. It has taken special steps to encourage the importation of manufactures into Persia, and Russian trade has all the advantages that result from every form of State aid. According to the ideas worked to their utmost capacity by Count de Witte, it is subsidised in a way that astonishes all the world. he raw produce for the mills and factories, the very food stuff for the operatives, but not for the mere peasant or townsman, are admitted into Russia from certain regions at specially low rates, while a formidable Customs tariff is opposed to the importation of any competing manufactures. Russian-made goods are granted special rates over Government railways and for carriage by Russian ships, whose owners receive heavy bounties. In addition to this, the Russian manufacturer, when he is not exporting to a free trade country, is granted rebates equivalent to the Customs dues he has to pay. The Russian State bank assists, at rates impossible to an ordinary mercantile bank, Persian traders exporting merchandise into or buying goods from Russia.

The part of Persia contiguous to Russia is much richer naturally, and much more developed than the south; it is more thickly inhabited, the people are more advanced, the trade routes are shorter and in every way better than those of the south. Lines of railways run down to and touch the Persian frontier, connecting the caravan routes with the Russian manufacturing centres. Now we are to have a motor car service for the carriage of merchandise running into Persia from Russia; her roads are made; a concession has been granted; the scheme is near completion. There are no breaks in the telegraph, nor any paucity of lines, so depleted markets can thus be quickly replenished from the northern centres of Russia under three months from date of ordering, whereas it takes an Indian or English merchant from at least six to eight months to do the same, a serious consideration, as it not only means capital locked up for twice the period, but very often loss of market.

In addition to the various subsidies given to manufacturers in Russia, and the special rates accorded to their goods over the State railways to the frontier stations, there are a number of ways in which the Russian Government and the Russian Bank assist not only the Russian merchants but their Persian customers as well. Moreover, in the north and south alike, Russian consuls are as active as any merchant in pushing the interests of Russian trade, and the introduction into South-Eastern Persia, by the Russians, of methods of trade finance that have hurt us seriously in the west and north cannot but be viewed with uneasiness. Unless the British and Indian Governments see fit, as already stated, to do something for the fostering of our trade in Persia, British interests may suffer in the future even more than they have done in the past.

The Russian Steam Navigation Company, trading from Odessa to the Gulf ports is given an annual subsidy, for the carrying of bounty-fed goods, which comes to £4,000 per trip. The Suez Canal dues are also refunded. Thus the Russian shipper gets an advantage which ought to enable him to put his goods on the market at rates by which he could outbid all competitors. Nevertheless, he is not quite able to do so, though he has succeeded extremely well, especially in the northern provinces, in pushing sugar and certain lines of cotton prints and Turkey reds, which latter the Persians seem to think are of better quality than English goods of the same character. The Russian manufacturer, like the German, is willing to execute small orders and to make new patterns if asked to. He foresees new demands to meet them; in a word, he does not force what he has down the throats of his customers, but supplies what is wanted.

Matters Consular.

Mr. Gleadowe-Newcomen is of opinion that the time has come when we should make diligent efforts to maintain our supremacy in South-Eastern Persia. He compares at length the consular arrangements as pursued in Persia under the Foreign Office with those under the Indian Government, to the marked disadvantage of the former, and suggests the advisability of making a Consul-Generalship for Kerman and Persian Baluchistan, bringing Yezd (with a Vice-Consul of its own) under its jurisdiction, as well as Bander Abbas, in all matters commercial. The appointment of Vice-Consuls at Yezd and Bam, with consular agents at Sirjan, Rafsinjan and Bampur is also recommended, as well as a Commercial Attaché at Teheran. Many other detailed recommendations on a variety of points are made, which undoubtedly require careful consideration, but want of space precludes notice of them here. The following points for increasing in Persia the knowledge of India and her manufactures are advocated, viz.:—

(1). At every consulate or consular agency a showroom to be set apart for samples of Indian goods with prices and full details clearly marked in Persian, shewing place of origin and from whom obtainable.

(2). Consular officers to be provided by the Indian Government with funds and with collections of articles intended to be offered as gifts to Persian gentlemen and their servants who have shown themselves friendly to the British Indian cause. These form the *Toshakhana*.

(3). The touring of India by Persian boys, who have been sent there to be educated (as mentioned above).

(4). The encouragement of Persian merchants to visit Indian trade centres by the granting of assisted passages to and fro.

Communications, Roads, Posts, and Telegraphs.

Of the three prime wants of Persia, not the least is the improvement of communications. Practically there are neither waterways nor roads, with the exception of three short stretches in the north—Resht-

Teheran, Teheran-Meshed, and Ashkabad-Meshed—where rough waggons are now, and motors will in the future be used. Camels, mules, and donkeys are still, in the twentieth, as they were in the second century, the carriers of of Persian commerce. The great caravan routes urgently require improvement, though, of course, a network of good roads, after the fashion of Europe, America, or even India, can hardly be expected soon from a thin and widely scattered population of ten millions, whose annual consumption of imported articles amounts to only Rs. 7½ per head. But as to mere improvement of tracks, Kafilas have for ages worked their toilsome way along river beds and valleys, over mountain passes and along certain tracks across the plains. In time a faint and indistinct groove has been worn in the ground, and at night the silent camels find their way across the desert by scenting the odour left by those preceding them. With the worst parts of the inland roads made easy, the costliness of transport alike in time and money would be reduced.

It is a different thing when one comes to the consideration of the tracks connecting the coast towns and ports with the towns on the plateau. The only epithet that can be applied to these tracks, whether from Bander Abbas or Bushire, is "terrible." Hence the assistance of the road builder is essential. By shipping goods to Bander Abbas and Mohammerah and thence inland, a considerable saving would accrue, provided proper roads were available, and wheeled traffic could run. Goods for the interior are sometimes delayed for months, waiting for pack animals or until a sufficient number can be collected to form a large caravan and thus ensure immunity from attack and robbery. And, lastly, the lack of a properly organised system of transport causes delays, especially at Bushire and in a lesser degree at Bander Abbas. Mr. Gleadowe-Newcomen is of opinion that money spent in improving the port and its communications will be a profitable investment, both to Persia and to India. He advises that the Government of India apply at once for a concession to construct a road to Kerman in Minab, Rigan and Bam, the road to be built on a proper level for wheeled traffic. This would not only facilitate and expedite trade, but open up a large tract of country for the growth and exportation of cotton, gums, &c., by bringing it in touch with Bander Abbas. Later on, extensions might be made up to Teheran, Seistan and Khorasan, and once the road was made it would be found feasible to run motors or some other description of traction cars for the carriage of merchandise. The exploitation of the mineral resources of the country, and the erection of mills and factories, would thus be rendered possible by the opening up of good road and wheeled traction.

If it be desired to develop the Quetta-Nushki route to its utmost capacity, the railway should be continued to Kala Robat, on the confines of British territory. This would mean that the time occupied on the journey to Seistan would be very greatly reduced, while the land trade of India with Persia would receive a very great impetus. The whole of Persian Baluchistan would be commanded, and Bam would then be only about 150 miles and Nasratabad about 90 miles distant from a British railway terminus. The line could be laid along the existing caravan road.

At certain seasons of the year in certain localities, though their operations are not confined to those places, the highways of Persia are infested with brigands. These men are seldom particularly bold or enterprising in their work. Large and well-armed caravans or armed Europeans have little to fear. Travellers moving singly or in small companies, together with the Persian post, when there is reason to believe that it carries valuables, are constantly being looted in the spring and autumn, which are the times when the Nomads are generally on the move. There is no difficulty in explaining or accounting for the insecurity of roads, speaking generally. Every year the Government of the Shah apportions large sums of money for the establishment and equipment of guards to secure the safety of the roads. Almost the whole of this money is embezzled by the Persian officials, little indeed reaching the hands of the road-guards, who are forced, in order to live, to emulate the lawlessness of the freebooters they are supposed to restrain. The story is an old one in Persia. It was the unpaid road-agents who long ago showed the Mongols and Turkoman hordes the way over the deserts and through the mountains where, had the officials of the Shah been passably honest, the former must have perished.

The Imperial Government is, however, bethinking of responding to the pressure brought to bear on it, and devising some means of redressing the abuse. Mr. Gleadowe-Newcomen suggests the establishment of a *gendarmerie*, officered by British, for the southern provinces, after the fashion of the Persian Cossack Brigade, which was raised in the northern provinces, officered by Russians, and brought to a very high pitch of efficiency. An alternative system would be to pay the Nomad chiefs a subsidy, and make them responsible, under heavy penalties, for guarding the special roads within their district.

The postal service in Persia has undoubtedly improved in certain sections, since it has been taken over by the Belgian administration. Most of the towns now enjoy a weekly post, whilst the chief cities have a bi-weekly service. A parcel-post service between Persia and Europe *viâ* Russia exists, but this is not very satisfactory, as all parcels are opened at the Russo-Persian frontier, and losses through robbery are frequent. Matters would be improved if there were a European agent on the frontier to look after the taxing and forwarding of the parcel post. At present there is no through foreign parcel post from the Gulf ports to the interior, a most unsatisfactory state of things The postal rates too for local parcels are extremely high. The Belgians are trying to bring about still further improvements in the service, and these are bearing fruit. Further

improvement is, however, still possible, *e.g.*, between Kerman and Bunder Abbas, where the distance might be covered in less than a week, *i.e.*, less than half what it takes at present. Why Bam should not be linked up with Seistan, to the great benefit of India, whose postal service would thus be joined to that of Eastern Persia, it is difficult to understand.

Telegraphic communications have been greatly improved and extended of late years. In addition to the main Indo-European line from Teheran to Bushire, a second three-wire line, known as the Central Persian line, has been constructed. It branches off from the former at Kashan and runs, *viâ* Yezd, Kerman and Bam, to Kala Robat, on the British-Perso-Afghan frontier, all the important towns, *en route*, being connected. Robat has been connected with Nushki and the Indian system, since the MacMahon Mission. It is further intended to establish a more southern land connection by way of Rigan, Bampur and Kuhak, to meet the line which will be constructed from Karachi and for which a survey has been already made on the Indian side, *viâ* Panjgur and Kolwan.

There are various minor links mentioned in the present Report, one of the most important being the opening of a telegraph office at Bander Abbas. This suggested reform it is believed is now being carried out. A detailed notice of the various recommendations in regard to the telegraphic network, important though they are, is beyond the limits and scope of this summary.

ENGINEERING.

The future prospect of Persia is to a great extent in the hands of the engineer, who will build the road and irrigation works that are so urgently needed and exploit her mineral resources.

Irrigation.—Given a sufficient supply of water, Persia, much of which possesses as perfect a climate as could be desired, and a soil which is naturally fertile, would be a garden. The problem is now to get the water, for at present the arid zone is spreading and every year sees an addition to the dreary numbers of ruined and abandoned villages and *kanats*. The construction of the underground canals is very slow, primitive and liable to accidents; there is only one advantage and that is, that the water flowing in deep covered channels is less liable to evaporation. The rainfall of Persia is not great, it may perhaps reach eight inches a year in the south-east and twelve to fourteen in the south-west. What rain does fall, except in the form of snow, runs off the hills at once, for they are generally bare of trees, vegetation or soil, and runs to waste. No efforts have been made for centuries to build reservoirs or dams or to ensure in any way the snow or storm-water, though there are scores of places in the mountainous land where sites for dams and reservoirs could be found.

Railways.—As to this Mr. Gleadowe-Newcomen's opinion, is that it would not be difficult to construct a railway from Bander Abbas to Bam. But it would not pay to build any line in Persia unless the production, population and trade of the country were at least doubled. According to the plan sketched out by the Russians there are three contemplated schemes, one from Baku to Teheran, viâ Kisht; one from Julfa on the Trans-Caucasian border viâ Tabriz, Teheran, and thence through Kashan, Ispahan, and Shiraz to Bushire on the Gulf; and the third taking off from the Russian Trans-Caspian Railway, near or at Ashkabad viâ Meshed and Seistan, through Persian Baluchistan to the Gulf, touching the sea at Minab or Bander Abbas.

These projects are (as regards two of them, at least) so plainly inimical to British interests that it is difficult to regard them as within the range of practical politics.

Harbour Construction.—Bander Abbas is superior to Bushire, alike as a port and gate of entry into south-east and Central Persia, but improvement is needed by dredging operations and the building of a good pier and a breakwater, the latter to ward off the formidable surf when the wind is strong from the south-east. The port of Bushire, where ships anchor in the open roadstead between three and seven miles from the Customs wharf, could also be improved at a small cost.

Mining.—The contorted strata of the mountains with which Persia is seamed are certainly highly mineralised, but these mountains are very little known. In places copper, turquoises, and other minerals are being worked after methods even more crude than those of two thousand years ago. Among minerals cited by Mr. Gleadowe-Newcomen (with particulars of the localities) are asbestos, copper, lead, zinc, iron, sulphate of copper, coal and borax.

CUSTOMS.

The new tariff, both in the export and import trade of Persia, is in many ways unfair to British interests. Some of the chief Persian products taken by the British Empire are grains, linseed, sesame, and opium. In all these the new tariff has increased taxation from 3½ to 20 per cent., while exports taken almost entirely by Russia, such as rice and cotton, have been freed from taxation or nearly so. It is the same with imports. Indian tea, for instance, which formerly was taxed at 5 per cent. *ad valorem*, is now taxed from 50 to 90 per cent., while the duty on petroleum, almost purely a Russian product, has, on the other hand, been reduced from 5 per cent. *ad valorem* to 1½ per cent.

Articles produced in common by both Empires, such as piece goods for instance, pay equal duties. Yet, even so, this works to the advantage of Russia. Russian goods are more costly at the ports of entry than Indian or Manchester goods. So the substitution of a tariff of charges by weight for an *ad valorem* charge compels the importer of a ton of cheap British goods to pay the same duty as a ton of dear Russian goods, which is manifestly unfair.

As a whole Mr. Gleadowe-Newcomen declares that

the result of the introduction of the new tariff and its administration by European officials has so far been an increase of revenue, but it is open to doubt if it has helped trade generally. The new tariff, he further contends, is based on an extremely complicated system as opposed to the old simple method of taxation by value.

This ought to be changed, simplicity in such matters being essential in a country where the traders and people are centuries behind their times.

The "Règlement Légal" consists of 112 articles, and a good many of these are objectionable and threaten, as in Bushire, to bring the seaborne commerce of Persia to a standstill. The rest are either obscure and ill-defined or unworkable and unsuited to the conditions obtaining in Persia and the Gulf ports. They have been imported bodily from the Customs rules in Belgium, a small and civilised country where railways have abolished distance, and ships work alongside wharves, close to the Custom-house under the eye of the Central Administration. In Persia (to go no further than the last item) the Central Administration to which all appeals must be referred, is at Teheran, a month's journey or more from the ports.

The language in which customs notifications are printed is French, whereas Mr. Gleadowe-Newcomen contends with some force that seeing what England has done for opening up, safeguarding and developing the Persian Gulf trade, the least that can be done is to admit the use of English as well as Persian, which is understood by all traders whether natives of India or Persia.

Lastly may be mentioned the subject of the abuses of farming out the road posts and the revising of interior dues which, though absolutely illegal and even contrary to our Treaties, are still levied.

The various trading centres are then reviewed at length in the Report, each locality being taken in turn alphabetically, and its circumstances, position, trade, industries, disabilities, possible improvements, &c., being carefully described and analysed. This is succeeded by a review of all the chief articles of export and import.

RESUMÉ.

It is evident from a study of trade movements in Persia, that British commerce with that country is not in a healthy condition. It has expanded but little during the last fifteen years; it has been practically stagnant during the last four years, and the latest available statistics show a slight actual decrease. This slight decrease becomes a very great relative set back, when compared with the enormous advance made by Russian trade with Persia of late years and especially during the years 1900 to 1904.

Roughly, the value of the entire foreign trade of Persia in 1903-4 was 10⅝ million sterling, of which Russia's share was 5⅝ and England 2½ million sterling. The greater part of British and Indian trade is through the Persian Gulf ports, and the movement of trade in the Gulf, therefore, offers a very reliable rough index of the movement of British trade with Persia. Nevertheless, the position of the British trade is not so bad as might be inferred.

Trade between Russia and Persia is greatly facilitated by comparatively easy communications (including railways), between the two adjacent countries and the practical identity of the two peoples. Added to this is the fact that these northern tracts are the richest and most prosperous and that Russian trade is carefully nursed and bolstered up by artificial aids.

As matters stand, British trade with Persia is, heavily handicapped through the enormous difficulties in landing goods at the Gulf ports and securing their transit inland. Southern Persia is poor, undeveloped, and patrolled by robbers. The trade of the empire is not assisted by British, Imperial or Provincial Governments (as in Russian trade by the Russian Government), either financially or by bounties, rebates, and other artificial means. Lastly, British consuls do not always take that interest in the development of commerce that Russian consuls invariably do.

Generally speaking, there are in Persia, more especially in the south, want of roads and security, costly transport, a faulty postal service, and an incomplete telegraph service, coupled with the fact that there is virtually no law (as we understand it) in the land, custom and the Koran taking its place, and bribery and the strong hand ruling everything; these have all militated against the development of the resources and trade of Persia. There is some attempt being made to improve this state of affairs in the Kingdom of the Shah, and this should be encouraged and fostered by all concerned.

Before this can be fully achieved the following points should be noted:—

(1). While recognising that the British Government has been "over-reached" in the drawing up and imposition of the Tariff and the Règlement, they and British and Indian traders are recommended to accept the situation to a certain extent and insist on its being carried out, as well as the abolition of illegal taxes and the erection of proper warehouses, bonded and other.

An international Court of Appeal where Customs questions are concerned, ought to be appointed at the chief ports to avoid reference of every point to Teheran. The Customs tariff cannot be altered for years to come, but the "Règlement" (though it has been accepted by us), should be revised.

(2). Improvements at the ports of Bander Abbas, Bushire and Mohammerah are a necessity, together with an improvement in the system of lighterage.

(3). Modifications are necessary in the present methods of Customs-house working, and greater facilities are required by merchants.

(4). Communications require urgent attention. The Indian Government should in the south, follow the example set by Russia in the north.

(5). More determination and earnestness, and more

backbone are required in British policy, not only at Teheran but throughout Persia, which is difficult with the dual control that still exists, despite its condemnation by so many authorities.

(6). Consuls should be made to realise the importance of the trade and commerce of the British Empire, but this can hardly be hoped for without a stronger line of policy at Teheran, where a commercial attaché of experience and position would prove most useful to the Empire.

(7). Such commercial houses as desire to push trade with Persia should combine, so far as Southern Persia is concerned, and send out a common agent whose headquarters in winter and spring might be at Bander Abbas, and in summer and autumn at Kerman, depôts being opened under native sub-agents at Yezd, Bahramabad, Kerman, and Bam.

(8). The erection of suitable bonded warehouses, private or Government, at Bander Abbas, Bushire and Mohammerah, would enable stocks to be kept at these ports at a small cost and worked up-country as required. The erection of private bonded warehouses is provided for in the Règlement.

(9). At places where there are already well-established business houses, advantage might be taken of them to open up agencies, as long as it did not interfere with existing business arrangements.

(10). Lastly, it is strongly recommended that firms of standing and position in Persia should become members of some one or other of the Indian Chambers of Commerce, bodies that have done so much for the nterests of trade in India.

BIRTHS, DEATHS AND MARRIAGES.

The Registrar-General's report for 1905 shows that the decrease in the birth-rate which has been such a noticeable feature in the returns of recent years continues. The proportion was 27·2 per 1,000 of the total population of both sexes and ages, and this is the lowest rate recorded since civil registration was established. In 1876 the birth-rate attained in this country the highest point on record, namely, 36·3 per 1,000 living. Since then there has been decline, with hardly a break, the only exceptions being in 1891 and 1893 when there was slight recovery. But large as has been the diminution in the birth-rate, as a whole, the illegitimate birth-rate has decreased in larger degree. In 1870-2 as calculated on the unmarried and widowed female population, aged fifteen to forty-five years, it was 17·0 per 1,000; in 1905, it had fallen to 8·2.

If reference is made to the figures relating to international vital statistics, it will be found that whilst there has been a decrease in every European country, with the exceptions of Ireland, Austria, and Spain—the increase in Ireland being 2·30, in Austria 0·8, and in Spain 0·4—the decrease in the English birth-rate has been larger than in any other country save Belgium and France. In England, taking the 20 years 1880-82 and 1900-02, the proportion of legitimate births per 1,000 wives between the ages of 15-45 years was 17·7, in France, 19·7, and in Belgium 19·8, the decrease in the German Empire being only 8·4. But if reference is made to the Australasian colonies—no figures are given for other British colonies—it will be found that the decrease has been much more considerable even than in Belgium.

In Queensland, taking the same period, there has been a shrinkage of 23·2 per 1,000 wives, in South Australia 28·0, in New South Wales 30·6, and even in New Zealand 24·5. These are very remarkable figures, and suggest uneasy reflections. There would seem, as the Registrar-General says, to be some universal cause operating throughout civilised countries to account for the phenomenal decline in human vitality, and there is strong ground for the assumption that, in greater or lesser degree, the chief cause has been the deliberate restriction of child-bearing on the part of the people themselves. Even in countries like Australia, where one would have thought that large families would be welcomed, it seems that this influence is operating, and operating even in greater degree than in countries like England, where the means of subsistence are less easy to find.

Turning to marriages, the tables show that last year there was a slight increase as compared with the average of the ten years. The marriage-rate in 1893 was 14·7 per 1,000 living, during the next six years it steadily rose to a maximum of 16·5 in the year 1899, while from that date it fell continuously to 15·2 in the year 1904, and was, as above stated, 15·3 in the year under review. The figures show how great has been the diminution of the marriage of minors. In the years 1876-80 the number of husbands who were minors in a thousand marriages was 77·8, and of wives 217·0. In 1905 the figures were respectively 43·8 and 146·9. Since 1853, when no fewer than 304 out of every thousard men, and 439 out of every thousand women, who married signed the register by mark, the proportions of illiterate persons of both sexes have diminished almost continously, until in 1905 only 17 out of 1,000 bridegrooms, and 20 out of 1,000 brides, failed to sign their names.

The death-rate in the year under review was the lowest recorded since civil registration was established. It was 1·0 below that recorded in 1904, and was 2·0 per 1,000 below the mean rate in the ten years — 1894-1904. Infantile mortality shows a gratifying decrease, although it varies considerably in different counties, being highest in those of a suburban character, and lowest in those which are rural. The deaths of infants under one year of age were in the proportion of 128 per 1,000 births in the year under notice, as compared with 145 in the year immediately preceding, and 150 the mean proportion for the ten years —1895-1904. The proportion in 1905 is the lowest hitherto recorded. That urban life is not *per se* incompatible with a low rate of infantile mortality would appear from the fact that of the 217 chief towns of England and Wales, with populations exceeding 20,000 each, at the last census, thirty-two

were credited during 1905 with proportions of infantile mortality below 100 per thousand births. The towns in which low rates of infantile mortality were recorded may, generally speaking, be described as residential towns or suburbs, while those in which high rates prevailed are largely industrial in character. In no fewer than five of these towns, one out of every five children born did not survive the first year of life, whilst in Farnworth the average mortality reached the terrible rate of 228 per 1,000 births, which exceeds the total mortality in the first five years of life in England and Wales as a whole.

COMPULSORY EDUCATION ON THE CONTINENT.

In Italy and France the application of the law with regard to compulsory education is so disregarded that Rome, with a population of 507,000 inhabitants, has only 30,000 pupils in her primary schools, whereas she should send 70,000. About 20,000 of the pupils attend the public schools. In Paris, out of 225,000 children to whom the law should be applicable, 20,000 receive no instruction. This state of affairs led to the recent introduction of a motion in the French Chamber to fine parents who evade the law. It appears to be the practice in many French communities to "inscribe" children who are withdrawn from their classes to work in factory or field. Prussia is cited as enforcing the law for compulsory instruction. In Norway, Sweden, Denmark, and Switzerland all soldiers are said to know how to read and write. The law in Holland has been in force only since 1901, and Amsterdam shows the following increase in the percentage of children attending school:—In 1898, 36 per cent. of the population; in 1900, 44 per cent.; in 1901, 70 per cent. The compulsory law brought about a quick increase of 24 per cent. In a discussion in the Chamber for the adoption of a law for compulsory construction in Belgium, the statistics of 1904 bearing on the instruction of military recruits, were quoted as follows:—17·6 per cent. of almost absolutely ignorant recruits; 11·4 per cent. only had good primary instruction, while 71 per cent. had only the most elementary schooling. The following figures were also quoted concerning the proportion of illiteracy in two groups examined in 1906, of 100 men each. The first group had 30 completely illiterate, 24 able to write their names, and 46 able to read and write. The second group had 19 completely illiterate, 21 able to write their names, and 60 able to read and write. The school reports, between the years 1899 and 1902 were quoted to prove that only 14·6 per cent. of Belgian children received complete primary instruction, a large percentage leaving school with only rudimentary knowledge. The conclusion reached was that the number of children figuring in the scholar lists was no proof of the education of the masses, but rather of the sterility of a non-compulsory school system.

THE PANAMA HAT INDUSTRY.

One of the most important industries of the Republic of Colombia, is that of making palm hats, known as Panama hats, of which a quantity valued at £80,000 is exported annually. This industry follows in importance, those of coffee, gold, hides, tobacco, and rubber in the order named, and is carried on in the department of Cundinamarca, Tolima, Antioquia, and Santander, but mostly in the latter, where it is the breadwinner to more than one half its population. There are no regular factories, but the hats are hand-made by thousands of peasant women in almost as many households, and sold, or exchanged in the local stores for provisions or articles of clothing, the hat being in these regions a convenient medium of exchange; the housewife exchanging the product of her labour for so many pounds of flour, sugar, &c. According to the American Consul at Barranquilla, Panama hats are made with the fibres of a palm leaf, the tissues of which are scraped off, or combed in much the same way as hemp. The palm (*Carludovica palmata*) called locally "Jipijapa," is very small in appearance and grows in great quantities on the low and swampy lands of the Upper Magdalena. It grows wild, but is also cultivated, although to a limited extent, in the largest hat districts, the palm producing in a little over a year. The preparation of the fibre after the tissues have been combed off, consists of boiling the same in water containing salts and lemon juice for the effect of whitening and rounding its surface; this operation takes a few hours. The straw is then exposed to the night air for three consecutive nights, after which it is ready for use. The material employed in the making of a hat is marketed at the equivalent of from sevenpence halfpenny to one shilling and eight pence per hat according to the fineness and whiteness of the straw, the youngest leaves generally giving the best quality. It takes a woman four days to make an ordinary hat, eight days for a good one, and as much as fifteen days for the finest hat made in Colombia. The wages of a peasant woman employed in the making of a "jipijapa" hat are reckoned at fivepence a day, including her food which can be calculated at fivepence additional. The best hats exported from Colombia are those called "Suaza" made in the city of that name in the department of Cundinamarca. The next in order are "Antioqueños," made in the department of Antioquia. Then follow the ones made in the department of Santander, called respectively, "Zapatoca," "Barichara," "Bucaramanga," and "Giron," from the various cities in which they are made, and varying in quality and price in the order named. The "Zapatoca," although the most expensive, are supposed to be less durable than the other varieties. The best Suaza hat exported, costs, on the spot, about twenty shillings. and the cheapest, about four shillings; the Antioqueños are one degree cheaper, while the cheapest of all are those from the department of Santander, which range from two shillings to eight shillings according to quality. Indeed some Panama hats, made at the

rate of one a day, sell for less than two shillings, but these are made exclusively for home consumption and in no way exported. Hats are generally exported by the local merchants, mostly through the agency of a commission house at the port of shipment. In some cases foreign houses buy direct, whereas a few individuals take their own merchandise to the foreign country where it is marketed by them personally. The hats are packed in boxes weighing 132 pounds and containing from 40 to 50 dozens each. As above explained, Panama hats are made in a most primitive way. Accordingly, any machinery which could increase the output materially and reduce at the same time the number of workpeople would be a great benefit to the industry, which is very attractive since it needs but a small capital, and promises good returns to any one engaging in it systematically.

THE UNITED STATES LEATHER TRADE.

There has been a very rapid growth in the American leather trade during the last ten years, according to the United States Bureau of Statistics. The leather industry in that country contributed £30,000,000 to the foreign commerce in 1906, against £11,000,000 in 1896. These figures include the imports and exports of leather and its manufactures, and imports and exports of hides and skins. The value of hides and skins imported in 1906 was about £17,000,000, while in 1896 the value was £4,000,000. Over £9,000,000 worth of leather and its manufactures were exported in 1906, against £3,800,000 in 1896, while the value of these articles imported in 1906 amounted to £3,600,000. The value of hides and skins exported in 1906 was nearly £400,000. Of the £9,000,000 worth of leather and its manufactures exported, £1,900,000 represented boots and shoes, £5,000,000 upper leather, £1,600,000 sole leather, and the remainder, £400,000, harness and saddlery. The United Kingdom took nearly £400,000 worth of boots and shoes, £2,700,000 worth of upper leather, and £1,300,000 worth of sole leather in 1906, against £50,000, £1,500,000, and £1,070,000 respectively, in 1896. The other countries which took large quantities of American boots and shoes were Canada, West Indies (exclusive of Porto Rico), and Mexico, while Belgium, France, Germany, the Netherlands, South America, Australia, and various parts of Asia and Oceana, all took greater or less quantities of boots and shoes, and moreover, many of these countries are good customers for other classes of leather. Of hides, Argentina sent to the United States in 1906, £1,000 worth, India over £400,000, Canada £475,000, France £400,000, and Mexico more than £200,000. The imports of goat skins amounted to £6,500,000, of which India contributed nearly £2,200,000 worth, Mexico £500,000, France £400,000, China £625,000, and, in addition, the United Kingdom, Brazil, Argentine, Arabia and Russia each sent more than £200,000 worth.

ARTS AND CRAFTS.

Apprenticeship and the Artistic Crafts.—There has been a good deal of talk of late about the decay of apprenticeship. Until recently the subject was more often approached from the purely economic standpoint, but we are hearing a considerable amount about it now from the point of view of its effect on the artistic crafts. Some time back it was taken more or less for granted in some quarters that the apprenticeship system was rather in the nature of a survival, that sub-division of labour was bound to bring in its train the abolition of the old method of training, and that, after all, it probably did not much matter. The fallacy of this attitude from an economic point of view has been abundantly proved, and the breakdown of the apprenticeship system is now looked upon as a very serious difficulty, largely responsible for a heavy proportion of unemployment and unemployableness in later life. From the side of art and craftsmanship the matter stands, of course, in a slightly different light. The question is not so much how a man can best fit himself to earn his living, as how he can best learn to be a master of his trade. Some time back it would have been said that all that was required was technical education, that a lad could and would learn at the art school or the technical institute (which, by the way, he very often attended only two or three evenings a week) far more and far better than in the workshop, where his teaching was most likely unsystematic and had to be picked up rather casually in the course of the day's work from fellow workmen, probably uneducated and possibly unintelligent. Few went to the length of wishing apprenticeship to die out, or to see workshop training supplanted by school teaching, but there seemed to be a rather easy kind of optimism afloat which assumed that it did not much matter anyway, and that somehow things would come all right. Of course, the apprenticeship system is not dead. It still goes on in various highly skilled trades, and in others, where it is not the custom for the boys to be indentured, they go first as learners, with a sort of general understanding that they will learn their trade in so many years and at the end of that time will be paid as skilled workmen. This is a custom which may work out at much the same thing as apprenticeship, but at times it certainly does not. Miss King, in her interesting report on the silver and jewellery trades in London, tells us that "a silversmith's term of apprenticeship is usually for seven years," though some of the subsidiary processses seem to be carried on by people who are not formally apprenticed. Still, it is not nowadays by any means the rule for all boys who go into skilled trades to be indentured.

By this time the general faith in technical schools as places where students would, better than in the workshop, learn their trade, has broken down. Many of the schools are doing excellent work in the way of supplementing the training which the lads get in the

shop during the day, and of giving them an outlook which is not merely that of "the trade;" but the schools, as a whole, do not and cannot supply the place of workshop training, and in some of them the standard of technique is deplorably low.

The School of Art Wood-carving.—It is, therefore, all the more refreshing to read the Report of the School of Art Wood-carving for the past year. Wood-carving is a craft which lends itself better than many others to school instruction. In teaching it, it is far more possible to reproduce the conditions of actual trade work than in many crafts which require more elaborate plant and a greater range of methods. What is wanted is competent instructors and a system of management which aims at turning out capable carvers rather than artists with a taste for carving. This appears to be the object which the school keeps in view—and the results are decidedly satisfactory. Not only is there a good attendance of teachers and trade carvers at the evening classes, but the male students who take the full course are turned out as fully equipped and practical workmen, and some of them, at any rate, go straight from the school into trade workshops where they "have received from the start the wages of trained carvers, the school thus taking the place of apprenticeship." The West Ham Borough Council and the Kent Education Committee have taken advantage of the training afforded by the school and send some of their most promising students to profit by the teaching and to be fitted to start in life as competent workmen.

Even allowing for the comparative suitability of wood-carving to school instruction, such a report as that issued by the School of Art Wood-carving is encouraging. We hear on all sides of promising students who can get no work to do, and of manufacturers and others who will have nothing to do with students who have been trained in art schools. A report like this raises the question whether the difficulty has not largely arisen from a mistake in the aim of the teaching. Had the powers that be set themselves to training workmen who should add to a thorough knowledge of technique a certain amount of appreciation of what is best in workmanship and design, they might perhaps have done really more for the encouragement of art than by turning out art students who have an acquaintance by no means thorough with one or two artistic crafts.

Arts and Crafts and Costume.—Not so very long ago the bare suggestion of an exhibition of Arts and Crafts applied to costume would have been scouted as ridiculous. Now the Lyceum Club is opening its doors to a show of such work executed by its members. It is perhaps fitting that such an innovation should be introduced at an energetic ladies' club, and, though the collection of objects is not very large, it is enough to show the kind of way in which women working in the artistic crafts cater for the wants of their sisters. As might have been expected, it is the work of the jewellers which predominates, and though one could wish for a little more control over the material in some of the enamel, the work as a whole is characterised by the judicious introduction of transparent colour, both in the form of enamel and of jewels cut *en cabochon*. The workmanship of the different exhibitors naturally varies, and there is good, bad, and indifferent, but the level on the whole is fairly high, and the work of several contributors, notably of Mrs. Hadaway and Miss Woodward, is thorough, tasteful, and quite sufficiently original.

Passing over such items as fans, bags, purses, and the like, which are, perhaps, hardly to be classed altogether as "costume," we come to the arts more intimately connected with dress. Leather work has been pressed into service, not in the form of artistic boots and shoes, but as supplying some characteristically simple plaited leather belts. There is rather less embroidery than one would naturally have expected to find, perhaps because embroidery as a trade is as a rule so badly paid; but the front and sleeves shown by Mrs. Reynolds-Stephens are very satisfactory. They are not, however, the kind of work which could ever be very much done in a commercial kind of way, as the labour involved in their execution would be greater than the ordinary buyer, ignorant of embroidery methods, would probably be willing to pay for. Another less interesting and far less finely executed piece of trimming contributed to the exhibition, though it is in no way remarkable, is on lines which are nearer to the kind of work for which there should be a market. After all, coarse work has its uses, especially when designed for clothes which will presumably soon be out of fashion.

The dress designed by Mrs. George Turnbull gives food for reflection. As a dress, perhaps, it hardly comes within the scope of these notes, though he would a bold man who suggested that dressmaking was not an art, and in one sense at least it is certainly a craft. Any way, as embroidery, it is well within our province. The garment is made of some thin grey material, and is decorated with padded tulips, of a yellowish pink with green leaves cut out of velvet (painted, stencilled, or printed, it is difficult to say which) and applied with a thick gold or silver cord at the edge. The result if not altogether happy, it is at least suggestive. It is not difficult to imagine a dress in some fairly neutral tint, which would make a good background, ornamented with *appliqué* embroidery in some material not too unlike the ground stuff in weight, though differing from it in texture which might be not only pleasing in design, but quite beautiful in colour. By the way, padded *appliqué* hardly seems suitable for a dress whether from the point of view of elegance or of comfort. The level of work shown at the Lyceum Club is quite good, and there are among the exhibits things which are both fresh and worthy of notice, but the main interest of the show lies perhaps in the connecting thread of purpose which draws the objects together.

GENERAL NOTES.

TURIN PHOTOGRAPHIC EXHIBITION.—An International Exhibition of Artistic and Scientific Photography will be held at Turin, in May, 1907. There will be two divisions, one for amateurs, and the other for professional photographers. Artistic photography will include figure, landscape, marine, flower and animal pictures. Scientific photography will consist of micro-photography and astronomical photography. Applications for space will be received until April 30th, and the objects themselves until May 15th. Application can be made to the office of "La Fografia Artistica," Rue Accademia Albertina No. 1, Turin.

BLACK CURRANT MITE.—The Board of Agriculture and Fisheries announce that a new edition of their leaflet on the "Black Currant Mite" has been published, in which information on the treatment of this pest with lime and sulphur has been incorporated. Fruit-growers whose bushes have been attacked with the mite are advised to experiment with this process. Copies of the leaflet may be obtained gratis and post free on application to the Secretary of the Board of Agriculture and Fisheries, 4, Whitehall-place, London, S.W. Letters so addressed need not be stamped.

THE GERMAN CEMENT TRADE.—The German cement industry is looking back upon the year 1906 as an extremely favourable one; the business was throughout more profitable in every respect than during a number of previous years. The joint stock capital of thirty of the largest works, representing approximately £4,500,000, yielded from £460,000 to £500,000 interest, or, 10·7 to 11·4 per cent. In the year 1905, the dividend amounted to about 8·5 per cent., calculated on a capital of £4,240,000. Dividends of the companies in question, in the last eight years, 1899-1906, were as follows:—14·3, 11·25, 5·24, 4·41, 5·14, 6·58, 8·5, and 10·7 to 18·4 per cent. respectively. According to the American Consul-General at Hamburg, the reason for this favourable development in the industry was chiefly the building activity throughout the country in 1906. Although during 1904 and 1905, a similar activity prevailed, prices suffered in those years from the consequences of over-production. Notwithstanding the fact that in 1905 such an over-production did not make itself felt so much as in the preceding year, the production during the year 1906, although a number of new works were started, did not in general exceed, in a marked degree, the demand. This supposition is confirmed by the statistics of the import of cement during last year. In 1905 exceptionally large quantities were imported, but in 1906 the imports increased further, as the following statistics prove. During the eleven months from January to November of the last six years, 1901-1906, inclusive, the quantities of Roman and Portland cement and hydraulic lime imported into Germany were as follows:—In 1901, 84,185 tons; in 1902, 51,059; 1903, 48,902; 1904, 57,325; 1905, 140,271; and in 1906, 221,449 tons. By far the largest quantities were imported from Belgium, chiefly into Western Germany. The consequence was that the Rhenish Westphalian Cement Syndicate, although it was itself in full activity throughout the year resorted to energetic measures by opening sale rooms in Cleve and reducing its prices to beat down foreign competition. In other respects, however, prices increased slowly but steadily. This favourable tendency was increased by the fact that the feeling among the various German cement syndicates was a more peaceable one than in the preceding years; furthermore, because enormous quantities of cement were exported, in which movement the San Francisco and Valparaiso earthquakes were important factors.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday Evenings, at 8 o'clock:—

APRIL 17.—"Aerial Navigation." By MAJOR B. F. S. BADEN-POWELL. SIR BENJAMIN BAKER, K.C.B., K.C.M.G., F.R.S., will preside.

APRIL 24.—"The Cultivation of India Rubber." By HERBERT WRIGHT, Controller of the Government Experimental Station, Ceylon. LIEUT.-COL. DAVID PRAIN, C.I.E., F.R.S., will preside.

MAY 1.—"The Defence of the Sea Coast from Erosion." By ALFRED EDWARD CAREY, M.Inst. C.E.

MAY 8. — "The Production of Coke and its Application in Domestic Fires." By PAUL SCHLICHT. CORBET WOODALL will preside.

MAY 15.—"Trypanosomiasis or Sleeping Sickness." By HERBERT W. G. MACLEOD, M.D., B.Sc.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

MAY 2.—"The Applicability to Indian Rivers of the Italian System of Dealing with Silt." By SIR EDWARD CHARLES BUCK, K.C.S.I., LL.D., late Secretary to the Government of India, Revenue and Agricultural Department.

MAY 30.—"Irrigation Colonies in India." By LAURENCE ROBERTSON, I.C.S., Under Secretary to the Government of India, Revenue Department.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

APRIL 23.—"Social and Economic Conditions in Australia." By the HON. JOHN WINTHROP HACKETT, LL.D.

APPLIED ART SECTION.

Tuesday evenings, at 8 o'clock:—

APRIL 16.—"Joinery and Furniture Making." By A. ROMNEY GREEN. HALSEY RICARDO will preside.

APRIL 30.—"Lustre Pottery." By WILLIAM BURTON. J. C. WEDGWOOD, M.P., will preside.

MAY 28.—"Sheffield Plate and Electro-plate." By SHERARD COWPER-COLES.

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

PROF. HERBERT JACKSON, F.I.C., F.C.S , "Detergents and Bleaching Agents used in Laundry Work." Three Lectures.

LECTURE I.—APRIL 15.—Water in its relation to laundry work—Hardness of water and softening agents—Treatment of boilers showing pitting—Soaps and their composition—Easy methods of examining and valuing soaps—Behaviour of soaps with water—Hydrolysis of soaps.

LECTURE II.—APRIL 22.—The alkalies used in laundry work — Their relative values and useful strengths—Bleaching agents—their composition and properties—Methods of applying bleaching agents—Their comparative value—Dangers in the use of bleaches—Methods of valuing bleaches.

LECTURE III.—APRIL 29.—The problem of washing—Textile fabrics: easy methods of distinguishing between them chemically and by the microscope—Shrinkage of woollen goods—Behaviour of various fabrics with detergents and bleaching agents—Influence of acids, alkalies, &c., on the individual fibres—Precautions to be observed.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, APRIL 15 SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Prof. Herbert Jackson, "Detergents and Bleaching Agents used in Laundry Work." (Lecture I.)

TUESDAY, APRIL 16. SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Applied Art Section.) Mr A. Romney Green, "Joinery and Furniture Making."

Asiatic, 22, Albemarle-street, W., 3 p.m.

Royal Institution, Albemarle-street, W, 3 p.m. Professor G. H. Bryan, "Wings and Aeroplanes." (Lecture II.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1 Mr. Percy Allan, "The Pyrmont Bridge" 2. Mr. W. H. B. Saville, "Swing Bridge over the River Avon at Bristol."

Statistical, 9, Adelphi-terrace, W.C., 5 p.m. Mr. Albert E. Lark, "The Herring Fishery of Great Yarmouth."

Pathological, 20, Hanover-square, W., 8½ p.m.

Photographic, 66, Russell-square, W.C., 8 p.m. Mr. A. Marshall, "Some Dutch Pictures"

Anthropological, 3, Hanover-square, W., 8½ p.m.

Horticultural, Vincent-square, Westminster, S.W, 3 p.m. Mr. R. H Curtis, "Rainfall in its Relation to Horticulture."

Pharmaceutical, 17, Bloomsbury-square, W.C., 8 p.m.

WEDNESDAY, APRIL 17. SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Major B. F. S. Baden-Powell, "Aerial Navigation."

Meteorological, 25, Great George-street, S.W., 7½ p.m. 1. Mr. R. L. Holmes, "Phenomenal Rainfall in Suva, Fiji, August 8th, 1906." 2. Mr. R. Strachan, "Temperature around the British Islands in relation to the Gulf Stream." 3. Mr. L. C. W. Bonacina, "Weather regarded as a Function of Climate."

Geological, Burlington-house, W., 8 p m.

Microscopical, 20, Hanover-square, W., 8 p.m. 1. Mr. E. M. Nelson, "The Podura Scale." 2. Exhibition of Slides of Foraminifera, by Mr. A. Earland.

United Service Institution, Whitehall, S.W., 3 p.m. Mr. C. Bright, "Submarine Telegraphy."

British Archæological Association, 32, Sackville-street, W., 8 p.m.

THURSDAY, APRIL 18 Royal, Burlington-house, W., 4½ p m.

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Mr. J. C. Shenstone, "The Œcologic Functions of Stolons and Cleistogamous Flowers." 2. Mr. A. O. Walker, "The Œcologic Aspect of Constitutional Variation in Fruit Culture" 3 Mr. Hugh Scott, "An Aberrant Form of Coccidæ." 4. Professor W. B. Bottomley, "Some Results of Inoculation of Leguminous Plants." Exhibitions:—1. Dr. George Henderson—Nepal Barley and other Cereals cultivated at high latitudes in Tibet. 2. Mr. J. A. Weale — Photographs of Sections of Woods. 3. Mr. J. Saunders—Lantern Slides of "Witches' Brooms."

Chemical, Burlington-house, W., 8½ p m. 1. Sir W. H. Perkin, "The Magnetic Rotation of Hexatriene, CH_2:CH.CH:CH.CH:CH_2, and its Relationship to Benzene and other Aromatic Compounds, also its Refractive Power." 2. Messrs. M. O. Forster and H. E. Fierz, "Aromatic Azoimides. Part I. p-Hydroxyphenylazoimide." 3. Mr. O. Masson, "The Action of Hydrogen Peroxide on Potassium Cyanide." 4. Mr. S. Ruhemann, "The Action of Ethyl Oxalate on Thioacetanilide and its Homologues." 5. Messrs. A. McKenzie and H. B. Thompson, "Measurements of the Velocities of Saponification of the l-Menthyl and l-Bornyl Esters of the Stereoisomeric Mandelic Acids." 6. Messrs. A. G. Perkin and W. P. Bloxam, "Indican." (Preliminary notice.) 7. Mr. P. C. Ray, "Cupric Nitrite." 8. Mr. M. Barrowcliff, "The Constituents of the Essential Oil of American Pennyroyal. Occurrence of a Dextro-Menthone." 9. Messrs. T. E. Gardner and W. H. Perkin, "The Action of Tribromopropane on the Sodium Derivative of Ethyl Acetoacetate."

Royal Institution, Albemarle-street, W., 3 p m. Professor Henry A. Miers, "The Birth and Affinities of Crystals." (Lecture II.)

Optical, 20, Hanover-square, W., 8 p.m. Presidential address by Mr. Walter Rosenhain, "Physical and Engineering Uses of the Microscope."

Electrical Engineers (at the HOUSE OF THE SOCIETY OF ARTS), John-street, Adelphi, W.C., 8 p m. Mr. A. Schwartz, "Flexibles: with Notes on the Testing of Rubber."

Historical, Lecture Hall, Field-court, Gray's-inn, W.C., 5 p.m.

Numismatic, 22, Albemarle-street, W., 7 p.m.

FRIDAY, APRIL 19 ..Royal Institution, Albemarle-street, W., 9 p.m. Prof C. F. Sherrington, "Nerve as a Master of Muscle."

North-East Coast Institute of Engineers and Shipbuilders, Westgate-road, Newcastle-on-Tyne, 7½ p.m. Mr. A. E. Long, "Trim Curves."

Quekett Microscopical Club, 20, Hanover-square, W., 8 p.m.

Women Journalists (at the HOUSE OF THE SOCIETY OF ARTS), John-street, Adelphi, W.C., 8½ p.m. Mr. Alexander Kenealy, "Illustrated Journalism."

SATURDAY, APRIL 20...Royal Institution, Albemarle-street, 3 p.m. Prof. Sylvanus P. Thompson, "Studies in Magnetism." (Lecture II.)

Journal of the Society of Arts.

No. 2,839. VOL. LV.

FRIDAY, APRIL 19, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, APRIL 22, 8 p.m. (Cantor Lecture.) PROF. HERBERT JACKSON, "Detergents and Bleaching Agents used in Laundry Work." (Lecture II.)

TUESDAY, APRIL 23, 4.30 p.m. HON. JOHN WINTHROP HACKETT, LL.D., "Social and Economic Conditions in Australia."

WEDNESDAY, APRIL 24, 8 p.m. (Ordinary Meeting.) HERBERT WRIGHT, "The Cultivation of India Rubber."

*** A Collection of Samples of India Rubber, principally Colonial, will be exhibited at the Meeting, and will remain on view for a few subsequent days.

Further details of the Society's meetings will be found at the end of this number.

CANTOR LECTURES.

On Monday evening, 15th inst., PROF. HERBERT JACKSON, F.I.C., F.C.S., delivered the first lecture of his course, on "Detergents and Bleaching Agents used in Laundry Work."

The lectures will be published in the *Journal* during the summer recess.

APPLIED ART SECTION.

Tuesday evening, April 16th, HALSEY RICARDO in the chair. The paper read was "Joinery and Furniture Making," by A. ROMNEY GREEN.

The paper and report of the discussion will be printed in a future number of the *Journal*.

MULREADY PRIZE.

The Council of the Society of Arts are prepared to offer, under the terms of the Mulready Trust, a Gold Medal, or a prize of £20, for competition amongst students of the Schools of Art of the United Kingdom, at the Annual National Competition to be held in 1908.

The prize is offered to the student who obtains the highest awards in the following subjects:—

(*a*.) A finished drawing of imperial size from the nude living model.

(*b*.) A set of time studies on a small scale, from the nude living model, executed in a short time, of varied shortly sustained poses (mounted on not more than two imperial size mounts).

(*c*.) A set of studies of hands and feet from the living model (mounted on not more than two imperial size mounts).

(*d*.) Drawing from the life, including memory life drawing done at the Examination in May, 1908.

No student will be eligible for the award who does not pass in the Examination (*d*) in drawing from the life, and who does not obtain an award for (*a*) the finished drawing of imperial size from the nude living model. The other two subjects are optional.

The works must have been executed between 1st April, 1907, and 31st March, 1908.

The recipient of a prize awarded under this trust in 1892, 1893, 1896, or 1903, cannot compete again.

The drawings, &c., are to be submitted, with other school works, in the usual manner to the Board of Education, South Kensington, in April, 1908. Each competing drawing must be marked "In Competition for the Mulready Prize," *in addition* to being labelled according to the Regulations of the Board of Education.

PROCEEDINGS OF THE SOCIETY.

SEVENTEENTH ORDINARY MEETING.

Wednesday, April 17, 1907; SIR BENJAMIN BAKER, K.C.B., K.C.M.G., F.R.S., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Felberman, Louis, Bladen-lodge, Bolton-gardens South, S.W.
Foucar, Alexandre Ferdinand Emile, Beaulieu, St. John's-park, Blackheath.
Shaw, Mrs. G. Bernard, 10, Adelphi-terrace, W.C.

The following candidates were balloted for and duly elected members of the Society:—

Aird, Mrs., 22, Eaton-square, S.W.
Charlier, Edgard, 19, Lerchenfeldstrasse, Munich, Bavaria, Germany.
Ghosh, Henry A., 9, Middle-road, Entally, Calcutta, India.
Griffin, John R., Kemble-street, Kingsway, W.C.
Khan, M. Habib ur Rahman, Habibganj, District Aligarh, India.
Mukharji, Sivnarayan, Uttarpara, near Calcutta, India.
Percival, Professor Hugh Melville, M.A., 14, Park-street, Calcutta, India.
Ransome, Ernest L., Westervelt-avenue, Tompkinville, Staten Island, and 11, Broadway, New York City, U.S.A.
Reid, Hugh, D.L., J.P., M.Inst.C.E., Belmont, Springburn, Glasgow.
Reitlinger, Albert, 33, Fitzjohn's-avenue, N.W.
Wood, E. Escott, Hurricane-house, Brymbo, North Wales.
Woolner, A. C., M.A., Punjab University, Lahore, India.

The CHAIRMAN, introducing the reader of the paper, said the members of the Society had, on a former occasion, the advantage of hearing Major Baden-Powell read a paper on the subject of his present paper. Anyone interested in the subject knew that the author was one of the earlier experimenters and authorities on it. The theatre of the Society of Arts was the only one in London, he believed, which welcomed discussion on any subject of national or public interest; and as the subject of the paper was one which was exercising a great deal of public attention at the present time, the Society was indebted to the author for again drawing attention to it. He hoped the discussion would be a good one, but personally he could only contribute to it incidentally, as he was not an expert on the question, his career having been in the opposite direction, of preventing structures designed and constructed by himself, such as bridges and roofs, from becoming flying machines.

The paper read was—

AERIAL NAVIGATION.

BY MAJOR B. F. S. BADEN-POWELL.

INTRODUCTION.

In the following paper I propose to refer briefly to three special points. I say "briefly," because each of them forms a subject on which volumes might be written.

First, I intend to indicate how vastly important the subject of aeronautics may become in the future, and that this future may not be so very distant. Secondly, I would refer to some of the general principles of aerodynamics, and thirdly will relate such facts as I have been able to ascertain as regards aerial machines which have, during the last few months, undergone successful trials.

I am one of those who believe that we are just about to enter an era of great change in human life. Various inventions have been introduced at different periods which have had a great influence on the progress of the civilised world; the steam-engine, the railway, the telegraph, the steamship, and many others. But it would now seem as if all these were to be outdone by an innovation still more affecting our daily life. Progress in invention is nowadays so rapid (as an instance take the introduction of the motor-car) that but a very few years are required to introduce an absolute novelty into everyday use.

Just recently, during the last two or three years, immense progress has been made in steps towards the practical navigation of the air. I will not now refer to balloons, since although propelled, gas-filled airships have lately been so improved as to be adopted as practical vessels of war, yet it looks decidedly as if these must go under and become quite obsolete the moment anything in the way of a gasless machine proves practicable.

It will perhaps hardly be necessary to define what I mean by a gasless flying machine. Everyone nowadays has a general idea of the aeroplane or propelled kite method of transportation through the air.

RECENT PROGRESS.

Ten or fifteen years ago authorities writing on the subject stated that if only it were possible to make engines so light as to weigh but 10 lbs. per horse-power there would be no difficulty in constructing a flying machine. A few years after, petrol engines were made of such a weight. To-day they are made, and on the

market, weighing no more than 2½ lbs. per horse-power!

Sceptics used to say that it would be impossible to raise a large apparatus off the ground by engines and propellers. To-day this has been accomplished, not once but on many different occasions. They also urged that, once in the air, it would be impossible to balance the machine in steady flight. Now, although this has proved somewhat of a stumbling block, we hear of men maintaining themselves for half an hour at a time in mid air while being propelled along at a great speed. Many have declared the landing would be a difficulty, but, even without considering these recent flights, we know that thousands of glides have been made with man-carrying gliding machines that have almost always ended satisfactorily.

So it seems as if all arguments against the attainment of practical flight could be controverted, and as so much experimenting is now going on, there seems a great probability that not many years will elapse before we are able to fly hither and thither where we will.

Characteristics.

Such a machine would probably travel very fast indeed; there are no bumpy roads; no children, dogs, or chickens to get in the way; no abrupt turnings or sudden apparitions of crossing vehicles to be considered; the air is nearly frictionless; the view for several hundred yards is nearly always clear; if one can go up or down as well as to right or left, obstacles and other machines are more easily steered clear of than is the case with wheeled vehicles or marine vessels. Wear and tear of machines skimming through the air is likely to be nothing as compared to means of travel by land or by sea.

It will not be necessary here to speculate at any length as to the uses of such machines. In war they will evidently be of supreme importance. If, as appears probable, they can be constructed at less cost than a motor-car, they should soon come in for everyday travel. Though it may not, at first, be easy to transport heavy goods by this method, yet mails and light articles might be dispatched. Seeing that one can go straight from door to door, independent of roads or bridges, the rate of travel is again increased. But perhaps the most remarkable innovation—one which will call for the serious consideration of our legislators, is the ability to pass all barriers, crossing not only walls and fences into private property, but also international frontiers.

But now let us get to some more practical aspects of the question. We want to know more about what the airship of the future is to be like. Only a few years ago, with no experience to go upon, no one could say much authoritatively. But now, although there is still very much to learn, and we are but scratching the surface of the subject, many facts have been ascertained which throw considerable light on the question.

Aerodynamics.

It is necessary for those who would design an airship, and many minds are now being concentrated on that objective, to make some study of the principles of aerodynamics, and though it would be quite impossible to go at all thoroughly into the subject in a paper such as this, my object is to touch upon a few main points, and I hope to elicit the opinions of those who have made study in these lines, or who can suggest a scientific explanation of some of those points which seem at present rather obscure.

The science of aerodynamics, that is to say the study of the reaction of the air on bodies moving through it, has only recently been seriously taken up. As I have pointed out elsewhere, many text-books of to-day in referring to wind pressures, quote, word for word, a table concocted by a practically unknown authority no less than 150 years ago! Yet recent careful observations tend to show that this table is quite misleading. I need not here relate the various experiments which have been made to determine the pressure of the wind at a given velocity, as I have summarised them in a recent article in "Knowledge," but I will merely state that it is now pretty well decided that the pressure (in lbs. per square foot) exerted on a surface moving against the air is somewhere about ·003 times the square of the velocity in miles per hour. In the table referred to, Rouse made the figure ·005. This subject, as applied to wind pressures, is one on which there are few better authorities than our worthy chairman of to-night.

It has been proved that the size and shape of the body may make some difference in the relative pressure per square foot, as may the velocity when considering very high speeds. What we are now considering is the pressure developed on a plane surface moving at right angles. But when this surface is inclined, other complicated calculations come in.

In considering the action of the air on

plane surfaces at an inclination, the student of aeronautics must again be warned not to trust what he may see in older books treating of the matter. Newton contended that the pressure on such a plane varies as the square of the sine of its inclination, or to put it in less mathematical language, as the plane becomes more upright the pressure increases as the square of the angle. Langley, in his elaborate experiments, as well as others, have proved this to be quite erroneous, so that when a plane is inclined at a very small angle, instead of the pressure rapidly becoming almost nil, it remains very considerable. Thus, at an inclination of 5°, according to Newton's theory, the vertical upward pressure would be but ·0076 of that on the plane placed normally, while Langley found it to be ·15, or no less than twenty times as great.

Chanute, summarising the conclusions of many experimenters, has shown that the formula of Duchemin

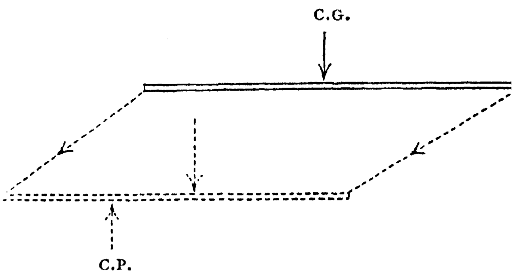
$$P = P^1 \frac{2 \sin \alpha}{1 + \sin^2 \alpha}$$

is probably about correct, as the proportion between P, the pressure on an inclined surface, and P^1, that on the surface if placed perpendicular, α being the angle of inclination of the surface.

But, even with such formulæ before us, it is by no means easy to calculate what speed must be given to an aeroplane in order to support a given weight. Theoretically this can be done straight off but in practice it is different.

Let us start by taking a flat piece of paper. If this be held horizontally and dropped, it ought according to theory to fall directly downwards at a given rate. Now see what happens. It is evident that, drop it as carefully as we like, it will always start swaying about and moving from side to side till it falls over. In looking for a cause for this, we find a fact, which has been investigated by Langley and others, that with an inclined surface the centre of pressure is not in the centre of the surface, but towards its front edge, and that the more the surface is inclined, the further, up to a certain point, does this centre advance. This is known as Joëssel's law, his formula being $C = (0{\cdot}2 + 0{\cdot}3 \sin \alpha)\,L$, when $C =$ centre of pressure, L the length from front to rear, and α the angle of inclination.

This being the case, it is easy to see that directly our sheet of paper while falling moves towards one side or other (and as its edge offers so little resistance it is very liable to do so), then instead of meeting the air at right angles, as in falling perpendicularly, it meets it at an angle, thus :—



But by Joëssel's law the pressure will then advance towards the front, instead of being in the centre of the surface, and this must cause the advancing edge of the paper to turn upwards. When the paper is thus tilted the centre of pressure moves back, and the paper will tend to resume its former position. So we obtain a swinging pendulum action which increases more and more.

SPINNERS.

This brings us to an interesting little experiment which might possibly be taken advantage of in aerial apparatus.

If we take an oblong piece of paper, narrow in proportion to its length, this action becomes so intense that the paper when dropped will spin rapidly about its longer axis. On trying different shaped pieces of paper, we soon find several facts. The narrower the paper in proportion to its length, the faster it spins. We also notice that such an arrangement falls comparatively slowly to the ground. But we also may note that it always falls at a fixed angle. The narrower the paper the steeper the angle of fall—about 45° An arrangement such as this has been suggested as a parachute or safety appliance in a flying machine, both by Mr. Dunne in this country and by Herr Kœppen in Germany. This, though an interesting subject on which much might be said, is but a digression.

BALANCE.

Now if we want the paper to fall steadily it will be found that, unless we suspend a heavy weight below it, it is necessary to let it fall sideways—by arranging the centre of gravity towards the leading edge. Then the paper will fall in an inclined direction as before, but if the weight be on the centre of pressure as shifted it will fall steadily at the given inclination. However, this shifting of the centre of pressure is, as we have seen

dependent on the angle of inclination. Taken as a general rule, we find experimentally that if the centre of gravity be at a point just about one-third (but more correctly ·3) of the width of the paper the latter will glide down fairly stably. Working this out by Joëssel's law α should equal nearly 30°. Here is a piece of paper to which a string is attached exactly one-third across from the edge. It is so weighted that when suspended by this string it hangs just horizontally; on starting this with a slight push forward it will glide nicely through the air.

But this gliding is not well explained. One might have expected this paper to fall down at an angle of 30°, whereas what it does is, after falling a certain distance and getting up a certain speed, it goes horizontally and even rises in the air. This, again, is due to the pressure coming gradually more to the front as the speed increases. And I have here another model which may seem at first to show some inexplicable effects. It is usual to consider an aeroplane as a plane surface driven against the air at a certain definite inclination, which results in a certain pressure on the under surface. In fact, it is considered to be precisely the same action as that of the wind on a kite. But now in this case you may observe that there are three planes one behind others, each of which is set at a small *negative* angle —that is to say each plane points slightly downwards. Yet, on pushing this forward, it will be seen to travel horizontally and even to rise. This would seem to imply that it is not necessary for the air to impinge upon the under surface, but that some action is caused on the top of the plane.

Another point, which we find by experiment, is that narrow planes are more efficient than wide ones.

Here I have a paper plane, with centre keel to keep it straight, and suitably ballasted in front. You will observe that, when this is projected forward, it will first rise, owing to the shifting forward of the centre of effort. Then it will fall back again, and turn again, till it falls headlong to the ground. Now take an exactly similar paper, similarly weighted, and cut it into a number of transverse slips—so as to present a series of narrow planes—and you see it glides fairly steadily.

Back Suction.

In considering the pressure on a thin plane surface one is apt to ignore what goes on behind it. In addition to the actual pressure on the front side there must be a negative or suction action on the back. Here is an experiment which is often considered somewhat mysterious. A rigid plane surface has a light movable surface hinged to the front edge of its back or upper side. When a current of air is directed on to the face of this it will be seen that the thin piece of paper, which should be screened under the lee of the rigid piece, rises up. This action, it seems to me, may be explained as follows: — Between the two layers of paper exists a film of air at ordinary pressure. When the current of air passes over the front edge, it draws along with it some of the air above the thin paper. This portion being deprived of its full complement of air, a partial vacuum is formed, and the thin paper, with vacuum above and ordinary pressure below, must rise up.

Another important fact in aerodynamics, unknown till Langley demonstrated it some fifteen years ago, is that a plane surface propelled horizontally through the air will fall more slowly than one falling vertically without progressing. This fact may sound peculiar, but it is easily explained. With the falling plane, the air is pressed away from the under surface and has to find its way round to fill the vacuum which would otherwise be formed above. This takes time, but before the requisite time has elapsed, the plane has moved forward and has a fresh lot of air to deal with. Langley only experimented on speeds up to about 45 miles an hour, and it would be very instructive to know what the results would be at higher speeds. This is a very important law as affecting aerial machines—for it implies that by travelling very quickly we can obtain great lifting power. Langley compared the action to that of a skater who proceeds rapidly across thin ice, ordinarily unable to bear his weight, but which has not time to break under him.

Curved Surfaces.

Lilienthal first pointed out, or rather laid stress on the fact, that slightly curved surfaces, concave underneath, were more efficient as sustainers than flat planes. Notwithstanding the theories he advanced, the exact action of the air on these concave surfaces is not well understood. It has also been shown that when the concavity is pronounced near the front edge, that is whilst the section of the surface is thus, a revolving eddy is formed under the front part, which seems to assist the

whole to progress forward. Hargraves stuck small feathers on the under surface of such a body, and these when exposed to a strong current of air, were blown towards the front.

But again we have to look to the upper side as well as the lower, and here we find a very odd effect. The air striking, or struck by, such a curved convex surface is thrown off upwardly, so that a partial vacuum is formed. This is well instanced by a little toy consisting of a light ball, against which a jet of air is blown. The ball remains suspended at a certain distance above the orifice of the jet. But now if the jet is inclined, to say as much as 60° with the horizon, the ball still remains suspended and does not fall to the ground. This is not easy of explanation, but must be due to some such cause as that referred to above.

Combined Effects.

To summarise these facts we find that with a body (say of a bird shape), parts of which are horizontal or inclined at a small inclination, driven rapidly through the air, the faster it travels the slower is its rate of fall. The portions of the body at a small degree of inclination are pressed upward with a considerable force. That the upper curved surfaces tend to cause a partial vacuum above sucking the body upwards, that the concave parts beneath only tend to lessen the forward resistance. All these favour the action of a flying body.

Here I have a little model of the general shape of a bird with wings half closed. It is propelled by two little screws rotated by twisted rubber, and you will see that it flies along rapidly in a horizontal course. But like all aeroplanes it requires careful balancing, not, as may often be thought, transversely (for a weight towards one side makes but little difference), but in a longitudinal sense. If dropped from a state of rest it at once falls on its head. Yet, if weighted so that the centre of gravity is near the centre of the figure, it will not fly at all, but at once points its nose straight upwards and turns a somersault backwards.

Actual Machines.

There are many other inexplicable problems not yet worked out, and is it to be wondered at if, under these circumstances, some of the larger models and man-carrying machines have been found to behave erratically, and not progress along on an even keel? During the last year quite a number of machines have been built in France, comprising large aeroplane surfaces propelled by screws. But one and all of them, after getting up a good speed on the ground, and then rising into the air—and this alone is a great triumph—have very shortly after toppled over and have fallen heavily to the ground. The two machines of Santos Dumont, those of Vuia, of Bleriot, and Delagrange, have all followed the same course. That of Elletrahmur, a Dane, is also said to have risen a few feet off the ground. The Wright Brothers have managed to stay up for long periods, but as far as one can gather facts it seems that this feat is only to be accomplished by the expert steering and balancing by these experienced aeronants, who have for several years been practising and making thousands of glides through the air in their motorless aeroplanes. These machines have been fully described and illustrated in the papers during the last month or two so that a detailed account of them is hardly necessary, but here is a Table summarising recent trials, from which important facts may be gathered as to the power, speed, and surface necessary to raise a given weight off the ground.

Aeroplane Machines.

	Span.	Area.	Total weight with operator.	Engine.	Propeller.		Speed attained	
					Diam.	Revs. per min.	On ground	In air.
	ft.	sq. ft.	lbs	h.p.	ft.		Miles per hour.	
Wright	40	480	925	24	2	—	—	38-40
S. Dumont (1)	39	560	550	50	6	1,000	24½	22-26
,, (2)	36½	146	500	50	6½	—	25	—
Bleriot ...	25½	140	600(?)	24	5¼	—	—	—
Delagrange	32·0	645	638	50	6·9	1,500	—	15
Vuia	—	215	605	—	7¼	—	—	—

All the machines are of much the same general type. All consist of one or more aeroplane surfaces, driven by a single screw propeller, about 6 feet diameter, mounted on wheels to run along the ground. The area varies from 1 to 3 lbs. per square foot of sustaining surface. The speed is from twenty to thirty miles an hour. This speed is very low compared to what one would expect an efficient machine to have. At such a speed, the pressure on a vertical surface would be from 1 to 2 lbs. per square foot, whereas if the speed were increased to 60 miles an hour the pressure would be 10 lbs.

per square foot. Of course it is really remarkable, or would have been considered so a few years ago, to get a speed of even 20 miles an hour over a grass field. But it is palpable that if by any means we can get up such a speed as 60 miles, in which there ought to be no difficulty, the lift should be merely 10 times as great.

But these trials teach us but little of the stability of the apparatus when in mid-air. I do not myself believe that this problem offers any insurmountable obstacle. I am inclined to believe, as the result of observing the behaviour of perhaps hundreds of small models, that an apparatus can be contrived which will automatically balance itself in the air, and even in a puffy wind, and if we can only arrive at the exact shape required (and there are doubtless many different shapes equally efficient) then it seems as if there was little else required before we can practically navigate the air. An old song said "We've got the ships, we've got the men," and we might add "we've got the engines too," but we must make sure, that these ships are stable and capable of pursuing their course, else we shall find that we have a deficiency of men !

DISCUSSION.

Mr. E. F. T. BENNETT asked the author if he would further explain the action of the flight of a dart.

Mr. W. H. MASSEY said he would like to call attention to a point which, in these days of sensational journalism, had been often concealed by design, namely, the danger of coming down. He hoped the Society would do something towards calling the attention of the British public, and especially of inventors, who were sure to break their necks unless they were very cautious, to that very grave danger. Major Baden-Powell had alluded to the fact that there was some difficulty, but he thought he had treated the matter too lightly. There was no difficulty whatever in making a machine which would run along the ground and raise itself and fly—supposing the atmospheric conditions to be favourable—any distance. He did not think with petrol there ought to be any difficulty in making a machine which would carry a ton of dynamite at nearly one hundred miles an hour for perhaps thirty hours, which would take one to America. Therefore, as far as the lifting and flying of the machine went there was no difficulty; but he did want people to realise how extremely difficult it was to come down safely. He supposed an economical speed for an aeroplane would be about 80 or 90 miles an hour. When one suggested to an inventor of a flying machine that there was a difficulty in stopping or unloading passengers or coming down, the inventor replied "Oh, there is no difficulty; use a parachute." If, however, when travelling in a train going at 50 or 60 miles an hour, you put a toy parachute out of the window, it would be realised how exceedingly difficult the thing was; in fact, it was impracticable. He had been thinking over the matter long before Maxim had carried out his experiments, and he had looked through scores of proposals for flying machines, but as far as he could see it was absolutely impossible to come down safely. People did not want to be encouraged to break their necks, and he hoped the Society would assist in making it plain to the world at large that until something was devised to make it possible to come down safely, it was worse than madness to continue reckless experiments in flying.

Mr. REGINALD MYER thoroughly agreed with the last speaker that, as things were at present, flying machines were impossible. He thought the engines which were necessary for flying machines were not, under existing circumstances, sufficiently powerful for their bulk. In some experiments carried out quite recently, it was found that not a single machine was capable of lifting its own weight. When the last speaker mentioned dynamite, he thought he was touching upon an idea which would eventually solve the problem of flying machines, namely, the use of high explosives for propelling engines. If the force of the explosion of dynamite or nitro-glycerine could be bottled up so as to be a little more gradual in its effects, a cwt. or so being capable of being exploded in small quantities, he felt sure it would lighten the engines of a flying machine so considerably that the possibilities of working them successfully would be very much increased; and if it was possible to work engines with a high explosive, the future of the flying machine would be very much more satisfactory than it was under the existing conditions.

Mr. MASSEY explained that he mentioned dynamite because Maxim's experiments were directed entirely towards aeroplanes for military purposes as a means of carrying explosives a greater distance than a gun.

The CHAIRMAN said that it was a fallacy to suppose that dynamite could be used as an agency for motor power, and the fact was quite recognsied.

Mr. C. R. MARTIN asked the author to give further information with regard to the action of two superimposed planes, and the utility of an upper plane.

Mr. T. W. R. CLARKE thought previous speakers had exaggerated the dangers of flying machines,

because if the records were referred to, it would be found there had been only one fatal accident of late in landing from the machines. The lamented deaths of Lilienthal and Pilcher were caused not so much from the difficulty in making the landing, but owing to the machines being too weak. The machines were of the single plane type, which possessed the disadvantage that it is very hard to stiffen them, and it was owing to the collapse of the machines in the air that the deaths occurred.

Mr. WALTER REID, after expressing regret that the author had not shown the very interesting models which he possessed, in referring to the question of high explosives, said he thought it would be the utmost folly to attempt to use nitro-glycerine. A cheap safe explosive could be obtained of petrol, mixed with air, and it was not necessary to get a greater power than the author had shown aeronauts already possessed, motors having been constructed weighing less than 2 lbs. per horse-power. That was very far in advance of any power that the flying organisms in Nature possessed. If one imagined that a bird weighing 2½ lbs. had the power of a horse, they would come to the conclusion it had as much power as was required. The important point was to apply that power, and that was the difficulty to be solved. The question of wind pressure was the first subject to be considered, and in that connection Professor Nipher of Washington University had made experimental demonstrations. By means of an anemometer he proved that the wind pressure recorded on the wall of a building against which the wind blew directly was not the true wind pressure. It was also important to remember that the same result was not obtained if the wind pressure was taken by an apparatus which was standing still, and if it was passed through the air. The only true way in which to test wind pressure for aeronautical purposes was to have the object with which the wind pressure was being tested in motion, because it created currents of air as it passed through the air quite different from what were created if the wind was simply blowing against it. Professor Langley had what he called a whirling table, an instrument with a very long rotating arm, at the end of which he put his apparatus. He did not think experimenters ought to go into mathematical formulæ until they had worked the subject out further experimentally, because they were dangerous unless the data were correct to begin with, and they were not quite certain that at present the data were right. He would therefore rather see an inventor, even if he was insufficiently informed as to what others had done before him, work with his hands and make a thing that would not fly, rather than he would see a perfect formula put down on paper to deter those who wished to make machines. One point with regard to the width of planes which perhaps required working out more than any other was that narrow planes were very much more efficient than wide ones. Nearly the whole of the apparatus that had been constructed hitherto had rather wide planes; and if there was one thing more certain than another it was that the same bearing surface could not be obtained by putting one plane close to the other and piling them up in that way, the dead air from the one detracting from the buoyant action of the others. It was necessary to be very careful indeed, with a fluid like air, to have the planes at considerable distances from each other, whether before and behind, or below and above. As honorary expert to the Aero Club, he had lately had a good deal to do with aeroplanes, and he had found that was one fault which nearly all inventors made. They thought that a wide area had a very large sustaining power when it was going through the air rapidly, but that was not so. There was a very great loss in friction to begin with, and if the sustaining membrane were impervious it was worse still, because a membrane that allowed air to pass through it got rid of some of the dead air, exactly in the same way as a bird's wing did. He had also noticed that nearly every inventor used a fan of some kind, or helix. So far as his own experiments went and those of others, he thought a wing was far more efficient than a fan, the difficulty being the mechanical moving of the wing. The problem was a totally different one from the movement of ships in water, because water was a dense fluid, and the bulk of the vessel was propelled through the air by means of action on the water. In the air, however, the problem was totally different, and his experience went to show that the wing form was more efficient than the fan, though he would not say that a fan could not be used. If a fan was used, however, it should be remembered that the central part was useless. It was of very little use in water, a boss having to be put on to guide the currents away from it, and in the air it was worse than useless. The most efficient propellers were those which had a plate at the end of an arm, which allowed the air to circulate freely round the shaft. In moving through the air, suction was created, as was demonstrated by the author's experiment, but with a certain breadth of the plane moving through the air a suction in front was also obtained. It was a very well known fact that certain forms of valves were in existence in which if a stream were blown against them they went against the current going towards it, and that fact was of the very greatest importance in dealing with aeroplanes. The question of coming down was an extremely difficult subject, but it had been very efficiently solved with balloons. Earlier aeronauts were dragged over the ground, their limbs were injured, and great damage was done; but now by means of the rip valve they were able to come down pleasantly and easily. He thought in the same way, human ingenuity, once they were able to get up and go along safely, would devise a safe means of coming down; but in the meantime he advised

anyone who wished to try the experiment to do so over water, and to learn how to swim first.

Mr. James Roberts enquired whether any observations had been made with regard to the fact that birds, apparently without any exertion on their part, could keep up so well with the wind, and whether any discoveries had been made which would facilitate the construction of flying machines, because he thought the principle which underlay the question of the flight of birds would give the key to many of the problems under discussion, which were often undiscovered for want of the necessary facilities for observation.

Lieut.-Colonel Allan Cunningham stated that, having seen the machines exhibited at the Agricultural-hall, he noticed that the majority of them were woefully deficient in balance, some in lateral balance and others in longitudinal balance, but they were not deficient in power for the size of the machines and the distance they were intended to fly. A great number of the machines came to grief very soon after leaving the exhibitors' hands from that cause. One of the most successfully balanced machines had a string fastened to its tail, and the exhibitor by pulling the tail was able to guide the machine, which did not plunge forward as many of the others did. By that means the exhibitor was able to keep the nose of the machine up, and in that way it flew in quite a respectable manner. In another machine the power was applied to the wrong place. The source of power was derived entirely from a sort of rocket applied to the tail, which caused the nose to plunge down almost immediately. The power required to be applied in some way to be determined upon by experiment, and partly depended on the centre pressure when the machine was in motion and partly on the centre of gravity. As a flying machine was wholly immersed in the fluid in which it was moving, it was natural to suppose that the problem to be worked out was similar to that of the submarine boat, which was wholly immersed in the fluid in which it moved. Those two kinds of motion were quite different from that of a ship, which was floating in the water with the heavy part immersed, and a great deal of the hull above the water. The problem of balance had been solved with considerable success in submarine boats, and he thought that by studying the problem of the balance of aerial machines great progress ought to be made; but until that was done much success could not be expected.

Mr. C. R. Martin stated that if anyone desired to watch birds they could so so on the cliffs between Folkestone and Dover. If they hid themselves behind the bushes on the cliff side they would see many hawks and other birds at close quarters. As far as he had been able to see, a hawk never aeroplaned; he always balanced himself on his wings when he was moving along, and he therefore thought that a hawk as a sample to copy was a mistake. It appeared to him that most inventors of aeroplanes had taken the hawk as their example.

Mr. E. F. T. Bennett remarked that birds in a wind could remain quietly without moving at all, which carried out the author's arguments.

Mr. Walter Reid, in reply to Col. Cunningham's remark with regard to the Howard machine, which obtained the second prize at the Exhibition, stated that a piece of tape was tied to the rear of the machine, but it was slack all the time. Trials were without the tape, and the machine then went better even than with the tape, because it went for a distance of 108 ft. 6 in. as against 71 ft. 4 in. with the tape.

Mr. Percival Spencer remarked that, being an aeronaut, he naturally took an interest in anything connected with the mastery of the air, but the lines of progress which he had thought the best to go along were by means of propelled balloons. He thought in the present state of knowledge a propelled balloon was the most satisfactory means of aerial navigation, because with an elongated balloon, with the power underneath, it was possible to go in any direction. That had been demonstrated to be a practical success. The French Government seemed to be of that opinion, inasmuch as they had taken up the Lebaudy airship, "La Patrie," and were using it for military purposes with entire success, it being capable of going a journey of many miles and coming back again. The fact that the navigable balloon was, for all practical purposes, a success, pointed to the necessity of it being taken into consideration in connection with the subject under discussion. There was no doubt, however, that the development of a machine heavier than air in the form of the aeroplane required careful study, and that the theory had been largely advanced by the experiments the author had conducted. He could not help thinking nevertheless that practical results and tests were more to be relied upon than theories, which were so often based on wrong foundations. In the recent practical tests that had been made, the Howard machine seemed far and away better than any other, it actually flying, and being of the simplest possible construction; whereas the machines of the box-kite type seemed to owe what amount of progress they made not to the flight but to the amount of push the inventor gave them. He remained in hopeful expectation that the development of flying machines would progress on satisfactory lines, and that he might shortly be in a position of leaving his trusty balloon, and taking to a flying machine which would satisfactorily carry him through the air.

Dr. Scott Tebb thought that from a military point of view, the subject was of extreme importance, be-

cause once flying machines were practicable, war ould be altogether stopped. Being a medical man, he was interested in the fact that birds had air sacs in connection with the body, while their bones were quite hollow, so that when they breathed they could practically blow out the body. He desired to ask the author whether that had any effect on their flying capacity.

Mr. J. K. COLLETT expressed the opinion that the problem of aerial transit was capable of solution, and that it was about to be solved.

Major BADEN-POWELL, in reply to the discussion, stated that a paper dart was simply an aeroplane, the pointed front of the folded paper causing the weight to come in the front. If such a dart which went through the air well was tested, he thought it would be found that its centre of gravity was very nearly ·3 of the surface back. He did not agree with Mr. Massey's remarks with regard to the danger of landing. Several inventors had made numerous experiments with gliding machines, jumping off a hill side, or by other means gliding down through the air to practice the balancing of a machine in the air, and no serious accident had ever happened. It was true that both Lilienthal and Pilcher were killed in making experiments of that kind, but in both cases it was not due to the landing; the machines broke in mid-air, or were upset by a gust of wind when at a considerable height. It might be said that was not quite the same thing, because the machine was not heavy and was not travelling at a great speed, but if such machines were able to land in safety, he did not see any argument why a bigger one travelling faster should necessarily be more dangerous. Reference had also been made to a flying machine travelling at the rate of 90 miles an hour, but it did not necessarily mean that the machine would be going at that rate at the moment of landing; it could then be slowed down. There were means of stopping the way of the machine, by tilting up the tail or the bows, and he did not see why there should be any more difficulty in stopping a flying machine than a bird experienced in stopping its flight. Somehow a bird always landed all right on its feet. Another speaker had referred to machines not being able to lift their own weight, but he (the author) had mentioned four machines which, though they had not made very successful flights, had at all events risen off the ground by their own power. With regard to the question of engines worked with high explosives, it seemed to him that the whole object of an explosive was to burn it as rapidly as possible. If it was required to burn slowly, there was an excellent fuel in coal, which he imagined would be much more economical than using dynamite. As Mr. Reid had remarked, he did not think it was necessary to trouble about the question of power at all, because very powerful engines could now be obtained with small weights. A question had been asked with regard to the action of two superimposed planes and the utility of an upper plane. He believed the chief idea of designers who made machines with two planes was that so much more strength was obtained, and that it was structurally convenient to place one plane over another instead of side by side; but he did not know that anybody had proved there was any special object in having two planes, so far as the current of air between them was observed. The box-kite was a very efficient and stable machine, but although it had come into great use he had always doubted whether it possessed any advantage over a single plane surface. He had not brought his models with him, because it was very difficult to show them in a crowded room, and also because they were very apt to be erratic. He intended to construct more models on the principle of the one to which he had referred in the paper, which he hoped to show at the meeting of the Aeronautical Society in July. The suction action on the back of the plane was a very important point, and this had just recently been investigated by Dr. Stanton, and it would be interesting to know the results he had obtained. Professor Bryan, a professor of mathematics, had recently given some lectures at the Royal Institution on the subject of aeroplanes in flight, discussing the subject from a mathematical point of view, and stating that it was necessary to discover mathematically how a machine should be balanced and then build a machine and try it, and that he did not care about risking his neck until that had been determined. Personally, he was afraid it would be a very long time before a machine was built by means of mathematics without practical tests. Mr. Reid had referred to the wing action of a bird as probably being more efficient than a screw propeller. He (the author) was not very much inclined, like some people, to imitate Nature in a slavish way. Birds had certain complicated actions, and it had often been suggested by some people that the biggest birds were the largest creatures that could be made to fly, and therefore that human beings would never be able to fly. A small bird flapped his wings very rapidly, and was able to easily rise directly off the ground; on the other hand, a large bird in almost all cases had great difficulty in doing so, having to flap his wings violently and make a great effort. He was inclined to think it was not necessary to imitate the bird at all, because birds had not anything to learn from insects in the way of flight, and in the same way he did not think a man had much to learn from a bird. He was in thorough agreement with the suggestion that experiments should be made over water, the few experiments he had made with large machines being conducted in that way. He was, at the present moment, arranging to make several big experiments over water, having been offered the use of a private lake in the country, where he hoped to do a lot of work in the summer. With regard to the question of

soaring birds, Langley's book, "The Internal Work of the Wing," threw a great deal of light on the possible solution of that question. In reply to Col. Cunningham's remarks, the experiment which he (the author) showed in connection with the exact point of balance was very important, from which it would be found there was a great difference whether the centre of gravity was at a point ·3, or ·33 of the distance from front to rear of the aeroplane. He noticed the rocket arrangement tried at the Alexandra Palace particularly, and noticed that the rocket was pointing downwards, which must drive the back up and the front down. With regard to the question of sailing birds, in his opinion, the most interesting part of the Exhibition at the Palace was Mr. Weiss's models similar to birds which soared down and looked exactly like soaring birds, travelling long distances with great steadiness. He considered that balloons were very dependent on the weather, and were difficult to manage and house. It was quite a fallacy for Dr. Scott Tebb to think that birds had air vessels in them which assisted in their levitation, the amount of air which they could get into their bones in such a way being such a minute quantity that it would hardly make any difference in their lifting power.

The CHAIRMAN, in proposing a hearty vote of thanks to Major Baden-Powell for his intensely interesting paper, thought the audience would be unanimous in coming to the conclusion that the problem of aerial navigation was a purely practical and not a mathematical one, and that it had not yet been perfectly solved. It was possible to take a little aneroid round a garden, and make a few experiments for oneself, while he had personally obtained an immense amount of information in the same way as to the variation of pressure on big bridges. On the front of a wall the needle pointed to a certain points, while at the back of the wall it pointed to an entirely different one, so that information was at once obtained as to the negative pressure at the back. If it was taken first to the weather side of a tree and then to the lee side, it would be found that the negative pressure was much smaller when a cylinder was being dealt with than when a flat plate was used. If it was used with an inclined plane, it would be found that the positive pressure at the edge on the underside was very much less than the negative pressure. How in the world any mathematical expression, even if one devoted one's whole life to it, could give the distribution of negative pressure on an inclined aeroplane he did not know. Fifteen years ago Lord Rayleigh told him that he had worked for two years before he succeeded in getting the positive pressure of a given velocity of wind on the face square to the wind. If one attempted to approach the subject mathematically in a practical way, it was perfectly hopeless; experiments with little pieces of paper such as the author used would give more information than years spent at mathematics. An aeroplane was navigated in a uniform fluid, but the problem was entirely different from that connected with submarines. There were vertical streams in the air of great velocity, which rendered it difficult to ensure getting an exact balance, although that might be obtained in still air. He thought there would always be a liability for the balance to be upset; and a margin of stability would be required in the construction of the machine which would give human agency the power of meeting those unexpected eddies.

The resolution of thanks having been carried unanimously, the meeting terminated.

SMALL HOLDINGS IN GREAT BRITAIN.

Attention has been drawn by the Board of Agriculture and Fisheries to the report of the Departmental Committee of Small Holdings (Cd. 3277), and in particular to the observations contained therein with respect to the present administration of the Small Holdings Act, 1892. This Act has been largely a dead letter, owing to the failure of County Councils to put its provisions into force. It may be gathered from the report of the Committee that Section 5 of the Act has been read as provided that the Small Holdings Committee of a County Council are not required to take any action until they receive a petition alleging that there is a demand for small holdings in a particular division of the county, and that the petition must refer to specific lands. The Committee point out that it is the duty of every Small Holdings Committee of a County Council to consider whether the circumstances of the county justify the Council in putting into operation Part I of the Act, and they suggest that in order to satisfy the requirements of the law in this respect, the Committee should on their own initiative make such enquiries as may be necessary to enable them to report to the Council. Under Section 5, every County Council is obliged to appoint a committee to consider whether the circumstances of the county justify the Council putting into operation Part I of the Act, but most of the County Councils beyond appointing this committee have done nothing more. The Committee has waited to receive applications, and in many cases none have been received, so nothing has been done. The Departmental Committee point out that so far all the Act requires is that the County Council shall get information to enable it to decide whether the circumstances of the county justify or not putting the Act in force in the county. If the Council finds in the affirmative, the next step is a petition from a county elector or electors praying that the Act may be put in force in some particular electoral division or divisions. The Act, as the Committee point out, does not expressly state this. It speaks of a petition praying that the Act may be put into force, but the next subsection making the local councillor or alderman

residing in the electoral division in which it is alleged there is a demand for small holdings, a member of the committee for considering the application, implies it. The next step is a reference to the Committee of the petition, and on their being satisfied of its being presented in good faith, and on reasonable grounds, an inquiry into the circumstances of the petition by the Committee, and a report on the result of the inquiry to the County Council. All these four steps are a necessary preliminary to any steps being taken under the Act to put Part 1 into force.

Among the recommendations of the Committee on the Small Holdings Act are the following:—

(*a*) That the purchaser shall pay down one-eighth instead of one-fifth of the purchase money.

(*b*) That the County Council shall have power to defer the payment of the instalments from time to time in such cases as they deem advisable.

(*c*) That power shall be given to County Conncils to acquire for small holdings purposes grazing rights other than those attached to any land acquired by a Council for sub-division.

(*d*) That an annual enquiry be made by each County Council Small Holdings Committee from the minor authorities within the county as to what land is occupied by small holders, whether there is a demand for further land, and whether there is any land available.

(*e*) That the attention of all County Councils should be called to the duty of their Small Holdings Committee to report as to why or why not the circumstances of the county would justify the council putting into operation Part 1 of the Act—the provision of small holdings. That petitions be received under Section 5 may be general, and need not refer to specific lands, and that the enquiry ordered under the same section of the sub-section need not be a public or local one

OUTDOOR ADVERTISING IN GERMANY.

Outdoor advertising displays are closely restricted in Berlin. Bill-boards are absolutely prohibited, but in place of such unsightly objects, public advertising is confined to a system of neat pillars or columns on the edge of the pavement at the principal street corners. These round hollow columns, called "Litfass Säulen," after the originator, are built substantially of iron and wood, about twelve feet high and three feet in diameter, the exterior having an advertising surface of from eleven to twelve square yards. The pillars are used principally for the advertisements of theatres and other places of amusement, for the announcements of papers and periodicals, and official notices. They are a conspicuous feature of Berlin street life, and are consulted regularly by theatre goers, &c. Much artistic ability is displayed in the arrangement of the differently-coloured posters, which are mostly in the form of reading matter, and not pictures. According to the American Consul-General in Berlin, that city advertised in 1901 for bids for the privilege of erecting and using these advertising columns within the limits of the city for the term of ten years, and the successful tenderers are paying an annual rental of £20,000, payable quarterly. According to the terms of the contract, the city covenanted not to grant a similar licence to anyone else. Newspaper kiosks, however, are permitted to have advertisements on their walls, consisting of wood, tin, iron, glass, &c. At that time there were seven hundred columns already erected, and the number was to be materially increased. The contractors were to erect them at their own cost, but both as to design and location the approval of the police authorities was to obtained, and they at once became the property of the city, all repairs and proper maintenance being performed by the contractors. The city has the right to use the interior of the columns for various municipal purposes, such as storing utensils for street cleaning and sand for use in the streets, for switch apparatus for public electric lights, and meters for electric street railways, &c. These columns, therefore, are provided with doors and locks, and the contractors have to keep the interiors properly ventilated and free of moisture. Each column must also have distinctly marked on the upper portion the number of the city district, and of the police station, the nearest sanitary station, the nearest accident station, and the nearest station. Delay in any payment, or violation or neglect of any condition on the part of the contractors, renders them liable to a fine up to £50, and may even cancel the lease. A bond for £2,500 was given for the fulfilment of the terms of the contract. The contractors have the exclusive right to use these places for advertising purposes, subject however to certain conditions. The rates for advertising, which are regulated by the Berlin authorities, are according to space occupied, varying from about fourpence halfpenny to two shillings and sixpence per day, the latter being for a space of nineteen by twenty-nine inches. For placards larger than that, the charges are in proportion. All placards must be approved by the police authorities before being exhibited. The contractors must keep a record of applicants for advertising spaces, and unless in cases of great urgency the applicants receive attention in their order. The city authorities have the right to demand at any time the free posting of such official notices as may be necessary, and for this purpose a special shade of red paper is used, and no private advertisements may, therefore, use that particular colour. The posting of bills on the pillars must always be done at such time as to cause the least possible interference with the street traffic. and is, therefore, usually done at night. Besides these "Litfass Säulen," the city of Berlin has also leased thirty "Urania" columns for advertising purposes for the annual rent of £780. These columns are somewhat more elaborate than the others, being solidly constructed of iron; the height is the same, but the interior is not used by the city.

They generally contain a large clock, various local official notices, and the advertisements slowly revolve behind glass windows. No promiscuous filling up of scaffolding on new buildings with advertisements is permitted in Berlin. The owner of a building may paint any exposed part of it with signs, or hang out signs, but permission must first be obtained from the police. At the present time multi-coloured, changing, electrically illuminated signs on the tops, and on the fronts of buildings and stores are very much in vogue, so that the business part of the city at night time is, here and there, dazzlingly brilliant. "Sandwich men" are occasinally seen in the streets of Berlin carrying boards, but this is regarded in Germany as a degrading form of labour, and consequently this kind of advertising is not much practised.

THE COTTON GOODS TRADE IN JAPAN.

In spite of the efforts of the Japanese to restrict the imports of cotton goods, and of the Japanese mills to control the home market, there were more cottons imported into the country during the first six months of 1906 than in the corresponding period of 1905, when there was a boom in the demand, caused by the war. To meet the national debt rigid economy is necessary on the part of the Government and the people, but with the rapid progress being made, more, and finer, cloth will be worn by the middle classes, and here is the opportunity of the foreign mills. Japan is making great strides in the development of her cotton industries, but is not building mills fast enough to control the coarse goods market in Manchuria and Korea, and also the demand for finer goods at home. It is the opinion of experts in Japan that in time, and probably very shortly, the coarse and medium grades of cotton goods made by Japanese mills will drive out all competition. They will also manufacture the finer goods, and they are endeavouring to build up a working force of highly-trained foremen, who in time would convert a larger portion of the working force into skilled operatives. In the meantime, every new factory established in Japan means a larger market for foreign goods, for with the increase of wealth caused by manufactures the needs of the people will increase, especially for foreign luxuries, fine cloth, &c., that they cannot make themselves, and any reduction in the importation of foreign cloths will be only temporary. In the first half of 1906, of the principal cotton goods, gray shirtings were brought into the country to the value of £364,000; sateens and velvets, £115,000; prints, £81,000; white shirtings, £79,000; drills £8,000, and duck £8,000. The abnormal imports of duck during 1905 (£178,000), caused by the war demand, as sails, uniforms, tent cloth, &c., have dwindled to small proportions, and in fact during the month of July, 1906, there was not a yard of duck of any kind imported. The market for drills is also rapidly shrinking, and is now unimportant. In these two articles there appears to be no prospect of much revival of business, as they are being made in sufficient quantities by the native mills. In a recent report to the United States Department of Commerce, by the Special Agent of that Department, it is stated that the Fugi Cotton Spinning Company at Tokyo and others, are now making drills to be khaki-dyed, and the uniforms of both officers and men of the army are now practically all made in Japan. The largest item in the cotton imporrs has always been gray shirtings. The close of the war caused an increased demand for this class of goods, and this demand still continues. There was a record importation in 1905 (£651,000); but for the first six months of 1906, the imports reached a value of £364,000, and for the month of July, 1906, alone, £129,000. This cloth is always 36 inches wide, and 50 yards long. It was formerly 40 yards, but is now usually made 50 yards. At the present time, there is a large demand for print cloth of all kinds. The demand that arose from the war has increased, and it is expected that more of this article will be imported than formerly. Of cotton sateens and Italian cloth, the demand is very good. The greatest proportionate demand during the first half of 1906 was, for cotton umbrella cloth. In 1899 not a yard of this cloth was imported. Immense quantities of flannel are now being turned out by the Kyoto Flannel Company, the Miye Spinning Company, and other cotton mills, besides a very large number of small weaving establishments. At present, the cotton flannel business in Japan appears to be overdone, and the demand is so slack that some of the mills are expected to close. There is at present not much demand in Japan for fancy cottons, fine dress goods, &c., but there is some business done at a profit in these articles. There is not much demand for imported dyed goods, the prints being more used on account of their cheapness. Like all Oriental nations, the Japanese prefer loose, flowing clothing, but they do not, as a nation, incline to the contrast of colours usually considered typical of tropical climate peoples. The Japanese dress very quietly. The babies are decked out in very gay colours, contrasts of purple, red, yellow, &c. The children wear mostly big patterns of "kasuri." This is the name given the large patterns of squares, blocks, lines, &c., and are mostly white patterns on a blue ground. Blue is a favourite colour in Japan, probably more so than any other single colour. The older they get, the more soberly they dress, and the men wear no loud colours. Black may be said to be the national colour in cloth, and the clothing mostly used is very narrow striped gray and black. The younger girls affect gay colours, and on holidays this is true of a large number of the people, but ordinarily the "daimio-jima" is the national costume. The name "daimio-jima," which means "daimio stripes," is said to have been derived from the fact that in olden times it was the distinctive dress of the Daimios. Next to the stripes, small white dots on a

blue ground seem in most common use. The higher and more wealthy classes still use silk for clothing, in fact its use seems to be extending rather than decreasing, owing probably to the increase of wealth *per capita*. There is also a good deal of imitation silk, silk and cotton mixtures, used especially for kimonos in daimio-jima. Woollen goods are being used in increasing proportion for clothing, especially underclothing, and this is a promising field for manufacturers. The majority of the poople dress in kimonos made of print cloth, and use chiefly the narrow 13 to 15 inch widths of print cloth, made in the native mills. These print cloths are made up in neat packages, tacked twice at each end, with attractive labels, and with a bunch of silk floss to match pinned to the front. They are in pasteboard cases in most instances. Some are sold wound up in a roll. For the better grades, there is also used a large quantity of the 30-inch imported print cloth, most of which is printed in Japan. The average Japanese buyer, whether wholesale or retail, is not very far-sighted. He buys goods on their appearance and feel, and not for their durability or wearing qualities. He goes to importing houses at Yokohama, or Kobe, looks at samples, and then orders so many cases, to be the same in appearance, but to be cheaper. The latter condition can only be obtained by lowering the quality, and this process is going on all the time. This is where some firms have lost ground. They either introduce the very best qualities whose prices are too high to meet the competition of others, or noticing the general tendency of the Japanese to buy close, introduce low-class goods, whose appearance is such that they do not attract the Japanese buyer. The common saying in Japan is that the American fine qualities are too high in price, and the cheap goods too poor. The English and Germans have reduced the production of attractive cheap goods to a science. Running cheap goods through hot calendar rolls, removing all filling threads, and putting up in neat bolts tacked neatly, attaching attractive labels, and carefully putting up in bales, are items that do not cost anything like it does to throw the goods out of the factory as fast as made, without a thought for their attractiveness to the buyer. The rough-finished, crumpled-looking goods may be made from better cotton, and more durable and lasting, but as compared with a smooth-finished, attractive looking article of really poorer wearing quality, they do not appeal to the buyer. More attention should be paid to the finish and method of putting up goods if a larger market is desired in Japan. In regard to trademarks or designs, simple pictorial marks, such as a dragon, butterfly, lotus, or something of the kind, is better than simple lettering, especially long words. This is for the reason that it is often translated into Japanese and long words are apt to be abbreviated. Pictorial representation will also catch the eye and be easily remembered. There is no prejudice against religious emblems, but the Imperial Chrysanthemum must not be used.

HOME INDUSTRIES.

The Malting Trade.—If it would be too much to say that the once flourishing and wealthy malting trade will soon be a thing of the past there can be no question that its present position and outlook are discouraging, and that no trade, or hardly any, has to face so many difficulties. It may be said of the malting trade that it is essentially a rich man's trade. The raw material has to be bought in large quantities, the credit given being exceptionally long. And it remains a private trade, for the unavoidable inequality of profits makes the business unsuitable for joint stock purposes, the public disliking to invest in companies which can only show widely varying returns. In other days the profits of the maltster were large, nowadays he finds it difficult to make any profit at all. The Fates seem to be fighting against him. The arsenic scare of some years ago was a serious blow to him, and though it was evanescent its effect upon him has been permanent and serious. The public demanded the most searching analysis, and specialists would report that arsenic was traceable, although in insignificant and quite harmless quantities, say, one seven-hundredth part of a grain in a pound of malt. But harmless as such a quantity would be it was sufficient to condem large quantities of malt, and to warrant and, indeed, compel his customers to throw on the maltster's hand large quantities of malt that had been delivered. The maltster has done everything that science can suggest to him to eliminate even the seven hundredth part of a grain, and this has involved large expenditure. He no longer uses coke as a fuel, or moderately priced coal, but the best coal to be got. He uses malt polishers that the skin of the malt may be freer from dust, and he resorts to expensive devices for the purification of the heated air. All this means addition to working expenses at a time when the margin of profit is steadily decreasing from other causes. Then he has to reckon with the decrease in the consumption of beer. Whatever may be the cause—and opinions differ widely—the fact is indisputable that the consumption of beer, *per capita*, in this country is steadily diminishing. Although the brewing trade is the last to benefit from good trade, the present trade activity has been sufficiently prolonged to send up the sale of beer if, as some contend, the shrinkage of recent years was due to trade depression. But it has not done so to any extent, and there would seem to be ground for the conclusion that the working classes, who consume most of the beer, are spending their money in other ways than drinking beer. This hits the maltster much harder than the brewer, for when the brewer's sales diminish he naturally ceases to purchase from the malster. He has his own production of malt to draw upon in the first instance, and he only goes to the maltster when that is exhausted. There are large brewers who during recent years, when sales have been falling, have not made a bushel

less of malt for their own use, but the decrease in their purchases from the maltster have been very large, so that he has to bear the heavier part of the loss consequent upon decreased demand. Then again, some of the large brewery companies have erected extensive maltings, and wherever this is the case the maltsters necessarily lose a big customer. Nor must it be forgotten that the use of substitutes, raw grain and other things instead of malt, is rapidly spreading among all but the highest class of brewers. Some of the maltsters have sought compensation for loss in the home market by paying more attention to the export trade, and a good deal of malt has been forwarded to Australia. But transit presents great difficulties, and it may be doubted whether much will come of this trade. Altogether the outlook for the maltster is not hopeful.

The Rating of Machinery.—Mention was made in these notes (in the *Journal* of August 25th, 1905) of the unsatisfactory state of the law as it relates to the rating of machinery, and it was said (September 8th, 1905) that the London Machinery League had been formed to bring pressure upon Parliament to amend the Act of 1840, or rather to enforce the intentions of Parliament when framing it, intentions baulked by the contradictory decisions of judges, and the varying readings of municipal authorities. Since the passing of the Act, machinery has not been rateable *per se*' but it has been decided that in valuing buildings (such as factories) certain kinds of machinery are to be taken into account in ascertaining the rateable value of the premises. Under the existing law the line between the kinds of machinery which are, and those which are not, to be taken into account in ascertaining the rateable value of a factory is one that it is practically impossible to draw with any approach to distinctness. The consequence of a lack of uniformity in the methods adopted by different rating authorities in valuing premises containing machinery which is not so fixed as to mean a part of the freehold works considerablein justice, and seriously handicaps manufacturers in districts where the rating authorities think only of how much they can plausibly exact. The Government have promised to deal with the matter, but prefer to wait until they take up the whole question of local taxation. To meet this difficulty the London and Provincial Machinery League, of which the Lord Mayor is president, have proposed a Suspensory Bill, which provides that in the valuation of premises containing machinery not fixed, or only so fixed that it can be removed from its place without necessitating the removal of any part of the premises, the value of such machinery is not to be taken into account, but this provision is not to be applied to any machinery or plant used for producing or transmitting a first motive power, or for heating and lighting the premises. The Bill is of a temporary character, intended to bridge over the period until the Government is able to deal with the matter. Its terms would only be in force until December 31st, 1908, by which time it is hoped that a permanent settlement will have been reached. Nor is it retrospective. Indeed, it specially provides that assessments in force at the date of the commenceent of the Act shall not be reduced by reason of its provisions. The promoters of the Bill have a very strong case. They only seek to do at once what two Royal Commissions, sitting at wide intervals of years, have reported ought to be done, and it may be hoped that the Government will adopt it.

The World's Production of Gold.—The yield of gold mines may not, at first sight, seem to have much to do with Home Industries, but in fact it has a very important bearing upon them. The *Statist* (April 13th) has an interesting series of tables covering the gold production of the world during the last century, and illustrating the sensational growth of the last twenty years. Figures compiled by Professor Soetbeer show that in the first decade of last century the production of gold averaged £2,288,000 per annum, and by 1850 the average of the decade had risen to £7,044,000, the gold being valued at £4 per ounce, and the weights taken at 32⅛ oz. to the kilogramme. In the later forties and fifties came the great American and Australian discoveries. In 1850 the value of the world's production, according to the United States' mint estimates, was £11,600,000; in 1851, £17,200,000; in 1852, £36,550,000. Then there was a falling off. In the thirty years—1860-90—the annual production did not vary more than five millions as an extreme, say between £20,500,000 in 1882 as the lowest and £25,400,000 in 1871 as the highest. In the middle of the eighties gold was first exported from the Transvaal. In 1882 the production of gold from South Africa, Rhodesia, and the West Coast was practically nil; then came the Transvaal discoveries, and in the nineties those of Western Australia and the Yukon, Klondike. In 1893 production increased to £32,600,000; in 1898, the year before the outbreak of the war in South Africa, it had reached £57,486,000, last year it was roughly 81,000,000. In other parts of the world than those named there was also increase in production. The combined production of Mexico, Columbia, and Brazil in 1882 was estimated at only about £900,000. Last year Mexico alone yielded £3,260,000, while Brazil and Columbia together gave about £800,000. Guiana, Peru, and other South and Central American States, exclusive of Mexico, gave for 1905 approximately £1,500,000. India too, in recent years, has made steady growth. At the present time the Transvaal heads the list or producers, its yield for 1906 being roughly £23,600,000. The United States came next, with £17,636,000, Australia coming close with £17,191,000. Even the West Coast of Africa is moving upwards. In 1880-83 it only produced £48,000 worth of gold; in 1901 the production had fallen to £22,000, but since then it has

steadily improved until last year it reached the respectable figure of £878,000. It looks as if for some years to come the increased output of gold from the Transvaal will be larger than elsewhere, and that probably within the next five years the total production of gold will reach £100,000,000 per annum. During the last sixteen years the annual production of gold has increased from £24,260,000, in 1890, to roughly £81,000,000, in 1906. The effect upon trade is, and will be, very great.

Electrical Railways—Considerable progress was made during the past year with electrical railways in the metropolis. The Baker-street and Waterloo tube was opened for traffic in March; the second of the tubes constructed by the Underground Electric Railways Company of London was opened in December; the conversion from steam to electric working of the Hammersmith and City Railway was completed; the Metropolitan Company withdrew all steam trains from the tunnel sections of their line north of Baker-street, and the year saw the almost entire abolition of steam working on what is known as the "Inner Circle." Is the cost of working any less by electricity than steam? As yet the data is too imperfect to answer this question. A train mile basis would be misleading, since it would take no account of the element of time. With steam, the booked time for a train to perform the journey round the Circle, was 70 minutes. Under electric working, and with automatic signalling, the time is reduced to 50 minutes. The cost of the energy required per mile may be more in the case of electricity, but the earning power of the line is increased, because it is possible to pass over a greater number of trains. Then in the case of a company owning its own generating station, the more current that is used within the capacity of the station the lower the cost per unit will be, since the fixed charges remain the same whether much or little current is used, while in the case of train running all additional trains involve a proportionate increase in expense. With regard to matters of construction, the respective merits of the third-rail system as adopted on the underground lines and the tubes, and the overhead system, which is preferred on the continent, continues to be discussed. There are those who predict that in the course of a few years the third-rail system will be obsolete, and it is, perhaps, significant that the Brighton Company has decided to use the overhead method in the electrification of certain sections of their line. This decision will enable a better comparison to be made between the rival systems. As to fares, again, opinion varies a good deal. The Baker-street and Waterloo Company have adopted the differential system, and at the recent meeting Sir George Gibb said the change had worked well. There has been a very large increase in the 1d. and 1½d. fares, and the company are now carrying nearly 57 per cent. of their passengers at fares below 2d.

NOTES ON BOOKS.

"WHAT I SAW IN THE TROPICS." *

The writer of this book is an American, a well-known authority on rubber, and the editor of the *Indiarubber World*, of New York. Mr. Pearson has made many visits to the chief rubber-producing countries, and gives much useful and up-to-date information upon this rapidly growing industry. A perusal of the book leaves the reader impressed with the profitableness of rubber cultivation, and its rapid extension in recent years. Mr. Pearson begins with Ceylon, where he was much struck, as all must be who visit the island, with the excellent work done by the Royal Botanical Gardens, Peradeniya, under the supervision of Mr. Willis. The oldest planting of *Hevea* is at Heneratgoda Gardens, which is one of the Government gardens under the direct charge of Mr. Willis. It is here that the first successful planting of Para rubber occurred, and it is due to Mr. Willis and his assistants that we have any sort of knowledge of the growth and productiveness of the *Hevea* tree under cultivation. Their work dates back to 1876, under Mr. Thwaites, when 7,000 seeds sent from the Amazon to Kew Gardens, were set out, only 4 per cent. of them germinating. From Kew, about 2,000 plants were sent out in Wardian cases to Ceylon, and 90 per cent. reached the Gardens in excellent condition. These were set out in bamboo pots, and flourished almost from the beginning, but the planters had set their hearts on the *Ceara* tree, and paid little attention to the reports that the director of the Gardens made from time to time as to their growth. In 1897, forty-five trees that stand about 30 feet apart, and were then twenty-two years old, were messured at about 5½ ft. from the ground. The largest tree was 7 ft. 5 in., the smallest 2 ft. 1 in., the mean girth being 4¾ ft. From the Gardens in question, between three and four million Para seeds have been sent out to planters all over the Eastern tropical world, a wonderful practical piece of work, and one for which the tropical planter should be very thankful. Mr. Willis told Mr. Pearson that there were about 11,000 acres of *Hevea* plantings in the island, and as the annual production of seeds was about three millions, he thought the planting increase would be about 5,000 acres annually. The *Hevea* can be planted in sheltered valleys, up to 3,000 ft. altitude.

The rubber landed in Colombo costs 16 cents a pound, and Mr. Pearson gives estimates to show that fine Para rubber from Ceylon is very much more profitable to the grower than from the Amazon. In the one case he makes the planter's profit 1·03 dols., in the other only 0·56 dols. He admits, however, that the cost figures are very small, and that 20 cents a pound for cost in Ceylon would be nearer the mark,

* "What I Saw in the Tropics." Henry C. Pearson. The India Rubber Publishing Company, New York. London Agents, Arthur Wheeler and Co., Temple-chambers, E.C.

while Para rubber costs, landed in Para or Mandos, from 40 to 50 cents a pound. The care which the planters are expending upon the preparation of the rubber is the best sort of guarantee that the quality will be sustained. It may be interesting to describe the process carried out at a rubber-curing house of the best kind in Ceylon, where the milk is coagulated and the rubber prepared for market. This is a one-story brick building, 30 feet by 80 feet. At one end of the room is a long table upon which are hundreds of enamelled iron pans holding about one quart each. Into these pans the milk is poured through a cheese-cloth strainer after being previously strained in the field. To it is often added a very little acetic acid. This is allowed to stand over night, and in the morning there is to be found in each pan a pure white pancake of rubber, soft, spongy, and full of water. Each cake is rolled on a zinc-covered table with a hand-roller and much of the water thus expressed. The name of the estate is then stamped upon it with either a wooden or metal die, when it is ready for the heater room.

The heaters used are simply charcoal ovens, the ovens being spread on wire screens above the fire and left for three or four hours. By this time the pancakes have lost about 50 per cent. in weight, and are beginning to assume a darker hue. Cakes in this condition, if in South America, would be immediately marketed, but not in Ceylon. From the heaters they go to drying racks, where they are air-dried for a month or six weeks, the time depending somewhat upon the weather, and are shipped only after careful examination as to quality and dryness. The planter has to reckon with the risk of disease, and he is continually on the look-out for the appearance of it in the rubber, but intelligence and vigilance keep it under control.

The tapping of the trees begins just as soon as it is light in the morning, for through the middle of the day the *latex* does not flow freely, but starts up again about four o'clock in the afternoon, and is continued until dark. The trees are tapped when they show a girth of two feet, without regard to their age. No ladders or supports are used in tapping, as it is not found profitable to tap higher than a coolie can reach while standing on the ground. The tool is a very simple V-shaped knife with two cutting edges, and a single slanting cut about eight inches long has been found to be best, a tin cup being placed under the lower edge of the cut, and held in position by forcing its sharp edge under the bark. These cuts, by the way, are about a foot apart, sometimes closer, and all run in the same direction, the herring-bone and the V-shaped cuts being no more in evidence. The practise is also followed now of cutting a very thin shaving from one side of the cut every other day, eleven times; in other worde, re-opening instead of tapping. Before placing the tin cup under the cut, it is rinsed out in cold water to keep the *latex* from adhering to the tin, and also to keep it from too quick a coagulation. Experiments in scraping the dry bark from the trees have been very successful. Such stimulation to the lactiferous ducts stimulate the flow nearly 50 per cent. Some of the oldest trees, say 18 years, which gave an average of 3 lbs. a year, by scraping the dry bark doubled the output.

Mr. Pearson visited not only Ceylon and the Federated Malay States, but Mexico, Nicaragua, Costa Rica, Panama, Columbia, Jamaica, and Hawaii. He seems to be much impressed with the rubber-producing capacity of Mexico. Here the rubber tree is free from pests. In Mexico the *latex* flows apparently as freely at one time of the year as at another, but the dry season is the best for tapping as there is no rain to wash away the milk and the tree is resting then. Of the various means of coagulating that are devised by experts, the one that seems to appeal the most strongly to the Mexican planter is the use of juice of the "Amole" vine, the *Ipomoea Bona Nox*, which is abundant everywhere, and which apperently adds nothing to the rubber, and effects a quick and clean coagulation. The planter must be alert and careful in preparing his ground, and especially in getting his seed into the ground at the right time so that it shall have the proper start. Mr. Pearson seems to think that a considerable cultivation of rubber is possible in Jamaica. At the Hope Gardens, near Kingston, the *Hevea* and *Castilloa* are couspicuous. The former does not seem to be well at all, as it is spindling in its growth, and far from vigorous, but the *Castilloa* looked much more promising. It may not be generally known that Jamaica has its own rubber producer, a climbing shrub known as Milk Witte. Its botanical name is *Forsteronia floribunda*, and its stem yields a rubber which as long ago as 1891 was valued in England at over 3s. a pound. It is a good grade of rubber, and the *latex* is said to be very rich in caoutchouc. There can be little doubt that the profits now being got for the cultivation of rubber are encouraging planters all over the tropical world, wherever there is the conjunction of proper soil, climate, and cheap labour to engage in rubber cultivation. In Ceylon it is supplanting tea cultivation much as tea supplanted coffee. Even the Japanese are preparing to plant rubber in Formosa.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday Evenings, at 8 o'clock:—

APRIL 24.—"The Cultivation of India Rubber." By HERBERT WRIGHT, Controller of the Government Experimental Station, Ceylon. LIEUT.-COL. DAVID PRAIN, C.I.E., F.R.S., will preside.

MAY 1.—"The Defence of the Sea Coast from Erosion." By ALFRED EDWARD CAREY, M.Inst. C.E.

MAY 8. — "The Production of Coke and its Application in Domestic Fires," By PAUL SCHLICHT. CORBET WOODALL will preside.

MAY 15.—"Trypanosomiasis or Sleeping Sickness." By HERBERT W. G. MACLEOD, M.D., B.Sc.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

MAY 2.—"The Applicability to Indian Rivers of the Italian System of Dealing with Silt." By SIR EDWARD CHARLES BUCK, K.C.S.I., LL.D., late Secretary to the Government of India, Revenue and Agricultural Department.

MAY 30.—"Irrigation Colonies in India." By LAURENCE ROBERTSON, I.C.S., Under Secretary to the Government of India, Revenue Department.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

APRIL 23.—"Social and Economic Conditions in Australia." By the HON. JOHN WINTHROP HACKETT, LL.D.

APPLIED ART SECTION.

Tuesday evenings, at 8 o'clock:—

APRIL 30.—"Lustre Pottery." By WILLIAM BURTON. J. C. WEDGWOOD, M.P., will preside.

∴ A collection of examples of lustre pottery from the Victoria and Albert Museum, and from private owners, will be arranged to illustrate Mr. Burton's paper, and will be on view during the afternoon and evening of the day of the meeting.

MAY 28.—"Sheffield Plate and Electro-plate." By SHERARD COWPER-COLES.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

PROF. HERBERT JACKSON, F.I.C., F.C.S., "Detergents and Bleaching Agents used in Laundry Work." Three Lectures.

LECTURE II.—APRIL 22.—The alkalies used in laundry work—Their relative values and useful strengths—Bleaching agents—their composition and properties—Methods of applying bleaching agents—Their comparative value—Dangers in the use of bleaches—Methods of valuing bleaches.

LECTURE III.—APRIL 29.—The problem of washing—Textile fabrics: easy methods of distinguishing between them chemically and by the microscope—Shrinkage of woollen goods—Behaviour of various fabrics with detergents and bleaching agents—Influence of acids, alkalies, &c., on the individual fibres—Precautions to be observed.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, APRIL 22...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Prof. Herbert Jackson, "Detergents and Bleaching Agents used in Laundry Work." (Lecture II.)
Surveyors, 12, Great George-street, S.W., 4 p.m. Discussion on Mr. Leslie S. Wood's paper, "The Improvement of our Woodlands."
British Architects, 9, Conduit-street, W., 8 p.m.
Medical, 11, Chandos-street, W., 8½ p.m.
Victoria Institute, 8, Adelphi-terrace, W.C., 4½ p.m. Professor Sir William Ramsay, "Exploration in Asia Minor, as bearing on the Historical Trustworthiness of the New Testament."

TUESDAY, APRIL 23...SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Colonial Section.) The Hon. J. W. Hackett, "Social and Economic Conditions in Australia."
Royal Institution, Albemarle-street, 3 p.m. Professor W. Stirling, "Stimulation, Luminous and Chemical." (Lecture I.)
Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m.
Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. Discussion on Mr. P. Allan's paper, "The Pyrmont Bridge, Sydney, N.S.W." 2. Mr. W. H. B. Savile, "Swing Bridge over the River Avon, at Bristol."
Photographic, 66, Russell-square, W.C., 8 p.m. Messrs. E. J. Wall and C. P. Butler, "The Spectroscope." (Part II.)
Zoological, 3, Hanover-square, W., 8½ p.m.
Antiquaries, Burlington-house, W., 2 p.m. Annual Meeting.

WEDNESDAY, APRIL 24...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Herbert Wright, "Rubber Cultivation in the British Empire."
United Service Institution, Whitehall, S.W., 3 p.m. Captain G. A. Charrier, "Bonaparte's Campaigns in Italy—1796."
Royal Society of Literature, 20, Hanover-square, W., 4½ p.m.
British Astronomical, Sion College, Victoria-embankment, E.C., 5 p.m.

THURSDAY, APRIL 25...Royal, Burlington-house, W., 4½ p.m.
Royal Institution, Albemarle-street, W., 3 p.m. Dr. A. W. Verrall, "Euripides and his Age." (Lecture I.)

FRIDAY, APRIL 26...Royal Institution, Albemarle-street, W., 9 p.m. Mr. James Swinburne, "New Illuminants."
Art Workers' Guild, Clifford's-inn-hall, Fleet-street, E.C., 8 p.m. Paper on "Buttons and Clasps."
Botanic, Inner Circle, Regent's-park, N.W., 4 p.m.
Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. Address by the President.
Clinical, 20, Hanover-square, W., 8½ p.m.
Physical, Royal College of Science, Imperial Institute-road, S.W. 1. Mr A. E. Garrett, "Electrical Conduction Produced by Heating Salts." 2. Mr. W. S. Tucker, "The Influence of Pressure upon Convection Currents, and a Criticism of J. Stark's relation between Cathode fall of Potential and Temperature." 3. Mr. W. B. Croft, "Solenoids which are Turned by the Earth's Magnetic Field." 4. Mr. J. A. Tomkins, "Simple Apparatus for Mechanically Illustrating the Tangent and Sine Laws."

SATURDAY, APRIL 27...Royal Institution, Albemarle-street, 3 p.m. Prof. Sylvanus P. Thompson, "Studies in Magnetism." (Lecture III.)

Journal of the Society of Arts.

No. 2,840. VOL. LV.

FRIDAY, APRIL 26, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, APRIL 29, 8 p.m. (Cantor Lecture.) PROF. HERBERT JACKSON, "Detergents and Bleaching Agents used in Laundry Work." (Lecture III.)

TUESDAY, APRIL 30, 8 p.m. (Applied Art Section.) WILLIAM BURTON, F.C.S., "Lustre Pottery."

*** A Collection of examples of Lustre Pottery from the Victoria and Albert Mnseum and from private owners will be arranged to illustrate Mr. Burton's paper, and will be on view during the afternoon and evening of the day of meeting.

WEDNESDAY, MAY 1, 8 p.m. (Ordinary Meeting.) ALFRED EDWARD CAREY, M.Inst. C.E., "The Defence of the Sea Coast from Erosion."

THURSDAY, MAY 2, 4.30 p.m. (Indian Section.) SIR EDWARD CHARLES BUCK, K.C.S.I., LL.D., "The Applicability to India of the Italian Method of Utilizing Silt."

Further details of the Society's meetings will be found at the end of this number.

SAMPLES OF INDIA RUBBER.

A Collection of Samples of India Rubber, principally Colonial, arranged by Messrs. Edward Till and Co., was exhibited on Wednesday evening, 24th inst., in illustration of Mr. Herbert Wright's paper on the "Cultivation of India Rubber." The collection can be seen on Friday from 10 a.m. to 4 p.m., and on Saturday from 10 a.m. to 1 p.m. Admission by member's order, or on presentation of visiting card.

CANTOR LECTURES.

On Monday evening, 22nd inst., PROF. HERBERT JACKSON, F.I.C., F.C.S., delivered the second lecture of his course, on "Detergents and Bleaching Agents used in Laundry Work."

The lectures will be published in the *Journal* during the summer recess.

COLONIAL SECTION.

Tuesday afternoon, April 23; the HON. ALFRED DEAKIN, Prime Minister of the Commonwealth of Australia, in the chair. The paper read was "Social and Economic Conditions in Australia," by the HON. JOHN WINTHROP HACKETT, LL.D.

The paper and report of the discussion will be published in a future number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

EIGHTEENTH ORDINARY MEETING.

Wednesday, April 24, 1907; LIEUT.-COLONEL DAVID PRAIN, C.I.E., F.R.S., Director of the Royal Botanic Gardens, Kew, in the chair.

The following candidates were proposed for election as members of the Society:—

Evans, J. W., Cobalt, Ontario, Canada.
Lee, William Harold, Sudan Railways, Shendi, Egypt.
Madunji, Pandoorung, 925, Bhandarwada-road, Dadur, Bombay, India.
Muntri, Narayen Govindjee, 192, Worlee-road, Bombay, India.
Rule, Thomas, Oceana Consolidated Co., Ltd., Kaombi, Chiromo, British Central Africa.
St. Quentin, F. G. de, British Consulate, Prague, Bohemia.

The following candidates were balloted for and duly elected members of the Society:—

Broadbent, Denis Ripley, A.M I.E.E., A.M.I.M.E., Royal Societies Club, 63, St. James-street, S.W.

Davies, Henry A., The Hawthorns, Bradley, near Bilston, Staffordshire.

Edwards, Mrs. Helen Agnes, Flat C, Artillery-mansions, Victoria-street, S.W.

Fryer, Sir Frederic William Richards, K.C.S.I., 23, Elvaston-place, S.W.

Jayakar, Balaji Jagonnath, 41-43, New Wadi, Bombay, India.

Khaw Joo Tok, Penang, Straits Settlements.

Khoo Eu Yong, Penang, Straits Settlements.

Kirkham, Captain John Karkeek, Fontabello, Barbadoes, British West Indies.

Leckie-Ewing, William, Rupurara, Inyanga, Rhodesia, South Africa.

Lim Eu Toh, Penang, Straits Settlements.

Lim San Ho, Penang, Straits Settlements.

Lim Tek Suan, Penang, Straits Settlements.

Mackenzie, R. R., Belgaon Tea and Fibre Co., Ltd., Chittagong, India.

O'Conor, James Edward, C.I.E., Francesco, Church-road, Upper Norwood, S.E.

Ong Hun Chong, Penang, Straits Settlements.

Osborn, Lieut.-Colonel Philip Barlow, D.S.O., Zomba, British Central Africa.

Sarkar, Chandra Kumar, 31, Penang-street, Moulmein, Lower Burma.

Thio Siow Kong, Penang, Straits Settlements.

Thio Tiauw Siat, Penang, Straits Settlements.

Thomson, Sir James, K.C.S.I., M.A., Pea Hen Hotel, St. Albans, Herts.

Yeoh Ooi Gark, Penang, Straits Settlements.

The paper read was—

RUBBER CULTIVATION (WITH SPECIAL REFERENCE TO PARTS OF THE BRITISH EMPIRE).

By Herbert Wright.

The cultivation of rubber-yielding plants has been brought prominently before the public during the last few years, and has aroused considerable interest. At the present time almost every institution concerned with tropical products is directing its attention to rubber-yielding plants, and recent developments in Ceylon, Southern India, Malaya, and other parts of the world, appear to have presented an opportunity of an unparalleled type to the investing public. It is necessary to consider the potentialities of this tropical industry and to determine its present and future importance from the producer's standpoint, especially in British possessions.

Development of the Rubber Market.

The stimulus which has been given to the exploitation of wild rubber and the establishment of plantations is evident from a consideration of the figures showing the consumption and value of rubber during the last few years; the increase in value from about three to over five shillings per lb. has been encouraging to rubber planters, and the increase in consumption, as shown in the figures kindly furnished by Messrs. Hecht, Levis, and Kahn, has inspired confidence in all concerned. Furthermore, the developments in the past few years on Eastern plantations have shown that yields are obtainable which were once considered impossible, and the expenditure incurred in collecting and preparing the rubber is rapidly being brought near the minimum:—

Year.	World's consumption of rubber.	Range in value of fine Para, per lb.	Prices paid for some samples of plantation rubber.
	Tons.	s. d. s. d.	s. d.
July, 1899, to June, 1900..	48,352	3 8½ to 4 9½	4 0
July, 1900, to June, 1901..	51,136	3 6 to 4 4½	4 1½
July, 1901, to June, 1902..	51,170	2 11¼ to 3 11½	4 0
July, 1902, to June, 1903..	55,276	2 10¼ to 4 1½	5 0
July, 1903, to June, 1904..	59,666	3 9 to 4 11	6 0
July, 1904, to June, 1905..	65,083	4 5 to 5 9	6 8
July, 1905, to June, 1906..	62,574	5 0¾ to 5 8	6 3

Rubber, Gutta, and Balata.

The relative importance of the india-rubber, balata, and gutta percha industries is indicated in the following figures*:—

Annual Exports of India Rubber, Gutta Percha, and Balata. Average for Years 1901, 1902, 1903.

	Totals.	
Rubber	973,000 cwt. ..	£12,537,000
Balata	50,000 ,, ..	£387,000
Gutta	220,000 ,, ..	£2,014,000
	1,243,000	£14,938,000

The gradually increasing demand for raw rubber, the remunerative prices at present paid for it, and its relative importance among the products of the tropical world, are all that we can reasonably desire, and under

* Atlas of the World's Commerce, Part 7, 1906.

these circumstances we may naturally expect to see a fair amount of capital invested in many islands and territories in the tropical zone. It will be shown later how the "wild" rubber has been practically the only source in the past; the promising importance of plantation and semi-wild rubber has apparently, as far as many English capitalists are concerned, been more attractive, and a statement of the sums invested in notable properties will best serve our purpose.

PAID-UP CAPITAL OF RUBBER-PLANTING COMPANIES.

	£
Malay	2,048,281
Ceylon and India	415,213
Islands in Indo-Malayan region	651,123
America	765,000
Africa	430,000
Sterling equivalent of capital existing in Rupee and other local currency in:—	
Malay	532,748
Ceylon and India	370,566
Islands in Indo-Malayan region	28,333
Companies growing rubber in conjunction with tea, cacao, and other products	9,121,761
Grand total	£14,363,325

These figures, kindly furnished in March, 1907, at my request by Mr. Fritz Zorn, show about five-and-a-quarter million sterling, invested in rubber alone, an amount which is being daily increased, and one which, if viewed in the light of the premiums at present obtainable for many of the shares, is considerably higher than the sum quoted here. It should also be remembered that only the paid-up capital is here dealt with, and that since the figures were compiled, other companies have been successfully floated in England.

You will observe that, in the foregoing table, only those companies registered in Great Britain, Ceylon, India, and Malaya have been taken into account. English capital has also been invested in the cultivation and exploitation of rubber in numerous East and West Indian islands, in tropical America and Africa, and very large sums from Continental areas have been supplied for the same purpose. These have been entirely omitted in the figures given in this part of the paper.

As most of you are aware the shares of many concerns, now prominently before the public, are standing at very high premiums, representing, in many cases, from three to eight times the paid-up capital; there are numerous semi-public and private properties in the Indo-Malayan region, about which little can be at present divulged; numerous cacao, tea, and coffee estates are gradually but surely being supplanted by rubber-producing species; large areas are being daily alienated for rubber; forests, with indigenous rubber plants, are being exploited under scientific guidance; and almost every tropical institution has turned its attention to this seemingly profitable cultivation. But neglecting all these side developments, it may be safely stated that to-day there are no less than fourteen million pounds of English money represented as paid-up capital, in companies directly or indirectly concerned with rubber-growing, and registered in England and our East Indian possessions. Furthermore, it may be estimated that approximately £30,000,000 worth of rubber may be consumed during the present year. These facts, though indicating that large sums of money have been vested in the production and utilisation of rubber, are insignificant compared with developments which are at the present time in an embryonic stage. Nevertheless, they show that the cultivation and exploitation of rubber plants have to be taken seriously, and, barring unforeseen developments, we may expect the final result to be such that British possessions in the tropics will be placed in the front rank as producers of plantation rubber.

SOURCES OF RUBBER.

Having seen that the consumption of rubber is on a sufficiently large scale to lead to the investment of several million sterling in its exploitation, it now becomes necessary to deal briefly with the sources of production. The most striking feature is the almost absolute dependence, to-day, of the manufacturers on the rubber obtained from trees indigenous to certain tropical forests and their independence of the plantation product. It is necessary to point out that tropical America is the most important centre for rubber collection (about 60 per cent.), tropical Africa the next (30 to 35 per cent.), and tropical Asia the least important, since it only contributed, last year, a very small proportion (about 3 per cent.), made up of wild and plantation material. It is of interest to recapitulate that the richest wild rubber areas in tropical America (Brazil, Venezuela, Bolivia, Peru, Central America, and Mexico), and in tropical Africa (Congo Free State) are not British, though capital

from this country has been recently diverted to parts of these two vast continents for the exploitation of rubber.

Tropical America.—In tropical America the only British possessions of much importance are British Honduras and British Guiana. British Honduras is a colony on the east coast of Central America, having 90 square miles out of a total of 7,562 square miles under cultivation. *Castilloa elastica* is described as occurring near the rivers Belize, Sibun, and Mullins. The colony produces very little rubber at the present time, and that only from wild trees near the coast; the available statistics* show a gradual decline in the export of this produce:—

EXPORT OF RUBBER.

Year.	Weight in lbs.	Value in dollars.
1901	40,044	23,237
1902	30,338	14,163
1903	22,176	13,002
1904	28,042	18,262
1905	22,926	15,921

The Statistical Abstract † shows only 20,111 lbs. exported, valued at £2,815, for British Honduras in 1905.

British Guiana, which is a portion of the South American Continent, though bounded on the east, south, and west by Dutch Guiana, Brazil, and Venezuela respectively, is not so much noted for its rubber export as for its "Balata," and under the heading of "Rubber Production" for that country, the Statistical Abstract for 1906 gives the following, without distinguishing the small quantity of rubber from the large quantity of balata:—

Year.	1895.	1900.	1905.
Quantity in lbs.	159,524	425,571	497,829
Value in Sterling	£8,923	£19,585	£41,487

* Colonial Report, No. 515, British Honduras, 1905.

† Statistical Abstract for the several British Colonies, Possessions, and Protectorates, 43rd No., 1906.

Tropical Africa. — In tropical Africa—though British possessions concerned in exporting or collecting rubber do not compare very favourably with the Congo Free State and other areas—there are indications of wide-spread activity from the most northerly districts of the West Coast to Natal in the south-east of that Continent. The following figures* show the changes during recent years in British rubber-producing areas in Africa:—

Country.	Quantity in lbs.			Value in Sterling.		
	1895.	1900.	1905.	1895.	1900.	1905.
British Central Africa Protectorate	563	86,404	17,280	28	9,332	2,160
Uganda Protectorate	—	—	101,164	—	—	13,305
British East Africa Protectorate	104,850	100,600	144,032	8,192	10,060	18,929
Protectorate of Southern Nigeria	308,309	2,251,315	2,842,831	11,787	137,289	226,387
Colony of Southern Nigeria (Lagos)	5,069,577	596,332	274,144	269,893	48,239	23,791
Gold Coast	4,022,385	3,452,440	3,687,778	322,070	328,156	323,774
Sierra Leone	1,429,680	274,624	426,610	86,940	25,741	49,132
Gambia	—	—	9,071	—	—	915

In British Central Africa the cultivators are encouraged to plant rubber vines and trees; there is no export duty on cultivated rubber,† but one of 4d. per lb. is levied on all rubber from wild plants. There are, at present, about 850 acres cultivated with *Ceara*, *Landolphia*, *Castilloa*, and other rubber-yielding species, the large cultivated properties being in the Blantyre and Zomba districts. It is stated‡ that very little rubber is now obtained from the Protectorate itself, and the following details are given in the Colonial Report for 1905-6:—

Year.	Crop exported to 31st March of each year. (lbs.)	Valued at £
1898	21,416	1,059
1900	118,720	13,356
1902	14,393	1,619
1904	4,262	426
1906	17,283	2,160

In the Uganda Protectorate there has been a renewal of interest and activity in the collecting of rubber from wild trees owing to the discovery of large numbers of valuable trees and vines in local forests. In the Mabira Forest, Uganda, Dr. Cuthbert Christy esti-

* Statistical Abstract for the several British Colonies, Possessions, and Protectorates, 43rd. No., 1906.

† Colonial Report, No. 499, B.C.A. 1905-6.

‡ "Bull. Imp. Inst.," London, Vol. IV., No. 4, 1906.

mates that in an area of about 54 square miles there are approximately 1,760,000 rubber trees; the value of this and other important statements will be discussed shortly.

In British East Africa, under whose administration all the Uganda provinces east of Lake Victoria were placed in 1902, large areas of land have been leased to rubber collectors, chiefly Indian and Arabian, and numerous experiments are now being made with indigenous and introduced rubber-yielding species, near Mombasa. According to one authority, the chief rubber areas* are (1) Coast strip, running from 5 to 20 miles inland; (2) Kitui area; (3) Laitokitok; (4) Ravine; (5) Kamasia; (6) Nandi; and (7) Lumbwa. The same authority states that there is a 10 per cent. export duty on rubber, and that the amount exported during 1905 was valued at approximately £15,000.

In Northern Nigeria small areas are now being planted with rubber, and recommendations have been put forward advising that large plantations containing the best kinds of rubber plants should be established without delay. In the year 1905-06 rubber formed nearly three-fourths or 68 per cent. of the total value of the exports, but regret has been expressed at the destruction of rubber vines occasioned by the methods of collecting commonly practised. According to the latest report† "an Ordinance has been evolved, the principle of which is to hold the purchaser responsible that no *root* rubber is bought or exported. It, however, appears difficult to distinguish between rubber prepared from the root and that from the stem, and it is now under consideration whether the latter should not also be prohibited."

The large export from Lagos in 1895 has been attributed to the introduction of natives experienced in tapping, from the Gold Coast. There has, however, been a decline in the exports during recent years from the Gold Coast itself, and it is hoped that this will soon be remedied. The export of rubber from Sierra Leone in 1905 was equal to 11·27 per cent. of the total exports for that country, and was exceeded, in proportionate value, only by palm kernels and cola nuts. According to the Statistical Abstract, 1906, "in Sierra Leone an Ordinance has passed the Legislative Council which provides for the prohibition of the exportation of root rubber from January 1st, 1907." Gambia shows in its export for 1905 a considerable fall, the previous year being responsible for 30,934 lb. of rubber valued at £2,446.

* Leaflet No. 14, Nairobi, Dept. of Agr., B.E.A.

† Colonial Report, No. 516, Northern Nigeria, 1905-06.

In North-Eastern Rhodesia, in Natal, and in the Soudan, rubber is still of considerable interest. In Natal, probably the most southernly point for rubber production in Africa, the Government some time back offered to lease the rights of rubber-collecting over immense areas for a period of five years. The Soudan was once largely indebted to the rubber industry as a source of revenue, but bad methods of collecting have evidently been adopted with disastrous results; a concession for extracting rubber in Abyssinia has been granted by Emperor Menelik.

Sufficient has been said to show that rubber vines and trees are distributed throughout many parts of Africa and America. The relative insignificance of our exports from British possessions in the West Indies and the Indo-Malayan regions is obvious from the following:

West Indies.—In the West Indian islands the cultivation of rubber-producing plants is not in a very advanced state. There is only one indigenous climbing plant of note, and the main experiments appear to have been with trees of *Castilloa elastica* and rubber trees as shade in association with cacao trees. In 1902 Jamaica exported about 230 lbs. of rubber; in 1903 Bahamas exported 84 lb.; Trinidad and Tobago exported in 1905 9,394 lb., valued at over £1,200. At the present time many experiments are being made with tropical American and African species in Trinidad, Tobago, Dominica, Jamaica, and St. Lucia, and the results will be detailed elsewhere.

Eastern Countries. — The Indo-Malayan region, which includes Southern India, Ceylon, Burma, Malaya, New Guinea, Borneo, &c., is at the present time one of great activity, and, though the past exports have not been by any means very large, much is expected from this area in the near future. There are several indigenous species of known value, but the future developments probably lie mainly in the cultivation of species from tropical America. The figures of export given below indicate the present insignificant position of our Eastern possessions as producers of rubber.

India.—In the year 1905-06 the export showed a further advance on that for 1904-05

* India Office Records, London, 1906.

by 40·6 per cent., and attained a total value of Rs. 12·82 lakhs; this refers mainly to wild rubber.

	1900 01.	1901-02	1902-03.	1903-04.	1904-05.
	cwt	cwt.	cwt.	cwt.	cwt.
Bengal	3,280	2,223	700	1,226	2,349
Burma	4,409	1,913	335	566	1,871
Total Export	7,698	4,136	1,035	1,792	4,220
Value in Sterling	£103,180	£40,280	£9,410	£23,146	£60,784

Ceylon and Malay States.—The following are the exports of plantation india-rubber from Ceylon and the Malay States for the last two years:—

	Ceylon.	Malay States.	Total.
1905	70 tons	75 tons	145 tons
1906	160 ,,	350 ,,	510 ,,

The export from Ceylon during 1906 does not represent that island's present producing capacity; about 80,000 lb. were re-exported from the Straits, and about 9,500 lbs. from China.

Ceylon.—The following figures show the development in the exports of plantation rubber from Ceylon:—

Year.	Approximate Quantity Exported.
1900	73 cwt.
1901	66 ,,
1902	189 ,,
1903	389 ,,
1904	676 ,,
1905	1,401 ,,
1906	3,200 ,,

New Guinea, Borneo, &c.—British New Guinea, in 1902, exported 12,983 lbs. of rubber, valued at £1,435, but during 1905 the collection of rubber was prohibited for the greater part of the year, and the total export was only 590 lbs., valued at £67. The rubber is obtained from indigenous species, but in 1905 and 1906 Ceylon sent a large number of other species to the authorities in New Guinea.

Borneo has long been known for the export of rubber obtained from indigenous species, and numerous estates have already been taken in hand in consequence of results obtained with tropical American plants. The planted acreage is rather small, but mature trees of *Hevea brasiliensis* are already known in that island.

The Seychelles, Fiji, New Caledonia, and other islands in the East, are also developing a strong interest in rubber-producing plants; as countries of export they may be largely neglected in this paper.

BOTANICAL SOURCES OF CAOUTCHOUC.

The fact that out of a total rubber export of about 65,000 tons for 1906, no less than about 38,000 tons came from tropical America, and about 17,500 from tropical Africa, compels us to look to these two great continents for the majority of the caoutchouc-yielding plants, and to place the whole Asiatic or Indo-Malayan region in a minor or third position of importance. Our first duty is to see which plants provide the caoutchouc in each area, and to trace the distribution of notable species from one country to another.

The natural order which has furnished, and which still supplies, the greater part of the world's rubber, is the *Euphorbiaceæ*; the valuable species of *Hevea*, *Manihot*, *Sapium*, *Micrandra*, and *Euphorbia*, which it comprises are indigenous mainly to the tropical American region, but have been distributed to all parts of the tropical world. Next in importance, perhaps, is the *Apocynaceæ*, remarkable in tropical Africa for the valuable rubber species of *Landolphia*, *Funtumia*, *Clitandra*, *Mascarenhasia*, *Carpodinus*, &c.; this order also comprises the genera *Chonemorpha*, *Xylinabaria*, *Tabernæmontana*, *Melodinus*, *Alstonia*, *Hancornia*, *Urceola*, *Willughbeia*, *Parameria*, *Diplorhynchus*, *Forsteronia*, *Leuconotis*, *Ecdysanthera*, *Micrechites*, known in many parts of the tropics for the quality of rubber they yield.

The *Urticaceæ* is also of importance in tropical America for the species of *Castilloa*, and for the genera *Ficus* and *Artocarpus* in parts of Africa and the Indo-Malayan region.

The *Asclepiadaceæ*, though it possesses such a large number of laticiferous species, abundantly distributed, especially in tropical Africa, is remarkable for the absence of good caoutchouc-yielding plants; true, the genus *Cryptostegia* in Madagascar and India furnishes us with a small quantity of caoutchouc, but the other important genera such as *Calotropis*, *Cryptolepsis*, *Marsdenia*, and *Cyanchum*, have not yet been found to yield latices of high commercial value.

Perhaps the most remarkable natural order in this respect is the *Compositæ*; though it is represented by such a large number of species and is to be observed in almost every part of the world, there are hardly any of value to the cultivator of caoutchouc plants; during the last few years, however, there is one member of this group—*Parthenium argentatum*, A. Gray—which has come to be regarded as the source of Guayule rubber

in Mexico, and another—a species of *Hymenoxys*—as the source of Colorado rubber. *Sonchus oleraceus, L.*, has also been mentioned by Jumelle as yielding caoutchouc of value.

Another natural order of note in this respect is the *Lobeliaceæ*, since the tropical American species of *Siphocampylus*, found in Columbia and Ecuador, have been said to yield caoutchouc of commercial value.

Distribution of important Caoutchouc Plants.

The geogrophical distribution of the more important caoutchouc-yielding plants is imperfectly known, but a general idea of the plant areas where certain species thrive can be given. Rubber-producing plants occur in both hemispheres, and are confined to approximately 25 degs. or 28 degs. north and south of the Equator. In this area the three most important regions are, following the floral regions of the world as divided by Drude: (1) the tropical American; (2) the tropical African, including Madagascar; and (3) the Indo-Malayan region. These three regions supply nearly the whole of the rubber of commerce.

Indigenous and Introduced Plants.—It may also be said that, of the three areas enumerated, the tropical American and African are, at present, only concerned with the extraction of latex from, and cultivation of, plants which are indigenous to those areas—*Hevea, Manihot, Funtumia, Landolphia*, &c.—whereas the Indo-Malayan region, though it possesses a few indigenous species of value, such as *Ficus elastica, Cryptostegia grandiflora* and others, is directing its attention, almost exclusively to-day, to the cultivation of species introduced from the tropical American region, and to a few from the African zone. The tropical American region has been the home of the plants which have led to the rubber industry in Ceylon, Straits Settlements, Federated Malay States, and Southern India, and has supplied even tropical Africa with species which rank as of first importance at the present time.

Trees, Shrubs, and Climbers.—Another interesting feature of the laticiferous flora of these three vast regions, is the nature of the plants predominating in each area. It may be said that the caoutchouc plants of the tropical American area, are mainly of an arborescent type, *e.g.*, *Hevea brasiliensis, Castilloa elastica, Manihot Glaziovii*, and *Sapium*; a few shrubby plants, such as *Parthenium argentatum*, and climbers such as *Forsteronia floribunda*, do of course exist there.

On the other hand, the rubber industry of the African region, especially if we include Madagascar, is principally concerned with climbers or lianes—*Landolphia, Clitandra, Carpodinus, Cryptostegia*, &c.; indigenous tree forms, such as *Funtumia elastica, Ficus Vogelii*, and introduced tree forms also abound in certain areas of Africa. In the Indo-Malayan region, on the other hand, there is a very mixed indigenous type, composed of huge tree forms such as *Ficus elastica* and *Sapium insigne*, and climbers, such as species of *Willughbeia, Cryptostegia, Urceola, Leuconotis, Parameria*, &c.

The introduced plants cultivated in the Indo-Malayan region are nearly all of the arborescent type—as *Hevea, Manihot, Castilloa, Sapium, Funtumia*, &c., with a few lianes, the most prominent of which is *Landolphia*. The Table given below will show the introduced and native plants now largely exploited for rubber in the three areas:—

Important Caoutchouc Plants.
(Generic Names.)

Tropical America (including the West Indies):—
- Native. — Hevea, Castilloa, Manihot, Sapium, Hancornia, Micrandra, Parthenium, Hymenoxys, Brosimum, Forsteronia.
- Introduced. — Funtumia, Landolphia, Castilloa, Hevea, Manihot.

Tropical Africa:—
- Native. — Landolphia, Funtumia, Ficus, Carpodinus, Clitandra, Cryptostegia.
- Introduced.—Hevea, Manihot, Castilloa, Cryptostegia, Ficus.

Indo-Malay:—
- Native.—Ficus, Willughbeia, Urceola, Parameria, Cryptostegia, Chonemorpha, Ecdysanthera, Leuconotis, Rhynchodia.
- Introduced. — Hevea, Manihot, Castilloa, Landolphia.

Rubber Species.

Most companies who have gone in largely for rubber cultivation have selected trees for planting purposes, which have become known in virtue of their caoutchouc-yielding capacities. There is, however, an extraordinary degree of laxity displayed by a few individuals who simply apply for, or say they have planted, *Hevea, Castilloa, Manihot, Ficus*, &c. It is as well to state that in each of these genera, as in many others, there are numerous species known to yield caoutchouc,

but in very variable quantities and of different qualities. Undoubtedly, in tropical America and Africa the latices of numerous species frequently contribute to the rubber exported in a form known under one name, and the real rubber values of many species of *Hevea*, *Sapium*, *Landolphia*, and *Manihot*, are but little known, except to the natives on the spot. There are some companies operating in tropical America who find it to their interest to cultivate a species of *Manihot*, other than *M. Glaziovii*, Muell. Arg., though the latter is the species which has been distributed to the East, and which everyone has hitherto associated with Ceara rubber for many years. During a very brief study at Kew, the importance of correctly identifying the caoutchouc species in wild areas for subsequent developments has strongly impressed me.

We will consider a few of the more important genera previously mentioned.

Hevea.—The genus *Hevea* furnishes the largest quantity, and perhaps the best quality, of rubber in the world. It is represented by *Hevea brasiliensis*, Muell. Arg., and *H. similis*, Hemsl., in Brazil, Eastern Peru, and Bolivia; by *H. spruceana*, Muell. Arg., *H. minor*, Hemsl., *H. benthamiana*, Muell. Arg., *H. rigidifolia*, Muell. Arg., and *H. discolor* in North Brazil; by *H. pauciflora*, Muell. Arg., in North Brazil and British Guiana; by *H. lutea*, Muell. Arg., in North Brazil and East Peru; by *H. confusa* in British Guiana, and by *H. guianensis*, Aub.* In the basin of the Amazon and in the south of Venezuela and the Guianas, species of *Hevea* are abundant and scattered among other forest types; further north they are replaced by *Castilloa* and *Parthenium*, and on the Atlantic side by *Manihot* and *Hancornia*. The map which I am able to show to-night by favour of John Bartholomew and Co., will indicate the distribution of the rubber-producing areas in the basin of the Amazon.

Among the species of *Hevea* enumerated above there are several which yield large quantities of latex, but *Hevea brasiliensis* is probably responsible for the greater part of the Para rubber of commerce. *H. benthiamiana*† has been confused with *H. brasiliensis*, and is said to be cultivated, at the present time, in some parts of Venezuela.

Sapium.—The genus *Sapium*‡ has been variously dealt with, and much confusion exists to-day regarding the botanical identity of the species which are of value as sources of caoutchouc. *Sapium mexicanum*, Hemsl., and *S. laterifolium*, Hemsl., native to Mexico, may be classed as doubtful sources of caoutchouc, though the juice of the latter hardens into a kind of india-rubber. In British Guiana, *S. Jenmani*, Hemsl., is known locally as Toukpong; *S. paucinervium*, Hemsl., is said to yield abundance of latex of a kind; and *S. aucuparium*, Jacq., is considered to be of doubtful value. In South America many other species occur, but do not appear to be of much commercial value. The species known as *S. verum*, Hemsl., which occurs in Columbia and Western Ecuador has, according to Hemsley, been confused with *S. biglandulosum*, once regarded as a polymorphic form, and the so-called source of "Columbia Virgen"; that occurring in Western Ecuador has been described by Dr. Preuss as being a good rubber tree. In North Brazil, *S. ciliatum*, Hemsl., is said to form a small tree from 12 to 15 feet high and to yield india-rubber. Another species † occurring in Venezuela, Columbia, and Ecuador and known as *S. stylare*, Muell. Arg., is said to yield its greatest quantities of rubber at an elevation of 5,000 feet, where the mean temperature is between 57 and 61° F. In Columbia and Ecuador the *Sapium* species are intermingled with those of *Castilloa*, and are considered to be the source of the white rubber "Caucho blanco;" in other parts of South America the trees are intermingled with *Hevea* species, the latex of both being mixed together in the preparation of certain grades of rubber.

Castilloa.—*Castilloa* is a genus represented by certain valuable species in tropical America. As in the case of *Sapium* the synonymy is a trifle confused, and will become more so if the representations of Cook and Seffer † are seriously considered. There are three species recognised at the present time, and other names have been given to forms which probably present certain minor differences when compared with the true *Castilloa elastica*, Cerv. *Castilloa elastica*, Cerv., *C. Tunu*, Hemsl., and *C. australis*, Hemsl., are the three recognised species in tropical America. *C. Tunu* was once confused, at Kew, with *C. elastica*; the name *C. markhamiana* has been applied to two plants, one of which (*C.*

* "Icon. Plantarum," Series 4, 8, 1905.

† Rubber planting in Mexico and Central America, Agr. Bull. of Straits and F.M.S., Jan., 1907.

markhamiana, Markham), turned out to be the ordinary *C. elastica*, Cerv., and the other (*C. markhamiana*, Col.) to be *Perebea markhamiana*, Hemsl. Cook and Seffer have suggested and used the name *C. lactiflua* for one form; others speak of varieties, rubra, alba, nigra, nicaraguensis, and so forth.

It should be clearly pointed out that *C. elastica*, Cerv., occurs in Mexico, Honduras, Guatemala, Salvador, Nicaragua, Costa Rica, Columbia, and Ecuador; in this range of latitude of about 37° it may be expected to show some variation according to habitat. *Castilloa elastica* is probably distributed over a wider range of latitude than any other rubber-producing plant, occurring, as it does, from Mexico to parts of Southern Brazil. It has been known to science longer than most other caoutchouc plants, having been first described by Cervantes* at a meeting of the Royal Botanic Garden of Mexico in July, 1794. In many parts of Mexico and Central America it is the only rubber plant exploited, but in other areas is the predominant type, and occurs mixed with species of *Sapium*. Its presence has not been confirmed in the Guianas and Venezuela.† It yields an excellent rubber. *Castilloa Tunu* occurs frequently in the forests of British Honduras and Costa Rica. It has been described as yielding rubber in abundance and of good quality. *Castilloa australis* has a limited distribution, and, though it often occurs in the Peruvian forests, has not been described as a good species for caoutchouc. Hemsley states‡ that it possesses a clammy, milky juice.

Manihot.—The genus *Manihot* contains one species—*Manihot Glaziovii*, Muell. Arg.—which yields Ceara or Maniçoba rubber. It occurs wild in the forests of Brazil,|| and its produce is shipped from the ports of Ceara, Bahia, and Pernambuco. It has been distributed to Africa, Mauritius, Madras, Burma, Ceylon, Straits Settlements, Seychelles, Zanzibar, Jamaica, Dominica, &c.

The wild trees of this species are not distributed over as large an area as are those of *Hevea*. The Brazilian forests containing large numbers of *Manihot* trees are mainly between 3 to 10 degrees from the equator, the eastern corner of Brazil, including the States of Ceara, Pernambuco, Piauhy, Maranhao, and Rio Grande do Norte, being of especial interest. Trees of *Manihot Glaziovii* occur at Para, and to the north-west this species is replaced by those of *Hevea*. In some parts of Brazil two plants are confused with this species; one is known as "Maniçoba"—the true form—and another, "La fraca," which is probably a variety of the same species, is described as being capable of yielding good caoutchouc.

There appears to be a species of *Manihot* differing widely from *M. Glaziovii*, which is now being cultivated in parts of tropical America; perhaps our Chairman can give us some information regarding an interesting species of *Manihot*, seedlings of which, I understand, are being reared at Kew.

Parthenium, or Guayule Rubber.—The name "Guayule" is given to the rubber obtained from *Parthenium argentatum*, A. Gray. This plant is a *Compositæ*; it is small varying from 8 to 40 inches in height, and has a much branched stem. According to Endlich, it occurs over a large portion of the bush prairies in Northern Mexico, and also extends into the United States; it is met with in Texas, New Mexico, and Arizona. Its occurrence has been reported but not confirmed in Southern Mexico, Central America, and Venezuela. It has been stated that the area in Northern Mexico, over which this plant is distributed, is about 29,000 square miles; it occurs from 3,000 to 5,600 feet above sea-level as well as upon the plateaux.

Hancornia.—*Hancornia speciosa*, Muell. Arg., is the name of the tree which yields the Mangabeira or Mangaba rubber of Brazil. It is widely distributed throughout Brazil, but is not regarded as being of exceptional value in Pernambuco, Bahia, Matto Grosso, or Sao Paulo. It has been reported in Bolivia and Eastern Peru. The tree attains a height of 13, 16, and 23 feet, is well supplied with branches, and grows well in dry districts at an elevation of 500 to 600 feet above sea-level.

Forsteronia.—This genus possesses two species, both lianes and natives of tropical America, which furnish useful rubber; they are found in Jamaica, and between Mexico and the South of Brazil. *Forsteronia gracilis*, Muell. Arg., occurs abundantly in British Guiana, where it is known, according to Jenman, by the name of "Macwarrieballi," and is said to yield rubber of good quality. *Forsteronia floribunda*, DC., appears to be found only in Jamaica, where it is known locally as

* "The World's Commercial Products," Parts 9 and 10, 1906.

|| Martius' Flora Brasiliensis, XI., Part II., p. 443.

the milk-wythe or milk-vine. It occurs as a climbing shrub in the forests in the interior of Jamaica, and yields a caoutchouc of value.

Hymenoxys or Colorado Rubber.—A species of *Hymenoxys** Cass., has been reported to occur "abundantly in the hills and mesas in the vicinity of Salida, the belt extending into the San Luis Valley, Gunniston County, and as far south as New Mexico." This plant is the source of what has been termed "Colorado" rubber, the roots often yielding as much as 10 per cent. of rubber of a somewhat inferior quality.

Micrandra, Brosimum, &c.—Before concluding the chief American rubber-yielding species, reference may be made to Micrandra, Brosimum, and Siphocampylus. The genus, Micrandra, is placed in the *Euphorbiaceæ*; two species are known which occur wild in Central Brazil, and are said to form part of the Amazon rubber. *Brosimum galachodendron*, the cow tree or "Palo de Vaca," is a large tree which occurs in South America and yields a resinous rubber. *Siphocampylus caoutchouc*, Don, occurs wild in Columbia, *S. Jameaonianus*, DC., in Ecuador, and *S. giganteus*, Don, in tropical America; all three are said to yield rubber of value.

African Rubber Plants.

Numerous plants are known in tropical Africa and Madagascar, but among the more notable genera we need only include, for our present purposes, *Landolphia*, *Clitandra*, *Carpodinus*, *Funtumia*, *Mascarenhasia*, *Pleiocarpa*, *Rauwolfia*, *Ficus*, and *Cryptostegia*.

Landolphia.—The genus *Landolphia* has supplied a great part of the rubber from Africa, and large numbers of these climbing plants have been destroyed by native collectors of rubber. There are about forty species known in this genus many of which supply large quantities of good caoutchouc; other species yield resinous latices and many yield abundance of rubber from their roots. Several species have been previously known under the genus *Clitandra*, and some confusion exists with regard to the nature of their latices as well as their botanical identity. Among the species said to yield good rubber are *L. Heudelottii*, A.DC., *L. Kirkii*, Dyer, *L. Dawei*, Stapf, *L. owariensis*, Beauv.; several species have been reported as yielding rubber of uncertain value or in doubtful quantities among which may be mentioned *L. kilimandjarica*, Stapf, *L. Buchananii*, Stapf, *L. Stolzii*, Busse, *L. droogmansiana*, De Wild., *L. Klainei*, Pierre, *L. reticulata*, Hallier, *L. petersiana*, Dyer, *L. Pierrei*, Hua, *L. lucida*, var. hispida, Hall. One of the most notable species said to yield root rubber is *L. Thollonii*, Demierve; it occurs abundantly in the French and Lower Congo and Angola. Much money and time have been wasted in connection with certain species; those which may be described as worthless for rubber purposes include *L. florida*, Benth., abundantly distributed in parts of Sierra Leone, Gold Coast, Lagos, British East Africa, &c., and also *L. ugandensis* Stapf, and *L. subturbinata*, Stapf. These plants, though they are not the most suitable for cultivation, are of much importance at the present time.

* Kew Bulletin, l.c.

Clitandra and Cryptostegia. — These genera furnish a small quantity of root and stem rubber. The important species of *Clitandra* appear to be abundant in the Congo, Liberia, Uganda, &c. *C. henriquesiana*, K. Schum., is an erect shrub said to yield root rubber; *C. orientalis*, K. Schum., which occurs frequently in the Congo Free State, and has recently been found by Dawe, at an elevation of 4,000 feet in Uganda, is a vine furnishing an excellent rubber; *C. Nzunde*, De Wild., *C. flavidiflora*, Hallier, *C. nitida*, Stapf, and *C. cirrhosa*, Radlk., are also described by some authorities as yielding rubber in Africa.

The genus *Cryptostegia*, to which we shall refer in another section, also furnishes species of value as rubber-yielding plants.

Carpodinus.—The value of most of the African species of this genus has often been discussed; many contradictory statements have been made regarding the value of the root-rubber from *C. lanceolatus*, K. Schum.; and *C. hirsuta*, Hua ex chev., *C. uniflora*, Stapf, *C. dulcis*, Sab., *Barteri*, Stapf, *C. acida*, Sabine, *C. oocarpa*, Stapf, *C. leucantha*, K. Schum., have been variously described as yielding rubber of good, variable, and questionable value.

African Rubber Trees.

Among the indigenous tree forms which are of value to rubber collectors those belonging to the genera *Mascarenhasia*, *Funtumia*, and *Ficus* are of the most importance.

The genus *Mascarenhasia* is said to possess several species of value, but it is doubtful whether their produce is of much importance

in the rubber export from Africa. *M. lisianthiflora*, DC., yields latex from which rubber possessing 88 to 91 per cent. of caoutchouc has been obtained; *M. anceps*, Boiv., and *M. longifolia*, Jum., are also said to yield good caoutchouc, whereas the products from *F. elastica*, Schum., and *M. utilis*, Bak., are described as being of doubtful value.

The genus *Ficus* possesses several species which are exploited by African rubber collectors: among those of note, may be mentioned, *F. Vogelii*, Miq., *F. whytei*, Stapf, *F. guineensis*, Stapf, and *F. johnstonii*, Stapf.

Funtumia.—This genus has lately become well known as a source of rubber in Africa. It is still much confused with the genus *Kicksia*, and it is as well to again point out that Africa does not possess a single species of *Kicksia* of value as a rubber-producing plant. The four species of *Kicksia* acknowledged by Stapf, are found only in Java, Celebes, Philippine Islands, and Borneo The genus, *Funtumia*, is partly African, and is represented by three species—*F. elastica*, Stapf, *F. africana*, Stapf, and *F. latifolia*, Stapf.

The species of importance as a source of rubber in Africa is *F. elastica*, Stapf; its occurrence has been recorded in Liberia, Gold Coast, Ashanti, Lower Nigeria, Cameroons, Mundame, French Congo, Congo Free State, Uganda, &c. The rubber from this species is very valuable, possessing, when properly prepared, from 80 to 90 per cent. of caoutchouc. *F. elastica* has been described as a tree with a cylindrical trunk which attains a height of 100 feet; sometimes the trees are very abundant in local areas; and out of an area of about 54 square miles as many as 1,760,000 trees have been estimated to occur.

EASTERN RUBBER PLANTS.

A few remarks can now be made regarding some indigenous species in the Indo-Malayan region. The most noteworthy genera are *Ficus*, *Cryptostegia*, *Leuconotis*, *Parameria*, *Urceola*, *Willughbeia*, *Chonemorpha*, *Ecdysanthera*, and *Rhynchodia*.

Ficus.—The tree known as *Ficus elastica* (L.) indigenous in Assam, Burma, and Malaya, furnishes a large proportion of the wild rubber exported from India. It grows to an enormous size, but cannot be tapped until it is many years old. It does not appear to have given as good yields either in the Indo-Malayan region, where it is indigenous, or in parts of West Africa, Egypt, and Ceylon, where it has been introduced. A species of *Ficus* has been exploited in British New Guinea, but as yet the reports regarding this are not very encouraging. The latices from *Ficus comosa* and *Ficus indica* sent from the Botanic Gardens, Calcutta, were examined by the Imperial Institute, London, but as they contained about 80 per cent. of resinous matter were reported upon as being almost worthless.

Cryptostegia.—The genus *Cryptostegia* furnishes two species of value as sources of rubber: *C. grandiflora*, Bra., and *C. madagascariensis*, Boj.; these are both lianes, and the former occurs in India. Many consider that *C. grandiflora*, is an Indian species naturalised in Madagascar, whilst others consider it to have been introduced into India from Madagascar. It is cultivated in a few gardens in India; the rubber is of fair quality, possessing about 80 per cent. of caoutchouc, though the harvesting, as at present carried out, is rather costly.

Leuconotis.—Plants of *Leuconotis eugenifolia*, DC., occurring in Penang, Sumatra, and Borneo, and *L. anceps*, Jack., of Borneo, yield very poor rubber; *L. elastica*, Becc., of Borneo, is, according to Beccari, a plant which yiel?s an excellent rubber, and the latex of *L. subavenis*, Boerl., also common in Borneo, is said to be used for adulterating purposes.

Parameria.—The liane, known as *Parameria glandulifera*, Benth., found more or less frequently in the Malay Peninsula, Burma, Andamans, Borneo, Philippines, &c., is said to yield a fair caoutchouc; the dry material may possess over 90 per cent. of caoutchouc. The latex of *Parameria pedunculosa*, Benth., has been reported upon by the Imperial Institute, but as the dry material possesses 88 per cent. of resin and only about 10 per cent. of caoutchouc, it cannot be said to be of much value.

Urceola.—Several species of this genus have been reported as yielding fair quantities of useful rubber. *Urceola esculenta*, Benth., common in British Burma and other parts of India, may yield dry rubber possessing 75 to 80 per cent. of caoutchouc. *M. elastica*, Roxb., found in Malaya; *U. acute-acuminata*, Boerl., occurring in Borneo; and *U. Maingayi*, Hook, f., found in Singapore and Borneo; these are described as yielding latices sometimes rich in caoutchouc. There is one species—*U. brachysepala*, Hook, f., which occurs in Malaya, Borneo, and Java, and is, according to Jumelle,

capable of being cultivated up to an altitude of 700 metres, and from which 25 grammes of caoutchouc have been obtained per plant.

Willughbeia, &c.—The plants of the genus *Willughbeia* grow into huge climbers analagous to the *Landolphias* of Africa; two species have been reported upon for their caoutchouc-yielding properties. *W. firma*, Blume, occurs, according to Stapf, in Sumatra and Borneo. It grows sometimes to a length of 40 metres, but the rubber from this species as it arrives in Europe loses sometimes as much as 4 per cent. in washing. The latex of *W. edulis*, Roxb., a species common in some parts of Assam and Malacca, yields a very resinous rubber possessing only about 10 per cent. of elastic caoutchouc-like substance.

The reports of the Director of the Imperial Institute on the rubber yielded by *Chonemorpha macrophylla*, and *Rhynchodia Wallichii* from Burma, and the latex of *Ecdysanthera micrantha* from Rangoon, show that in these plants there is much of interest to rubber cultivators.

It is obvious from the foregoing that there are very many species of rubber-yielding plants scattered throughout the tropical world. We may now proceed to study the wild and plantation species, and the nature of the channels in the tissue of these plants wherein rubber accumulates.

Wild Rubber.

Hitherto wild rubber has been obtained from forest trees or vines indigenous in local areas, and has been collected mainly by native labourers who have bargained their harvests for articles of food, &c., and who in their work have adopted methods requiring the minimum skill and involving the destruction of the plants. To-day the business of rubber exploiting in tropical America and Africa is being supervised by companies who are aiming at the preservation of the original wild plant, and in some cases the re-afforestation of areas poorly represented in wild rubber species, by indigenous or introduced rubber-yielding trees of known value. The terms under which much land has been leased provide that a definite acreage shall be planted each year, thus ensuring that the sources of supply shall be maintained.

Importance of Wild Rubber Supplies.—The sources of wild rubber are receiving much more consideration and care than was the case a few years ago, and may for many years to come be expected to supply annually the equivalent of approximately 1,000,000 acres of plantation rubber; should the supply from wild sources become scarce—an improbable occurrence—it would be impossible for the plantations to supply the balance for many years to come, as the producing capacity of the land now alienated for rubber in the East will only be, in 1912 or 1913, some 12,500 to 25,000 tons per year. The rubber manufacturers have hitherto been dependent, almost entirely, on wild rubber; and it seems illogical to suggest that the rubber forests on which so much new capital and enterprise have been recently expended, and in which prominent scientific and business men are concerned, will be unable to satisfy the increased demand expected in the next few years; it may confidently be regarded as the principal source of rubber for the next half-score of years, for the simple reason that plantations in the proper sense do not exist to produce what will be required.

Developments in Wild Rubber Areas.—Though the extraction of rubber from indigenous trees, vines, and shrubs in African and American forests has been hitherto mainly carried out at the sacrifice of the plants yielding caoutchouc it must not be surmised that this policy is always continued. Most of the companies of recent birth, formed for the exploitation of rubber from wild sources, are paying attention to the planting of areas which possess a fair proportion of rubber trees.

Many English companies operating in America and Africa are developing their properties in this manner, but for present purposes I cannot do better than give you an idea of what is happening in the Congo State, according to information obtained authoritatively and placed at my disposal by Mr. Johnston, of Little and Johnston, London. The information was obtained, I understand, from M. Arnold, Minister of Agriculture, Brussels, who has kindly sent numerous rubber samples, now submitted for your inspection. You will notice that rubber samples, labelled as follows, are included:—*Funtumia elastica*, *Landolphia klainei*, *L. Gentilii*, *L. owariensis*, *L. Thollonii*, *Clitandra Arnoldiana*, *Ficus elastica*, *F. negbudu*, *Manihot Glaziovii*, *Hevea brasiliensis*, as well as material from Lake Leopold II., Uelle, Aruwimi, Equator, Mongala, Lopori, and Kassai, in the Congo. Most of the material represents what can be obtained from plants indigenous to the Congo, but *Ficus elastica*

is native to India and Malaya, and *Hevea* and *Manihot* to tropical America. The following are some interesting extracts from the translation :—

"The State Laws, since the year 1899, have prescribed that there shall be planted annually a number of trees or creepers which shall not be less than 150 for every ton of rubber collected during the same period. In 1902, the number of rubber trees or creepers to be planted annually under the conditions fixed by law was increased from 150 to 500. In 1904 a new decree was made stipulating that whoever collected rubber in the forests or State lands, is bound to plant annually at least fifty young rubber trees or creepers, and fifteen root rubber plants per 100 kilograms or fraction of 100 kilograms of fresh rubber collected during the same period.

"On the 1st of January, 1906, the rubber plantations, established by the State, included nearly 9,500,000 plants, of which 8,575,000 creepers, 750,000 *Funtumia elastica* and 157,000 different trees, including *Hevea brasiliensis*, *Manihot Glaziovii*, *Ficus elastica*, *Castilloa elastica*, and *Castilloa Tunu*.

"To avoid losses resulting from the bad choice of land, the Government has authorised that supervision of the rubber plantations shall be made in each district, either in execution of the legal provisions or in conformity with Government instructions, at one or several places recognised as being favourable to rubber cultivation by the State agriculturists, the latter being charged with the supervision of plantation on behalf of the State.

"In 1906 the State sent more than 20,000 seeds of *Hevea brasiliensis* to the Congo . . . . orders for seeds for 1907 have already been given; at least 100,000 seeds will be sent.

"The State has decided to give extension to the cultivation of *Hevea brasiliensis* in the Congo.

"The State has procured 15 different instruments for tapping, reviving, and strengthening the rubber plants."

The same might be said of developments in almost every other part of tropical Africa and America, but the above will serve to show that there is likely to develop a pseudo-wild source of rubber in the future.

In some parts of Africa the trees of *Funtumia elastica* are said sometimes to occur in clusters and in such areas to be very abundant. In parts of Mexico and Brazil investigated by many botanists, *Castilloa*, *Hevea*, *Sapium*, and other species are said to occur frequently. But it must not be concluded that in such areas there are always large numbers of mature and tappable trees; in many parts of Mexico I have been assured, by a prominent resident there, that it is rare that one finds more than one or two trees of *Castilloa elastica* to an acre of land; what trees did exist in days gone by have been largely destroyed or rendered almost valueless by ruthless native tapping, and one can but conclude that in many instances the profits from the few wild scattered trees will be largely swallowed by the expenditure involved in the employment of skilled men in searching for them; of course, they are worth having, but their fewness makes one wonder whether the wholesale clearing of forest prior to planting as adopted in the East, where wild rubber trees do not exist, is after all a serious disadvantage.

Change in Wild Rubber Areas.—The material exported from the wild rubber areas in America will probably retain much of its present character, whereas that from tropical Africa may show considerable changes in the future and tend to become somewhat similar to that from America. This is suggested from a study of the developments which are now going on in both countries; in American areas attention is mainly directed to the cultivation and exploitation of species indigenous there, and though a few species of *Landolphia*, *Funtumia*, and *Ficus* from Africa and the Indo-Malayan region have been tried, they do not appear to give very satisfactory results. On the other hand, nearly every part of tropical Africa is carrying out extensive experiments with *Hevea*, *Manihot*, and *Castilloa* species from America, and in consequence of the success which has already been achieved one of the three American genera is likely to be largely adopted. The cultivation of climbing plants and of root rubbers is generally more difficult and expensive than that of arborescent forms, and it appears probable that the produce of the latter will largely increase and that of the former decrease in quantity. Judging from results obtained it appears to me, though I may be quite wrong, that the cultivation of species of *Hevea*, *Castilloa*, *Funtumia*, *Manihot*, *Sapium*, and arborescent forms similar to them, will predominate in the future, and that of species of *Landolphia*, *Cryptostegia*, *Clitandra*, *Carpodinus*, and *Willughbeia* gradually become relatively insignificant; plants of the former group require less supervision, they attain maturity at an earlier age, they allow of continuous tapping operations for years on the same tree, and under certain conditions yield rubber in larger quantity than do those of the latter class.

In the Indo-Malayan region, the indigenous species of *Cryptostegia*, *Leuconotis*, *Para-*

meria, *Rhynchodia*, &c., and even of *Ficus* and *Sapium*, are gradually being neglected in preference to those from tropical America. There the species of *Manihot*, *Ficus*, and *Castilloa* do not appear to give as favourable results as *Hevea brasiliensis*, and before very long that area will stand out remarkably for the uniformity of the greater part of its exported rubber. *Hevea brasiliensis* appears to have been taken up in the East, almost to the exclusion of all other rubber-yielding plants, and even the coconut palm has been felled in order to make room for this favourite species. It is very rare, in Ceylon, that one meets with plantations of *Castilloa*, such as are described to exist in Mexico, or of *Manihot* as in parts of Brazil.

Differences Between Wild and Plantation Areas.

Eastern rubber estates are nearly all planted; only a few possess indigenous trees or climbers, and the waiting period is consequently very long; properties in Malaya, possessing trees of the indigenous *Ficus elastica*, have usually all been regularly and systematically planted with seedlings reared in the nursery, and in this feature differ from the wild or pseudo-wild areas.

Again it may be stated, with some amount of accuracy, that the rubber output from most parts of tropical America and Africa is dependent upon native efforts; there the amount of skilled supervision is small compared with that on planted estates generally. I have been informed by residents in prominent wild-rubber areas that they have only a few practical men of repute. We know that in Ceylon, Southern India, Federated Malay States, Straits, &c., the estates are managed by Europeans of considerable tropical experience, and that their systems of keeping records and accounts, and their knowledge of engineering, languages, &c.—all of which play a very important part in the ultimate success of any rubber plantation—are such as to command complete confidence. The number of planters drawn from Ceylon to engage in the rubber industries of the Malay Archipelago is very large, and from a few years' experience in that island one can anticipate that good work will be done.

It is now generally admitted that *Hevea brasiliensis* has, on Eastern plantations, been proved to give excellent results, and to stand tapping operations even of a very drastic nature; this cannot yet be asserted for many *Castilloa* plantations in Mexico and Central America, or even for those of Ceara in Brazil, or *Landolphias* and *Funtumias* in Africa, though we naturally expect favourable results from many of these.

The plantations of rubber trees are, as most of you are aware, capable of being worked more economically than forests of mixed plants; the number of rubber trees is generally accurately recorded, they are capable of being minutely inspected daily, and there are often more rubber trees in one acre of an Eastern plantation than in several square miles of American or African forest. Of course, it is possible to plant up areas possessing indigenous rubber-yielding plants, but the abundance and cheapness of the Indian, Javanese, and Malay labour make it possible to do planting work cheaper in the East than in most parts of the tropics.

It is asserted by many that tropical plants will thrive best in their native habitats; this statement can be seriously contested, and is often contradicted by the results obtained from introduced plants in the tropics. True, the indigenous rubber-producing plants in the American and African forests represent types which, in their native countries, have survived in the struggle for existence, and have often successfully contested certain pests. But it is well known that a change of climate is often beneficial to the plants, and certainly the results obtained with introduced species in the East justify one in anticipating that the rubber plantation industry will give satisfaction to most persons interested in it.

Distribution of Rubber Plants and the Eastern Industry.

At the present time it may be stated that many trials of Brazilian species have been made in Africa, East and West Indies, India, Malaya, Borneo, Philippines, New Guinea, Fiji, &c., and of African species in parts of America and the East and West Indies. In the distribution of rubber-yielding plants to various parts of the British Empire Government have taken considerable interest.

The gradual development of the plantation rubber industry to the position it occupies today can be associated largely with the activity of the various Government Botanic Departments in different parts of the world. The Royal Gardens, Kew, naturally ranks of first importance in this respect, as a centre of distribution of species collected from all parts of the tropics. According to the Kew Bulletin

(No. 3, 1907), *Hevea brasiliensis* was first sent from Kew to India in 1873; in 1876 to Burma, Ceylon, Java, Singapore, West Indies; in 1877 to Mauritius and West Africa; and in 1878 to Fiji. Plants of *Hevea spruceana* were first despatched to Ceylon in 1883; to India, Java, Singapore, West Africa, and West Indies in 1887; and to Fiji in 1893. *Castilloa elastica* was first sent to India in 1875; to Ceylon, Java, and West Indies in 1876; to Singapore, Mauritius, and West Africa in 1877; and to Fiji in 1882. *Manihot Glaziovii* was first sent to India, Ceylon, Singapore, and West Africa in 1877; and to Java, Fiji and the West Indies in 1878. *Landolphia* plants were first despatched to Ceylon and the West Indies in 1880; to Singapore and Fiji in 1881; and to Mauritius in 1883; and to Java in 1888. *Funtumia elastica* was sent from Kew to India, Ceylon, Java, Singapore, and the West Indies in 1896, and a second consignment was forwarded to the same countries in 1897.

Ceylon.—The Ceylon Para rubber industry has been developed from the offspring of the plants originally obtained by, and for, the Indian Government in 1876 and 1877. These plants were sent to Ceylon, in whose Botanic Gardens they were carefully reared, and supplies distributed to many parts of the world.

As explained above, plants of *Castilloa elastica*, *Manihot Glaziovii*, and species of *Landolphia*, *Sapium*, *Palaquium*, &c., have also been received in Ceylon, from Kew and other Botanic Gardens direct. Rubber plants have been sent from Ceylon to the Straits, Borneo, Java, Philippines, Seychelles, Queensland, New Guinea, Africa, West Indies, and even Brazil.

Singapore.—The Botanic Gardens at Singapore have also received many rubber-yielding species from Ceylon, and other countries. Mr. H. N. Ridley has kindly supplied me with the following information:—Twenty-two plants of *Hevea brasiliensis* were received on June 11th, 1877, from Kew, and a further consignment was despatched from Kew in the following year; already very large and successful acreages have been planted from the offspring of these parents. In 1876, plants of *Castilloa elastica* and *Manihot Glaziovii* were received from Kew; the former were failures, and the latter are not looked upon with favour in the Straits. In 1898, plants of *Funtumia elastica* and *Mascarenhasia elastica* were received from Kew, but they appear to grow very slowly. Plants of the vines—*Landolphia Watsoniana*, *L. petersiana*, and *L. Kirkii* were received in 1881 from Kew, but none have been successful as cultivated plants, though nearly all grow well. In the same year a species of *Hancornia*, which subsequently failed, was also received from Kew. *Ficus elastica*, at present largely cultivated in the Straits and Federated Malay States, was received at Singapore before 1875. It is a native of Perak, and caoutchouc from the wild trees of this species was obtained before 1876.

India.—My information regarding the introduction of rubber-producing species to India has been obtained from Mr. I. H. Burkill, Officiating Reporter on Economic Products, Indian Museum, Calcutta. For many years thousands of seeds of *Hevea brasiliensis* have been annually sent from the Henaratgoda Botanic Garden, Ceylon, to the Government of India, and in addition to these, officials and planters have frequently secured seed supplies of other species from Ceylon and the Federated Malay States. I append a

INTRODUCTION OF RUBBER PLANTS TO INDIA.

Species.	When Received.	Whence.	No. of Plants.	Results Obtained.
Hevea brasiliensis	1873	Kew	6	Not favourable.
,, ,, ...	1876	,, ...	50	Reached in bad condition.

synoptical statement, showing the date of introduction of the more important foreign species, at present in India, supplied by Mr. Burkill.

Plantation Rubber.

These considerations bring us to the subject of the plantation rubber industry as at present developed in the three great rubber areas. Its exact importance in areas where indigenous species are exploited is difficult to ascertain, and the various compilations regarding this point show considerable differences in areas planted. Dr. Olsson-Seffer states that *Castilloa* is being planted over large acreages in Central America and Mexico, and according to him this work is proceeding in Guatemala, Nicaragua, Panama, Costa Rica, Honduras, and San Salvador; in the Central American Republics there are reported to be about 12,230 acres under rubber, mainly *Castilloa elastica*. In Mexico, according to Seffer, on December 1st, 1906, there were about 82,620 acres planted and a prospect of planting 10,000 acres more in 1907. Seffer states that "this area under cultivation represents at least £6,000,000 that are nominally invested in rubber plantations." In Ecuador, property owners have begun to plant trees of *Castilloa elastica*, and plantations now exist "especially round the Balzar and Fenguel districts and in some parts of the provinces of Manabi and Esmeraldas." The latest official report states that there are about one million trees now planted in Ecuador, and that over 95 per cent. of the present export is of wild rubber and only 5 per cent. of cultivated rubber. It is difficult to obtain any reliable information regarding the planted acreage in Brazil, the West Indies, and Africa, and beyond stating that the operations contemplated are on a very large scale, I do not propose, at present, to commit myself.

Indo-Malayan Plantation Rubber.

We do, however, possess some detailed knowledge regarding the plantation industry in the East; and as Ceylon, Straits Settlements, the Federated Malay States, Southern India, Borneo, &c., are now of considerable importance, in this respect, we may devote some attention to this area.

Southern India.—Mr. Windle, in his lecture at the Ceylon Rubber Exhibition in September, 1906, made the following statement:—

"In 1903 some good-sized areas were opened, and since then planting has been extending fast. I should put 1904 as the year in which, with the exceptions mentioned, Southern India really began its serious planting of rubber. As to areas open to the present time, I have done my best to collect some figures on the point, and am fairly certain that they are not under the mark:—

	Acres.
The Nilgiris and S. Wynaad..	1,200 mostly in coffee (Para chiefly)
Malabar and S. Wynaad	400 (Para, Castilloa and Ceara)
Coimbatore	1,100 (Para)
Cochin	1,000 ,,
Travancore	6,000 ,,
Shevaroy Hills	1,200 (mostly Para in coffee)
Pulneys	100
Mysore	—
Coorg	2,000 (chiefly Ceara)

Since the above statement was made several companies have commenced active operations in the Travancore district and also in Burma, and we may soon expect to see, in Southern India and Burma, about 20,000 to 30,000 acres of planted rubber.

Ceylon.—The island of Ceylon has evinced considerable activity in the planting of rubber trees, as the following figures will indicate:—

Year.	Acreage.	Year.	Acreage.
1898 ..	750	1903 ..	7,500
1899 ..	1,250	1904 ..	11,000
1900 ..	1,750	1905 ..	40,000
1901 ..	2,500	1906 ..	100,000
1902 ..	4,590	1907 ..	130,000 (estimated.)

The importance of this acreage will be manifest when it is remembered that that under tea, which has been long established in Ceylon, is only 382,000 acres, and that under cacao 34,000 acres.

Malaya.—In the Federated Malay States a total of 150,000 acres has been reported as alienated for this product. According to Carruthers, the following is the estimated average for the middle of 1906 in the Federated Malay States:—

Under one year old		25,000 acres.
One year and under two years old		15,000 ,,
Under three	,,	4,500 ,,
Under four	,,	4,000 ,,
Under five	,,	8,500 ,,

Other authorities estimate that in Malaya, Malacca, Sumatra, &c., there were at the end of 1906 about 90,000 acres planted; in Java about 40,000 acres; and in Borneo about 12,000 acres. Before very long we hope to be able to state definitely that in the Indo-

Malayan region alone there are one-quarter million acres of planted rubber trees, mainly of *Hevea brasiliensis*.

Planting of Rubber Trees.

A very responsible journal, viewing the probable future developments less than two years ago, predicted that by the end of 1906 there would be planted in the East about 100,000 acres of rubber trees, and suggested that an average yearly increase to the plantation rubber acreage in the East might be taken in round figures at 20,000 acres. But it is obvious from previous considerations that there are now nearly one-quarter of a million acres, and the propositions now being considered in London alone suggest that during the next few years the annual increase in planted acreage is likely to be on a very large scale especially in Ceylon, Malaya, Borneo, Java, and Sumatra.

Thousands of acres have been planted during the last two years, and the progress of events in Ceylon is of interest, since we have seen that that island, by its phenomenal activity, has planted more since the beginning of 1905 than it did in the whole of the previous twenty years, though seeds were then available.

The recent activity in Ceylon has placed that small island, as far as insular plantation acreage is concerned, in the first position in the British Empire, but how long it will hold that position it is difficult to foresee. Furthermore, Ceylon doubled its rubber production in 1906 over 1905, the amount produced, less that re-exported from the Straits and China, being approximately 140 tons.

Importance of Plantation Supplies.

The future importance of plantation rubber is one which cannot be neglected, especially in view of the enquiries regarding the supplanting of wild rubber by that from plantations. There can be no doubt about the question of economy in the two classes: very many of the wild-rubber areas in Africa and America are now being gradually transformed into plantations of some kind or other. The general tendency of present-day operations is to lead to an extension of regularly-planted estates where wild-rubber forests or ordinary forests previously existed and a reduction of genuine wild-rubber areas; in view of these facts it seems desirable to determine the equivalent of the wild areas now exploited in terms of plantation acreage. Assuming that the consumption for 1906 was 65,000 tons, what plantation acreage would be required to supply that amount? During 1905 and 1906 the trees on plantations in Ceylon, Federated Malay States, Straits Settlements, and parts of Southern India gave an average annual yield of 1 to 1½ lb. of dry pure rubber per tree. If you take the minimum yield of ¾ lb. per tree per year, from estates planted twenty by fifteen feet apart, the yield per acre is at the rate of one ton of pure rubber per twenty acres; if you allow at the rate of 1½ lb. per tree, which is by no means excessive where labour for tapping is available, you have one ton of rubber per year from every block of ten acres. The 65,000 tons of wild rubber supposed to have been consumed in 1906 may be roughly estimated to have contained about 20 per cent. of impurities, so that its equivalent in pure plantation rubber would be about 52,000 tons; to produce this amount you would require 1,040,000 acres on the minimum estimate, or 520,000 acres only on the estimate of 1½ lb. of pure rubber per tree. You will see from the figures given elsewhere that the plantation acreage in the Indo-Malayan region alone already promises to be not not much less than 250,000 acres.

Those calculations give you some idea of the position of the present plantation acreage in the East in relation to last year's consumption. But it may be logically stated that this is a false standpoint to argue from, since the trees on the land alienated for rubber to-day will not be in bearing for many years to come, and in that interval the consumption will at least show the normal yearly increase; these are contentions which cannot be negatived. If you assume that the world's consumption will increase at the rate of only 5,000 tons per annum, and that the output from wild sources will remain constant at about 60,000 tons per year, you may still require in 1913 no less than 640,000 acres of cultivated plantations to supply the material above that produced from wild sources. It is fairly safe to reckon that 80,000 additional plantation acres will be required every year to supply the annual incremental increase in consumption of 5,000 tons of wild rubber. It is believed that more than that amount will be planted yearly, and, therefore, that plantation rubber will sooner or later obtain a prominent, if not the commanding, position as a source of future rubber.

Plantation and Wild Rubber Supplies.

In the past, wild rubber has controlled the market of the world, and must continue to

be of ruling importance during the next few years. There are a few people who believe that it will always occupy a dominant position, and that plantation rubber can never do more than supply a small fraction of the yearly incremental increase which manufacturers demand. The exact position of the wild, plantation, and what may perhaps be termed the pseudo-wild rubber supplies in the British Empire, and in islands and territories belonging to other nations, is difficult to ascertain, but I think it can be shown that in a very small fraction of the Indo-Malayan region, to say nothing of our West Indian islands or of the vast African territory, we are preparing to take an important and perhaps predominant position as producers of rubber from organized and well-kept tropical plantations. We have more than sufficient land available in the tropics to supply double or treble the amount of the world's consumption for 1906, and can already—barring unforeseen disaster—promise to supply from 12,000 to 25,000 tons of pure rubber from the acreages now planted in Ceylon, Federated Malay States, Borneo, South India, Java, and adjacent islands. The position is so strong and promising that one may be excused for believing that if the extension in rubber cultivation continues as it has done for the last few years, the ultimate condition of low prices and abundant production is not far distant; such changes will, however, be of much benefit to the industry. Wherever you go in the countries just mentioned, the one great topic which is commanding attention, energy, and capital, is that of the cultivation of rubber-producing trees, and but few other products can, in the tropics, hope to receive the consideration they deserve, until the rubber craze has been satisfied. The plantation rubber industry in the East has already made a good name, and no one who possesses an intimate knowledge of the present position and probable future developments, can deny that it has gone to stay. The success which has attended many ventures has arrested the attention of responsible officers in all parts of the world, and it will interest you to learn that thousands of seeds of *Hevea brasiliensis* were sent back to Brazil, from Ceylon, for planting purposes, during 1906, in addition to very large numbers of seeds and plants to Africa, West Indies, Borneo, Sumatra, Java, and parts of India, &c.

During my short stay in England, I have had the pleasure of meeting several rubber manufacturers, and my confidence in the plantation industry has been increased in consequence of the information they have given me, and their willingness to book forward contracts for the next ten years, at prices which will well repay the cultivators in the tropics.

Future Plantation Output.

Up to the present the cultivated trees have not supplied much rubber, but it is necessary to point out that five years ago this cultivation was not favourably viewed, and it is only in the last few years that the acreage has increased by leaps and bounds, out of all proportion to the gradual development of more remote years. We have seen that in Ceylon, from 1890 to 1898, the acreage only increased at the rate of about 50 acres per year, and in 1898 was estimated at approximately 750 acres; three years later rubber was planted on 2,500 acres, in 1904 it occupied 11,000 acres, in 1905, 40,000 acres, and last year, 100,000 acres; and similarly in other Eastern possessions. I again mention these figures to draw attention to the fact that the planting of rubber trees during the last two years in the Indo-Malayan region alone has been on a comparatively large scale, and that we may therefore expect to see a sudden increase in the amount of rubber on our markets a few years hence. Ceylon alone has already planted land sufficient to supply London with about 7,000 tons of rubber per year in place of the 70 tons she sent in 1905: land is being applied for and purchased at very high prices, and very soon a prominent and permanent position will be established. When one considers what has recently happened in Ceylon, the Federated Malay States, and India, it is obvious that the export in a few years will be as suddenly increased as has the planted acreage in these places, and for this we must be prepared.

Purity and Constancy of Plantation Rubber.

One of the outstanding features of the future plantation rubber industry will be its constancy, not only in output but in purity, and also probably in form and physical property. The acreage of each estate is usually well known, and the accuracy of the output per year will be guaranteed just as it is on mature estates of other products in the tropics. The consumers may rest assured that adulteration will never be adopted, first because there are no trees of such yielding capacity as those under cultivation, and secondly because the estates are mainly under the supervision of

Europeans who are only too anxious to establish a fair name for their produce; any changes in chemical and physical properties which may occur in the rubber exported in the future will either be due to a change in the mode of manufacture or to the increasing age of the tapped trees—two possibilities which suggest improvement rather than retrograde development. It is almost certain that the form of the future rubber will be one which will minimise the liability to oxidation and development of tackiness in transit, and one which will commend itself for ease in handling and shipment.

Improvements in physical properties are to be expected year by year as the trees grow older; what Europe and America are receiving to-day from plantations are only the worst and most crude samples of rubber, for the planters do not know what is really required—the industry is in its elementary stage, and all may rest assured that no efforts or expenditure will be spared which will help to place the cultivation of rubber trees on a sound basis.

Rubber Consumers and Producers.

There is one point which, while dealing with plantation rubber, I cannot omit to mention. I refer to the want of unanimity between producers in the tropics and consumers in Europe and America, to the lack of authoritative information from consumers as to what they wish their colonial producers to turn out. Planters in Ceylon, India, and the Federated Malay States, are very anxious to find out what form of preparation the manufacturers most desire, and the fact that within twelve months they have sent home their plantation rubber in the form of biscuits, sheets, crêpe, lace, flake, ribbons, balls, block, pressed scrap, washed scrap, hand-picked scrap, in the smoked and unsmoked condition, dry and wet, naturally and chemically coagulated, and in many other forms and conditions should be sufficient to indicate the manner in which they are endeavouring to meet whatever requirements may be stipulated. The producers desire to adopt methods which will enable them to dispose of the large volumes of latex speedily and to pack and ship the rubber with the greatest security and ease.

Will the manufacturers be good enough to state whether they prefer rubber which has not been obtained by the use of chemical re-agents, or if they object to the washing of the freshly-coagulated material? We should also like to know if they prefer to receive it free from moisture, in the smoked or antiseptic form, and whether they prefer rectangular thin sheets, thick blocks or biscuits. A definite statement from the consumers would be heartily welcomed by the producers, it would obviate much waste of time and money, and lead to the establishment of definite standards for exports at an early date.

Effect of Rubber on other Cultivations.

The planting of rubber trees necessitates the destruction of the original forests, but sooner or later a new forest takes the place of the old. The cultivation of rubber vines (*Landolphia*) does not incur the destruction, but demands the retention of a part of the original forests, as the vines must have some means of support, such as stems along which they can climb. Rubber cultivation is therefore fundamentally different from that of tea, cotton, camphor, &c., and in many cases leads to the re-afforestation of lands which have been allowed to lapse into waste compounds or chena land.

The extensive cultivation of rubber trees will directly affect many other products cultivated in the tropics. At the present time *Hevea brasiliensis* is being largely planted among tea in Ceylon and South India, among coffee in Sumatra, Java, and South India, and among cacao in Ceylon. *Castilloa elastica* is being extensively grown with cacao in the West Indies, and to a small extent in Ceylon. *Ficus elastica* is grown with coffee in Sumatra. The distance of the rubber trees from one another is generally such that the intercrop of tea, coffee, and camphor will ultimately be choked out, and only in the case of cacao does the combined cultivation appear to be of a more or less permanent character. Furthermore, there are vast areas in the Federated Malay States where cassava or tapioca and gambia are grown on the land as soon as the jungle has been felled and cleared. In Ceylon, minor crops of chillies, hill paddy, bananas, tapioca, lemon grass, and citronella are cultivated; in other countries, tobacco, indian corn, and other plants are grown on new land. These areas are now being rapidly interplanted with rubber trees which, once they have reached maturity, will not permit of the cultivation of the intercrops and catch crops, which are of such importance to natives and commerce generally. In some countries, where the faith in rubber alone has not yet taken a very firm position, the majority

of the lands already under other products, are being interplanted with rubber species.

In Ceylon, during the last few years, a large area of the poorer low-country tea has been interplanted with *Hevea brasiliensis*, and there can be no doubt that in three to five years time the greater part of such tea will no longer be plucked; the same may be said of much coffee in Southern India, and in various Indo-Malayan regions. Now, however, the tendency appears to be to plant *Hevea brasiliensis* as a single product, when land is available. Though this is the case with tea and coffee, the effect on cacao in Ceylon appears to be the reverse. In the Matale, Dumbara, Kurunegalle, and other districts of Ceylon, *Hevea brasiliensis* and cacao (or cocoa) are being largely planted on new clearings as a combined cultivation; the plants are generally distanced so that there are about 100 rubber and 100 cacao plants per acre; under such conditions, both appear to thrive for many years, and to yield fair harvests in the fifth or sixth years.

Land planted in coconuts is usually not interplanted with rubber plants, though in one country coconuts have been felled and removed to make room for the rubber trees.

Camphor as an intercrop among rubber is, in the tropical parts of the British Empire, as yet only in the experimental stage.

To sum up the effect of the combined cultivation, we may say that much tea and coffee will be killed out, the acreage in cacao increased, and the available land for catch crops of oil grasses, bananas, chillies, &c., be ultimately permanently reduced.

Laticiferous and Caoutchouc Plants.

It is necessary to explain that numerous plants possess latex in large quantities, but the viscous liquid is often almost useless on account of the low percentage of caoutchouc or the high percentages of albuminous, resinous, and other substances present. Everyone must have noticed the milky liquid which issues from the cut surfaces of *Sonchus arvensis* and species of *Euphorbia* plants which occur abundantly in parts of England; in the tropics there are many plants, such as species of *Carissa* and *Plumeria*, *Euphorbia Tirucalli*, *E. Antiquorum*; climbers or lianes, *Cryptostegia grandiflora*, *Willughbeia zeylanica*, which almost squirt out large quantities of latex when cut with a knife. The same may be said of *Palaquium* and *Bassia* in Ceylon—genera from which the gutta percha of commerce is obtained, but which in the island mentioned yield latex of very little commercial value. The latices of importance usually possess high percentages of caoutchouc—the compound which largely determines the uses to which the dried product can be put. "If one considers species of the same genus, the striking fact is revealed that the chemical composition of the latex is almost of specific importance. There are many species of *Hevea*, *Landolphia*, *Ficus*, and *Funtumia*, but only certain members possess high percentages of caoutchouc and low percentages of resins and proteids.

The Laticiferous System.

All the species which have been previously mentioned are characterised by systems of sacs, series of cells, or tubes containing latex; these occur in nearly all parts of the plant. The commercial possibilities and the ultimate success of several species are determined by the particular type of laticiferous tissue which each contains; each type requires to be dealt with in a particular manner: it is very dangerous to adopt the same methods of tapping for all species. The principles of paring and pricking the primary and renewed cortex should be studied more seriously and intelligently than they appear to be at the present time. When one considers the great difference in the nature, mode of origin, and development of the laticifers in various plants, there is every reason for suggesting that each species should be tapped on a particular system in order to take advantage of the peculiarities of each type. These remarks are made because there is a tendency among responsible persons to recommend or adopt for their *Castilloa*, *Manihot*, *Funtumia*, *Landolphia*, and *Ficus*, plants, the system of tapping which has been found to be so successful with *Hevea brasiliensis*. From a study of the laticiferous system of our prominent plants, I am convinced that in certain instances the old native, and apparently wasteful, methods adopted in the extraction of latex are probably as good as, and even better than, many which have been evolved.

The laticiferous system in several of our important species occurs in the cortex of the stem, branches, roots, and in the leaves, flowers, and fruits. In some species the laticifers appear to be best developed in the root, and the extraction of latex is only considered in relation to that part; in other species there appears to be a better develop-

ment in the stem, and in a few others the flowers or young twigs show conspicuous developments. Generally, these structures and the latex appear in the embryo and remain until the death of the plant; in some cases, however, the laticifers are not obvious except in plants of some years' growth. Sometimes they are absolutely restricted to stem and roots, the leaves and flowers never being in possession of such structures; in a few cases they appear in the young tissues, and then gradually die and disappear.

For the purposes of this paper it will perhaps be sufficient to state that there are three types of laticiferous systems, the components of which are scattered freely throughout the cortex in the stem; they may, according to their age and the condition of the plant, be partially or wholly filled with latex. When the cortex is incised the latex escapes, the quantity thus issuing depending largely upon the structural relations of the laticifers and the moisture conditions. A given incision allows the latex to issue only from a local area, dependent in extent upon the nature of the laticiferous system being tapped; generally several, and sometimes a very large number of, incisions may be made on the basal part of the stem.

Collecting Latex.

The latex is usually obtained by making incisions in the cortex of the living plant, and placing receptacles beneath each incision or groups of incisions; this method is in use in the extraction from tree forms, such as *Hevea*, *Castilloa*, and *Funtumia*, and also from some vines of the *Landolphia* type. When the plants are small (*Parthenium argentatum*), or when the latex is concentrated in the roots (*Landolphia Thollonii*), the latex is not usually extracted as such, but is allowed to dry within the plant tissues; the residual rubber is obtained therefrom by a process of steeping and softening the tissues in water or certain solutions, and subsequent maceration. A sample of *Landolphia* rubber thus prepared has been kindly sent by Mr. Johnston for your inspection.

In collecting the latex from living trees, several systems are in vogue. In some parts of Africa and America, the natives fell the trees, and after having placed the trunk in a proper position, ring it at definite intervals along the length of the stem; they then collect the latex issuing from each cut in a receptacle made of leaves or some other convenient or common article. The more intelligent natives make incisions in the basal part of the stem with a heavy hatchet, or large knife, and allow the trees to remain standing in order that at some subsequent date they may be again tapped. In some parts of Mexico, the natives appear to believe more in the tapping of the higher parts of the Castilloa trees; an illustration showing a Mexican at work, is shown on the screen. In some parts of Mexico, even skilled Europeans appear to have recourse to the use of large unwieldly knives with which a heavy blow may be inflicted. Apparently the methods adopted in the collecting of wild rubber are not based on the preservation of the trees or vines, and even when the exploited forests are under skilled supervision the bark is often severely bruised and the cambium layer more or less destroyed in local areas; the object in both cases appears to be the extraction of as much latex as possible from each tree in a single day or with the minimum expenditure of labour.

Methods on Eastern Plantations.

On the other hand there can be no doubt that the rubber planters on Eastern estates, whose work is being closely followed and minutely imitated by visitors from many parts of the world, are striving to obtain satisfactory yields of latex by systems which allow the trees to remain in a healthy and vigorous state. The labour conditions prevailing in our Eastern possessions are such that very careful work can be cheaply done. The fact that each coolie is provided with paring and pricking knives and is capable of effectively tapping 40 to 200 trees as his daily task, is sufficient to indicate the shortness of the duration of the daily tapping operation on each tree. In the jungles possessing indigenous wild and scattered trees it is often impossible for the coolie even to walk the distance separating ten or twenty scattered rubber trees as a daily task; consequently, when a wild rubber tree is found the coolie does not lose sight of it until he has extracted the maximum amount of latex from it.

On Eastern plantations the objects are (1) to treat the trees very lightly each day; (2) to irritate only the first five or six feet from the base; (3) to avoid too rapid excision of the bark; and (4) to obtain the latex from the innermost and more abundant laticiferous channels without unduly damaging the cambium or healing layer of the stem.

Systems of Tapping.

The systems of tapping now in vogue are numerous; they include the ordinary and basal V, inverted V, single oblique, half herring-bone, full herring-bone, half-spiral, and full spiral systems. The lines in each system usually incline at an angle of 30 to 45 degrees, and are distanced approximately twelve inches apart. Most of these systems are planned out on several or four sides of each tree, and one part or side is tapped on successive days; the full spiral system is the only one which completely taps the whole of the cortex. When the tapping areas, on each of the four sides of a tree, are disposed so as to face north, south, east, and west, compass tapping is often adopted. On badly tapped trees, or those with irregular gnarled surfaces, a zigzag system is necessary in order to secure a gradual slope of each line between the knots. The V system was largely adopted in the early days, and is among one of the oldest known; the inverted V, basal V, and the full spiral systems are the most recent; the half or full herring-bone principle appears to be more frequently adopted than any other system. The full spiral system gives very large yields, but if the tapping is carried on too rapidly it may endanger the health of the tree, and involve considerable waste of cortical tissues.

Frequency of Tapping.

The frequency of tapping operations is generally largely determined by the labour and supervision available, and as far as *Hevea brasiliensis* is concerned the greatest fear is that when once the large acreages are in bearing there may be some difficulty in obtaining the labour necessary to take full advantage of the yielding capabilities of the trees. The illustrations show the condition of the trees after they have been tapped every day, every alternate day, twice per week, once per week, once per month, and so on, for a period of eleven months. It is a curious fact that tapping every day may give lower yields than tapping every alternate day on account of the too rapid excision of the cortical tissues wherein the laticiferous channels develop day by day. The following are some of the results obtained up to the time of my departure from Ceylon, in January last, at the Henaratgoda Garden. There were five trees of *Hevea brasiliensis* in each group, and all were tapped on the full spiral system; the trees were alternately pared and pricked during the period under experiment, and were twenty-nine to thirty years old:—

Frequency of Tapping.	Number of times tapped.	Yield of dry rubber, per tree. lb.	oz.
Every day	354	12	8
Every alternate day	177	14	3
Once per week	64	6	1
Once per month	15	0	12

The tapping operations were carried out during ordinary working days, excepting Sundays and times of flood, &c., in order to make the results applicable, as far as possible, to the conditions obtaining on the average rubber estate. The tapping of the trees in the first two groups — every day and every alternate day — was suspended for a short period, but the trees in the other groups were tapped for fifteen months. These results should only be viewed in a very general manner, but the danger of too frequent tapping is manifest from the above series.

The frequency of tapping should theoretically be determined by the wound response and ease of the flow of latex, but practically a system must be devised which, while it may involve a little waste of cortical tissue, will allow one to employ the labour on estates regularly, and thus obviate a greater waste of expenditure or general disorganisation. Though the proprietors of several rubber plantations are fully aware of the value of periodicity in tapping, they are compelled to adopt methods absolutely opposed to all plant requirements, and some anticipate only being able to tap sections of their properties in successive years, instead of each tree every alternate day.

Frequency and Response.

Regarding this subject of frequency or periodicity in tapping it is interesting to recall the results of certain experiments with *Hevea brasiliensis* and *Manihot Glaziovii*. When *Hevea brasiliensis* is first tapped the flow of latex is often insignificant, but on re-tapping in approximately the same area it is noticed that the yield of latex gradually increases until the maximum is reached. This was, as far as my knowledge goes, first clearly determined by Parkin, in Ceylon, and has been since confirmed in Java by Dr. Tromp de Haas, and by Mr. Stanley Arden, in the Federated Malay States. This wound response in *Hevea brasiliensis* is explainable if we imagine that repetitional tapping or irrita-

tion in the same area leads to a distended condition of the latex tubes which, being in communication with neighbouring channels of the laticiferous system, become charged to their maximum extent and consequently give a higher latex yield. The wound response is obvious after 24 hours, and may become more pronounced day by day until the maximum may, according to Parkin, be reached on the 14th day. When the laticiferous channels have been drained of their contents an interval of time must elapse before they can be expected to yield the largest quantities of latex. The same experiments have been made with some twenty-year-old trees of *Manihot Glaziovii*, but have not been accompanied by the same results.

Coagulation.

The latex obtained from the plants is rarely exported as such; it is usually subjected to some treatment which ensures the removal of the greater part of the water. The methods employed in different parts of the world show a great variation, and are often founded on opposing principles. Most of the processes in vogue at the present time involve chemical changes of certain original constituents of the latex, a few enable the operator to separate the caoutchouc by mechanical means—in which cases chemical changes are either entirely stopped, or only allowed to continue for a short time.

The fresh latices may be neutral, acid, or alkaline in reaction; they consist essentially of a liquid in which caoutchouc and other globules are held in suspension, and other substances in solution. When latex has been coagulated, the caoutchouc globules form an irregular but connected network which encloses certain resinous and albuminous matter; by the contraction of the caoutchouc the water with some of its dissolved substances is expelled.

Coagulation often takes place as soon as the latex is exposed to air; other latices will remain much in the original condition for several days. Latices, which are liable to undergo putrefactive changes on exposure to air, may sometimes be prevented from coagulating by the addition of formal, which prevents decomposition, or by the addition of ammonia which neutralizes the acids as soon as they are produced. In the simplest cases, coagulation is effected by allowing the latex to stand in circular or rectangular receptacles until decomposition sets in and a strong acidity is developed; sometimes the caoutchouc globules, owing to their being lighter than water, can be separated from the other constituents by centrifugal machines; the addition of water alone, or of aqueous solutions of heavy sodium salts, is often sufficient to cause the light globules of caoutchouc to rise to the surface. Some latices can be coagulated by boiling, or by the application of heat. In many cases, however, the latices are treated with chemical re-agents of an acid, alkaline, or alcoholic nature, or with acid and alkaline plant juices. The Amazon method of preparing fine hard Para rubber from the latex of *Hevea brasiliensis*, partly depends for its success on each thin particle of rubber being impregnated with small quantities of acetic acid and creosote. On plantations of *Hevea brasiliensis* small quantities of acetic acid are used to hasten coagulation, and the use of coagulating reagents possessing antiseptic properties is also receiving much attention in the East.

It is impossible in one paper to give the details of the operations which are being carried out in the preparation of rubber from latex in all parts of the tropics. This has been dealt with elsewhere.* It is sufficient to know that the latex can usually be rapidly converted into rubber ready for export. Most of the wild rubber arrives in Europe in a very wet state, but that from plantations is usually nearly dry; the former condition leads to a wavering in the price of the raw material, since the water contents are liable to great variation. The wild rubber, as you can see by the specimens on exhibition to-day, arrives in many forms, but that from plantations in the East is usually in the form of crêpe, sheet, block or biscuit, and of a high standard of purity.

Yields.

The yield of rubber obtainable from the different species under cultivation is a subject about which much has been said: it is on this factor that the success of the rubber industry rests. It is perhaps too early to make any definite statements on this subject, especially with reference to the yield obtainable from wild trees and vines of doubtful age, and growing under conditions the significance of which is but little understood. An annual yield of one pound of dry rubber per tree is, perhaps, above the average for plantation trees of *Manihot* and *Castilloa*; a yield of

* See "*Hevea brasiliensis*; its botany, cultivation, chemistry, and diseases:" Messrs. A. M. and J. Ferguson, Colombo, 1906.

two pounds per tree has been reported for trees of *Funtumia elastica* in the wild state, and annual yields of a few ounces, per vine, for certain wild *Landolphia* plants have been estimated. We have, fortunately, some information regarding the yields obtainable from trees of *Hevea brasiliensis* on Eastern plantations. Generally, the maximum yields of rubber are obtained during the first series of tappings; subsequent tappings may give poorer yields, though each tapping operation involves an equal excision of the bark. It will be quite obvious that the very best results with the minimum waste of cortex and of labour will be accomplished by taking full advantage of what may, perhaps, be termed the replenishing periodicity of the laticiferous channels. The results show that to tap too frequently may not only lead to a great waste of money in labour expenditure, but actually to a reduction in the total amount of rubber obtainable from the tapped trees; they further show that by tapping at certain intervals and allowing certain periods of rest very large quantities of latex, with very little expenditure of cortex or coolie labour, may be obtained. The best periodicities have not yet been determined, but sufficient has been said to indicate that such exist and deserve every consideration; all that can be said at present is (1) it may be dangerous to tap every day throughout the year; (2) tapping on alternate days throughout the year may give higher total yields per tree than tapping every day; (3) tapping the same area from 3 to 14 days in succession, in the case of *Hevea brasiliensis*, considerably depletes the laticiferous system; (4) tapping the same area daily for two or three weeks in succession partially depletes the laticiferous system of *Manihot Glaziovii*, and a rest must be given or fresh areas tapped. The results at present available indicate how valuable economic botanical investigations in the tropics may be to cultivators, and though it may not be commercially possible to conduct operations exactly which appear to be desirable from the purely scientific standpoint, yet I feel sure that the principles will ultimately, either partially or wholly, become an integral part of the daily operations on the best conducted plantations.

Future Yields from renewed Cortex.

The yields with which we have previously dealt, and on which the hopes of the future have been largely based, have been obtained by tapping the original coxtex; success in the future depends, however, on the yields obtainable from the renewed bark. In the more modern and systematic methods of tapping it is customary to repeatedly pare the lower surface of each sloping cut until nearly the whole of the original cortex has been excised. The innermost part of the cortex and the cambium are not intentionally excised; the cambium layer, by the division of its cells, gradually produces new cortical tissue from within outwards; sometimes when the cambium has been severely damaged new cortical tissue is produced from above downwards, in a conspicuous manner, and the addition of new cells from within outwards, only occurs when the injured region has been completely repaired. On some estates the cortical stripping round the whole of the tree has been effected in one year, and fair yields have been obtained from renewed cortical tissue which was only one year old. It has been demonstrated, however, that tapping young renewed bark is not always advisable; normal latex possesses about 50 to 60 per cent. of water, but that from renewed bark, only one year old, may under certain conditions possess as much as 90 per cent. of water and very little caoutchouc; furthermore, too frequent paring of the cortex will impair the vigour of the tree, and may result in early decay and death. At the present time the cortical tissues are removed at different rates, many planters cutting away the whole of the tissue between the parallel tapping lines, originally distanced twelve inches apart, in one year. It has been shown, however, that a tree may be pricked and pared on about ninety occasions in one year, and yet only three out of the twelve inches of bark between parallel cuts be removed.

Tapping at the rate of three inches per year, even on the full spiral system, a period of four years would elapse before the whole of the original cortex would be removed; this would allow a sufficiently long period for the new cortex to mature. If this is adopted a continuance of satisfactory yields may be expected; if it is not carried out, one can only expect a latex rich in water, and inferior, if not dead, trees.

Yields from Young and Old Trees.

The main factor on which the rubber industry depends is the yield of rubber obtainable, and the period over which it can be guaranteed. It is satisfactory to be able to state that the yields already obtained from Para trees varying

in age from 4 to 30 years are such that the industry may be expected to be able to withstand a very serious reduction in the price paid for the raw material. The cultivated trees can be first tapped when they have a circumference of twenty inches a yard from the ground, and may be tapped more or less continuously for the rest of their lives. Young trees are known which in the first year of careful and light tapping have given 4 to 16 ounces of dry rubber; trees from six to thirteen years old have given 2 lb. of rubber in one year, others eight to fifteen years have given 3 lb. in one year, and some of the very oldest trees at Henaratgoda have yielded as much as 15 lb. of rubber in eleven months. Naturally, the yield varies according to the system of tapping adopted—whether by the V, spiral, or herring-bone, &c., or whether paring or paring and pricking are adopted; it also varies according to the age and vigour of the trees and the part of the stem tapped. Generally, only the first five or six feet from the base is tapped, but on several estates where labour is plentiful and a few old Para trees exist, the latex is collected from the base up to ten, fifteen, and twenty feet. In the year 1905, a certain 198,000 trees, varying in age from four to twenty years, but mainly six to nine years old, were tapped and gave 246,800 lb. of rubber, or over one lb. per tree per year. In 1906, from the figures already available, this return is likely to show a good increase. From these and other considerations an average annual yield ranging from one to three lb. of rubber from mature trees appears possible, providing the constitution of the plant is understood and tapping operations are carried out in a scientific manner.

The outturn per acre can, of course, be easily calculated, and a Table is here given showing the output according to the distance the trees are planted and the yield obtained:—

Approximate Yield per Acre.

Distance.	Number of trees per acre.	¾-lb. per tree.	1-lb. per tree.	1½-lb. per tree.	2-lb. per tree.	3-lb. per tree.
(feet.)		lb.	lb.	lb.	lb.	lb.
10 × 10	435	326	435	652	870	1,305
10 × 15	290	217	290	435	580	870
15 × 15	193	145	193	289	386	579
15 × 20	145	109	145	217	290	435
20 × 20	109	82	109	163	218	327
20 × 25	87	65	87	130	174	261
25 × 25	70	52	70	105	140	210

Exceptional Yields.

The reports of yields which have been obtained from trees of *Hevea brasiliensis* in Ceylon and the Federated Malay States have been discredited, especially by persons who have been tapping trees other than *Hevea*. In my opinion no records which I have seen have depicted impossible yields, and knowing from experience the yield of rubber obtainable per unit of excised bark by all the systems of tapping, and from various sections of the stem, I feel inclined to the hope that once we understand our plants, much better average yields may be obtained. The largest yield which I obtained in Ceylon was 15 lb. of rubber from one tree 29 to 30 years old, in 11 months; it was my belief, confirmed by a few score men of experience who visited the tapped trees at Henaratgoda, that it would have been easily possible, at the sacrifice of the tree, to obtain three times the amount from the specimen in question.

Yield According to System.

It is necessary to point out that the yields procurable by the full spiral system represent those obtainable when the cortex around the whole of the stem is tapped; on the other hand, the yields for other systems usually represent those derived from a fraction or one side only of each tree, and are such that they may be expected to be more continuous over successive periods when the alternative sides are tapped in turn. On the herring-bone system, for instance, one out of four available sides may be tapped for one year and the other sides tapped in successive years. It is unnecessary to give the yields obtained by each system and per unit of excised bark, as these have been published elsewhere.

Latex from Different Sections.

Some laticiferous plants yield rubber of good quality when quite young, but this cannot be said of the *Hevea*, *Castilloa* or *Manihot* species in Ceylon. The cortex of the seedling of *Hevea brasiliensis* and the cotyledons of the seed itself possess a large number of laticiferous channels, but the latex obtainable therefrom is usually very sticky and the dried product of low commercial value. Rubber prepared from two-year-old trees of *Hevea brasiliensis* is sticky and easily snaps when lightly stretched; that from four-year-old trees or from stems which have a circumference of about twenty inches, though it does not possess the properties which

manufacturers most desire, realises a price which is, to the producers, satisfactory. When a tree is tapped for the first time, though it may be 4 or 29 years old, the rubber obtained from the latex is apt to turn soft, sticky, or tacky on keeping; this is usually accounted for by the large proportion of sap contents which are unavoidably mixed with the latex when the original incisions are made, the sugars, gums, &c., from the cortical cells providing a good food supply for bacteria responsible for the development of tackiness in rubber. Subsequent tappings of trees of these dimensions usually give good rubber when the tapping operations are carried out on the basal part (base to 5 or 6 feet); it is curious, however, to note that when the higher parts of old trees are tapped the latex obtained is often changed in constitution. The latex from high parts is often very watery, and possesses a low percentage of caoutchouc; on treatment with the requisite quantity of acid, coagulation does not take place; even when allowed to stand for several days a curdled liquid only is obtained, the particles of which are not elastic and do not adhere to one another.

Height of Tapping Area.	Number of times tapped.	Number of times when latex not coagulable.	Per cent. of tappings giving non-coagualable latex.
Base to 5 or 6 feet..	1,165	9	0·77
„ 6 to 16 feet..	95	1	1·05
„ 10 to 20 feet..	94	1	1·06
„ 20 to 30 feet..	94	2	2·12
„ 30 feet	171	24	14·03
„ 50 feet	84	5	5·95

The number of times when non-coagulable latex has been obtained from various sections of the stems of 29-year-old trees is given in the table, and in considering them one should remember that the circumference of the stems at the highest points tapped was not less than 30 inches.

Labour and Yields on Small and Large Plantations.

Owing to the co-operation and courtesy of the planting community in Ceylon, South India, and Malaya, I have been able to collect a considerable number of figures showing the yields on small and large properties for a few years in succession, and am enabled to bring a few general conclusions before you to-day. The most important fact which I wish to mention is that the yields obtained from the same trees in successive years have shown a slight increase; this is especially true in those cases where the tapping operations have not led to too rapid excision of the cortex. But though this is correct for small and some large estates, and though certain small properties have shown a very large increase per tree, yet the yield per acre on some plantations possessing a very large number of mature trees has shown a reduction. The cause for this reduction is that a large acreage has been tapped whenever labour permitted; sometimes only sections of the estates have been tapped, and in such instances each tree has not received the attention which those on smaller properties have. Sound trees of *Hevea brasiliensis* will stand tapping every alternate day throughout the greater part of the year, and while several friends assure me they are able to do this at present, others are equally emphatic on being unable to adopt such frequent tapping.

List of Samples of India Rubber, Collected by Messrs. Edward Till & Co., Exhibited at the Meeting.

Imperial Ethiopion Rubber Co.—

Sample of Vine rubber from Abyssinia, supposed to be "Landolphia Kirkii."

Exhibited by:—

Messrs. Lewis and Peat—

Samples of Plantation Rubber, in sheets, biscuits, crêpe, lace, &c., from Ceylon Estate.

Samples of Plantation Rubber from the West Indies, Assam, and Malaya.

Block of smoke-cured Biscuit Rubber from the Amazon.

Collection of Knives and Tools used in Rubber Industry.

Collection of Photographs illustrating Growth and Curing of Rubber in Ceylon and Brazil.

Messrs. Little and Johnson—

Collection of samples of rubber from the Congo State.

Messrs. Spence, Wallis and Co.—

Samples of Para biscuit, Ceylon rubber (Duckwari Estate).

Mr. Herbert Wright—

Samples of Latex from Ceylon with Coagulated Rubber from the same.

DISCUSSION.

The CHAIRMAN, in opening the discussion, after congratulating the author on the production of such a comprehensive paper, thought there was little to be said regarding the Manihot mentioned by Mr. Wright as cultivated in South America, which was not the same as Ceara rubber. It seemed to be well known in Saô Paulo, Southern Brazil, far to the south of Ceara, but it was not there considered to be the same as the Ceara rubber tree. Seeds of the same Manihot had been sent from Bahia, midway between Ceara and Saô Paulo. When sent from Bahia the seeds were termed Maniçoba, a name which was usually associated with the Ceara rubber tree *Manihot Glaziovii*. The use of the name Maniçoba at Bahia for that *Manihot* might mean that it was there thought to be the Ceara rubber tree. But it certainly was not *Manihot Glaziovii*, and it might be that in these two different Brazilian States the same name was applied indiscriminately to two different trees The botanical name of that species was not yet known; nor was it known how its rubber compared with that of *M. Glaziovii*. Those who recalled what happened in Ceylon, when leaf-disease attacked coffee, would ask whether rubber was necessarily exempt from the dangers to which other exotic crops were liable. People were more alive now to such possibilities than they were a generation ago; and it was now more generally recognised than it was, that what was spent in securing the services of good plant-pathologists was a sound form of insurance against such risks. Planters were now prepared to act, and act promptly, on lines laid down by competent advisers, should such a visitation occur. But in spite of all that was known, and could be done, there was even yet no absolute guarantee against sudden and overwhelming calamity. With regard to rubber such a visitation was not inevitable; considering the precautions that planters now took, it was perhaps unlikely. But it was not impossible. It had quite recently been reported that the cultivation of one particular rubber in Ceylon was impossible, owing to its liability to attack by an insect pest. Those who knew what had occurred in India since "synthetic" indigo first appeared into the market would equally ask whether rubber was necessarily safe against a like experience. The misgivings of some took the form of warm protests when the possibility was hinted at by their chemical brethren. It was not a foregone conclusion that chemistry would succeed in preparing artificial rubber on a commercial scale, nor was it certain that if "synthetic" rubber became an article of commerce "natural" rubber would cease to be required. But it was known that artificial rubber had actually been produced, and if the only instance of it so far recorded was in a sense accidental, one might be assured that chemistry would not rest content until that experience had been repeated, systematised, and if possible elaborated for commercial purposes. There was another risk which would be in the minds of all who were conversant with the story of cinchona cultivation in South-eastern Asia They might anticipate that if the extension of rubber cultivation continued as it had done for the last few years low prices and abundant production were not only possible but probable. The author had said that the change would be of much benefit to the industry. He (the Chairman) was connected for a considerable period with the cinchona industry, and his connection with that industry had been somewhat peculiar, because he had to act simultaneously in the three-fold capacity of planter, bark purchaser, and quinine maker. The question of benefit owing to low prices and abundant production he thus came to learn at first hand, was one that depended largely upon the point of view. The difficulty was that most movements were progressive, and it was not always easy to draw the line between abundant and superabundant production. There was, perhaps, less difficulty in drawing the line between prices that were not and prices that were too low. When that line required to be drawn, the producer had seriously to consider if it was worth his while to go on. That was a contingency that had to be kept in mind, and, in time, to be faced.

Mr. R. K. GRAY said the author had dealt in his paper with a subject which was of very great importance to many people in this country, but he agreed with the Chairman that it was necessary to give a warning in connection with it. Although he himself was a manufacturer, and would like to se

low prices, he did not like to see people get into too much of a fever when they had a good thing. He remembered some thirty or thirty-five years ago urging some friends of his in the East to go in for rubber planting, and he pointed out to them, what had been since proved to be correct, that rubber planting was not at all a question of planting trees but of organisation. When tea and coffee planting failed to be remunerative, proper organisation was instituted, and it was certainly to the credit of tea and coffee growers that they should have started a new production which was conferring and was going to confer in the future a very great benefit on the rubber industry. It was a very different thing, however, where people went into a business with a good organisation as the stand-by, and where others went into it purely because there was some ground to be bought and plants to be planted. He desired to draw attention to the point, because he was very much interested in the rubber industry, and he would not like to occur in the rubber planting industry what had happened in other industries with disastrous effects leading to a discrediting of perfectly legitimate and profitable undertakings. Very excellent business was to be done in rubber estates, but when these had to be sold to an investing public, organisation as well as ground and plants should be included in the bargain. Manufacturers who had been in the rubber business for many years did not go into the rubber-growing industry, not because they did not believe in it, but because they thought it was more an affair for the Government than for private individuals. It was interesting to hear, and he thought it was to the credit of this country, of the large extension of rubber planting that had taken place in the East, because he thought that the extension had been very largely due to the Department at Kew. Some people—he amongst them—were wont to criticise Governmental Departments in this country for wasting money; some Departments were always being pitched into, and it was a great pleasure to him to be able to say that the extension of the rubber industry abroad was in a large measure due to the Department at Kew. Those who read Mr. Wright's paper would find a great deal of instruction in it, and it was hardly possible to criticise what an authority like Mr. Wright had said.

Mr. Fritz Zorn thought the planters of Ceylon had always shown themselves great sportsmen in the way in which they had taken up rubber cultivation. because it was to be remembered that comparatively few years ago the men who started planting rubber were looked upon as visionaries and laughed at. He was very glad that a note of warning had been struck by the previous speaker because it was very necessary. At the present time some of the older rubber companies were showing the first fruits of their enterprise, two of the most mature companies having recently announced dividends for the year of 40 per cent.; but there was the danger that, with such large profits being shown, companies of a very different description might be placed before the investing public, and thus bring into disrepute an industry which ought to be a great one for those engaged in it. He thought it would also be of value if the author could state whether considerable danger might exist from the possible disease of the rubber plant. The question of the production of artificial rubber was one which might be easily exaggerated. Synthetic rubber must be produced at a price which would enable it to compete with plantation rubber, and he believed he was correct in saying that the latter, as it was grown now or would be grown in the course of a few years, could be produced at a cost roughly of 1s. a lb., so that unless artificial rubber could be made at a less price, the planter had nothing to fear. Another most important point was that, even if a completely satisfactory artificial rubber were made by chemists to-morrow, it would take a number of years to ascertain whether it possessed that most necessary quality of natural rubber, namely, durability. The archway under Euston Station was paved 18 years ago with a rubber composition, and during that time it had only worn to the small extent of five-eighths of an inch. It had been clearly demonstrated that, compared with wood, asphalte, and pavings of that description, rubber worked out much cheaper in the long run because of its enormous durability. If artificial rubber was produced, it would not be possible to demonstrate for many years whether it was durable, so that it would, therefore, only very slowly displace the natural article. The parallel employed by the Chairman with regard to cinchona and the fall in price was scarcely typical of rubber, for the reason that the latter was now standing at a remarkably high price compared with a few years ago; and if the price should fall from its present figure of 5s. to 4s. or 3s. 9d., there were many purposes for which rubber would be immediately employed for which, at its present price, it was far too expensive. If, on the other hand, cinchona bark were to fall very heavily in price, there were not many purposes for which it could be employed other than those for which it was already used; whereas, if the price of rubber fell, it could be used for road paving and numbers of things of that description. He knew that one leading manufacturer in the Midlands estimated that if rubber were to fall to 4s. a pound, the present consumption of about 65,000 tons per annum would be doubled, and if it fell to 3s. a pound it would be quadrupled. Those figures indicated that plantation rubber grown at a cost of 1s. a pound had not much to fear from over-production for many years to come.

Mr. H. Figgis deprecated the statement which had been made that if the price of rubber fell to 4s. a lb. a great enlargement of consumption would be likely to take place. He wished he had the manufacturer in the Midlands, to which the last speaker had referred, as his customer, because it w

not 20 years since he sold rubber at considerably less than half its present price. No such enlargement of the industry as had been suggested took place, although he was aware that the circumstances had now changed. The consumption had kept pace with the increase in supply; but the author was candid enough to say that, looking forward to the future, they must as sensible men expect a very large increase from the 250,000 acres in Malaya, India and other regions where plantations had taken place. He therefore thought it would be wise to bear in mind the warning which had been uttered, and not be too sanguine that the present prices would always continue. It would be within the recollection of many that cinchona once sold at 4s. a lb., and it had now come down to a penny and twopence simply because of over-production. He had been very much struck with the admirable quality of the rubber at present being supplied, and did not think it could, as a whole, be easily excelled. Very few parcels of biscuits or sheet had come over at all soft or sticky, and it was a marvellous thing to him that the planters in such a new industry were now able to send to this country such splendid specimens of pure, useful rubber. The author had suggested that planters would like to know how the manufacturers desired the rubber to be prepared, but personally he ventured to think planters would do well to remember that different manufacturers had different wants, and that it was undesirable to prepare the rubber in one uniform way. After a long and wide experience of rubber from all parts of the world, and having sold more rubber as a broker than probably any man living, he desired to say that the planters deserved the utmost praise for the way in which they prepared their product, and the beautiful way in which it was packed and sent to this country; and they were also thankful to Kew and the Colonial Office to a large extent, because it was owing to their efforts that the wonderful success which had been achieved by the industry was due.

Mr. HAMEL SMITH stated that in the West Indies it was found that the cacao estates, after about 25 years, were already beginning to fall off in their yield; but it seemed to him that if, as some people suggested, Castilloa was planted as a shade to cacao that falling away would take place at an even more rapid rate than it was doing where cacao was planted alone. He had been informed by a cacao planter that the output of cacao would also fall away owing to the exhaustion of the soil. It seemed to him that if rubber were planted with cacao, the advantage would be gained on the crop from the rubber tree as a shade tree; but if it tended to deteriorate and hasten the falling off in the crop, he thought the profit would in the long run be diminished rather than increased. He also desired to ask the author's opinion of the use of centrifugal force for separating the latex, as opinion on the subject seemed to be divided. If the latex were produced in such very large quantities as seemed probable, it seemed to him that an accelerated system of separation would have to be employed; and from his knowledge of the use of centrifugal apparatus on sugar estates, he thought that might be a useful method.

Mr. WALTER HANCOCK said that, having devoted sixty years of his life to the manufacture of india-rubber and gutta percha, he had been intensely interested in Mr. Wright's valuable paper, because it gave to manufacturers much information in a small compass. It might be in the recollection of some of the older members of the Society that forty years ago, when the question of india-rubber and gutta percha was under discussion, he (Mr. Hancock) expressed his surprise that, considering the price india-rubber and gutta percha fetched in the market, no one had taken the trouble to cultivate them. He further stated that leaving out of consideration the rare metals, silk and india-rubber were two of the most valuable articles imported into the country; they were articles which grew of themselves, which required little cultivation, and after five or seven years produced a very handsome return upon the outlay devoted to them. He had been particularly struck with the quality of the rubber now imported from Malaya. One of the advantages he held out, when the matter was under discussion forty years ago, was that if the industry were placed in the hands of business men with a manufacturing turn of mind, it would be possible to obtain in this country india-rubber or gutta percha free from the great defects of which the crude article then usually imported was so full. It was then full of chips of the trees and an unfair admixture of adulterations, which sometimes increased weight 10, 15, and 20 per cent., for which the manufacturer had to pay the full price of the pure material. The beautiful uniform quality of the finest rubber recently imported was a matter for much congratulation. A great quantity of African rubber first imported into this country sold at 4d., 5d. and 6d. a pound, but it was ruined in the collection and by exposure to light and heat, so that after a short time it perished in the way in which india rubber did, not by drying, as gutta-percha perished, but by becoming a slimy mass which melted away. Owing to the care which was now taken, more particularly in the manufacture of Malayan rubber, in keeping the latex in a liquid state, not allowing it to be exposed to air, light, or heat, and the way in which it was afterwards manufactured, an almost pure india-rubber was obtained which deservedly fetched a high price, not only because it was clean and pure, but, being free from adulterations, a rubber was obtained which was more likely to be durable, and which did not contain in itself the elements of decay. There appeared to be, he was sorry to say, too much of a rush for promoters to issue the prospectuses of companies for the supply of rubber. Some of the old-standing companies which had a business organisation were

able to carry on the manufacture profitably, sensibly, and advantageously; but in some cases the unfortunate shareholders would ultimately find they had lost all their money. The question of the production of synthetical rubber had been referred to; but for the last 61 years there had been many similar threats made. He had many times tried to manufacture an article that would be equal to india-rubber and gutta-percha, and apparently for a time with success, but with the test of time it vanished. It either became dry and friable and rotted, or it became sticky like birdlime, and was utterly useless. He had very little fear indeed, within his time at any rate, of manufacturers being frightened by the production of a synthetical rubber. Even if it could be made, the question was how far it would be durable. Both india-rubber and gutta-percha possessed most remarkable qualities, two of the most important being their resistance to water and their insulating properties. He was afraid that synthetical rubbers or gutta-perchas would, in the course of time, by drying and decaying or by becoming sticky be utterly useless and unfit to compare with natural india-rubber.

Dr. HENRY STEVENS, in referring to the question of the production of synthetical rubber, stated that although Tilden had prepared a substance resembling rubber from isoprene, his results had been called in question in recent years, and in particular Harries, in Germany, had shown that rubber probably possessed a constitution which made its formation from isoprene improbable. With regard to the question of the quality of plantation rubber, there was an opinion abroad that it did not possess the nerve of the Amazonian Para; but, in his opinion, that could only be satisfactorily settled by vulcanising tests being made with plantation rubbers on exactly the same lines as with wild rubbers. He had himself, in the course of the last few months, carried out vulcanisation experiments with plantation rubbers which had given very gratifying results.

Mr. WRIGHT, in reply, after thanking the members for the manner in which they had eulogised the paper, said that with regard to the series of cautions which had been given to him, he forgot to mention one in connection with the tapping operations as carried out at the present time on a few estates in the tropics. Several planters appeared to be proud of the fact that they were able to manufacture their rubber from shavings, *i.e.*, the bark which was peeled away every day, or whenever the tapping operation was performed, contained a certain amount of latex, which, on drying, could be extracted in the form of rubber. They were evidently anxious to show a very high return from the bark shavings; but it was possible so to tap the trees that the outer bark would dry, and possess not more than 1 per cent. of rubber. To extract 8, 10, and even more per cent. of rubber from bark shavings, as had been stated in some reports recently issued, was, he thought, really more a disgrace that an honour. On some estates, where too rapid tapping had been carried out, very fatal results were observable. He had made experiments in connection with the subject in Ceylon, and he knew in one or two cases that, although the original tappings might give latex possessing 40 to 50 per cent. of water, and up to 50 per cent. of caoutchouc, subsequent tappings of trees which had been too frequently irritated, gave a latex in abundance, but one which contained 90 per cent. of water, and only 10 per cent. of caoutchouc. That was a most important matter which ought to be brought before the planters. He did not believe at the present time, owing to the precautions which were being taken, that there was the slightest danger of any disease for a few years to come. Mr. Hamel Smith referred to the question of cacao and rubber. Personally, he was not very much in favour of castilloa and cacao, and the only reports issued by the botanic department of St. Lucia and Dominica showed that much better results had been obtained when *Hevea brasiliensis* had been used in conjunction with cocoa instead of Castilloa. He strongly recommended *Hevea brasiliensis*. Mr. Smith also mentioned that the cacao would sooner or later go. Cacoa was a rather peculiar plant, the root system of the tree being quite unlike that of most other plants cultivated. It was not as compact as the root system of tea, coffee, or the cocoanut palm. The roots were widely separated and allowed of the penetration of the roots of other plants, and the two products—rubber and cacao—could grow for a considerable length of time. He had in mind one cacao and rubber plantation which was, he believed, 20 years old; the *Hevea brasiliensis* varied from 7 to 11 years old, and both products were doing excellently to-day. Mr. Smith also raised a question on the subject separating the latex by centrifugal means. Weber, Biffin, and a few others had reported succeesful experiments in connection with the latex of Castilloa, stating that when the latex of that species was subjected to centrifugal force in an ordinary creaming machine it was possible, owing to the large size of the caoutchouc globules, to seperate them. He (Mr. Wright) thought he could do the same with Hevea; but on placing the ordinary latex of *Hevea brasiliensis* in a centrifugal machine, which was made to revolve at the rate of 11,000 feet per minute, there was no separation effected. The caoutchouc globules in *Hevea brasiliensis* were very small, and even if the density of the mother liquor was increased by the addition of solutions of sodium sulphate, it still seemed impossible to separate the globules of Hevea by mechanical means.

On the motion of the CHAIRMAN, a hearty vote of thanks was accorded to Mr. Wright for his instructive and interesting paper, and the meeting terminated.

THE MEAT SUPPLY OF PARIS.

Prior to 1810 the butchers of Paris slaughtered animals in the streets and public squares, but at that time municipal slaughter-houses—abattoirs—were established, where animals intended for human food are inspected, and the whole process of slaughtering and disposal of the meat and offal are kept under official surveillance. There are in Paris three principal abattoirs, the largest of which, "La Vilette," is in the northern quarter of the city; "Vaugirard," which was opened in 1898, and replaced the old slaughter-house of Grenelle; and "Villejuif," where horses are killed for food. Any butcher may slaughter animals at these abattoirs on payment of a tax of one shilling and eightpence per 220 pounds on the meat so prepared. Butchers of the more important class, and specially licensed, are permitted to sell the meat which they have thus provided directly to the smaller dealers who keep retail meat stores throughout the city. Inspectors are in constant attendance and any meat found infected with disease, or otherwise unfit for food, is saturated with petroleum and condemned. Living animals which are found to be contaminated are required to be sold for a nominal price to the "Knacker," and this regulation is so effective that of the 250,000 head of cattle slaughtered annually in Paris, an average of 30 only per month are condemned. The abattoirs are open to the public from 10 a.m. to 7 p.m., and the American Consul-General in Paris says that invalids are frequently sent there to drink the warm blood of the oxen, which is thought by some to have a curative effect. The slaughter-house of "La Vilette" is situated in the Rue de Flandres, in the extreme north-eastern district of the city, and is divided by the canal St. Martin from a large and well managed public market or stockyard, where cattle, sheep and swine are sold. The abattoir itself includes space for 2,950 cattle, 9,700 sheep, and 1,500 calves. The principal killing days are Tuesdays and Fridays, which precede the principal market days of Paris. The record shows that the average daily work during the autumn and winter months is to slaughter and prepare for market 1,200 cattle, 800 sheep, and 500 calves. The record of an average year is 250,000 cattle, 205,000 calves, 1,676,000 sheep and goats, was 126,000 tons of beef, veal and mutton, and and 230,000 hogs, and the product of the last year 16,000 tons of pork. The hides are sold at a special market, the Halles des Cuirs, which was lately destroyed by fire, and is to be rebuilt, and a considerable percentage of them is bought for export. "Vaugirard," the second in importance of Paris abattoirs, employs 50 butchers, and during an average year slaughters 30,000 head of cattle, 36,000 calves, and 200,000 sheep, which yielded 15,112 tons of meat. The third, and smallest, of the abattoirs, "Villejuif" provides meat for the board of public charities, and slaughtered during an average year 15,000 oxen, 9,000 calves, and 65,000 sheep. Both "Vaugirard" and "Villejuif" have departments for slaughtering horses, donkeys and mules and the total nnmber of such animals disposed during a recent year, was 18,000 horses, 250 donkeys, and 50 mules, which yielded 4,417 tons of meat. Butchers and meat dealers who sell horsemeat are required to have a special sign, a horse's head, over their places of business, and it may not be sold at a store not thus designated. The last year for which complete statistics concerning the meat supply of Paris have been published in 1903. From the reports of that year it appears that 267,027 cattle, 274,390 calves, and 2,047,770 sheep were slaughtered at the city abattoirs, and produced 327,616,000 pounds of meat, of which 259,796,000 pounds were consumed in Paris, and 71,044,000 pounds exported. Some of the choicest of French beef comes to England where the fillets and other prime cuts are in demand for clubs, hotels and the better-class restaurants. During the same year there were killed 282,508 pigs, which yielded 58,080,000 pounds of pork, and 29,370 horses, which furnished, 15,342,000 pounds of meat, all of which was consumed in Paris. A striking feature of all these statistics is the very large percentage of calves slaughtered, and veal consumed in Paris, in proportion to other meats. This is mainly a result of the careful thrift of the French peasant, who makes a point of generally having on his premises one or more calves, which are fed on skimmed milk combined with other food materials produced at home, so that the selling price of the fatted calf is, to a large extent, clear profit. The carefully enforced inspection system, which subjects every animal intended for slaughter to examination, prevents the killing of immature calves, and the veal of Paris and other French cities is uniformly of excellent quality. The average meat yield of oxen killed in Paris in 1903 was 697 pounds, sold wholesale to dealers at the "halles centrales" for an average price of sixpence per pound. Calves yielded 155 pounds per head, of veal, which was sold for about eightpence per pound. Sheep yielded an average of 46 pounds of mutton, which sold for between eightpence and ninepence per pound. Pigs, 172 pounds each of pork, the wholesale price of which was about sixpence per pound. As a rule the butcher's meat slaughtered and sold in France is nearly all of home production. The native races of cattle, namely the "Limousin" from the central departments, the "Normandy" from the north-west, and the "Nivernais" from the department of Nièvre, are unsurpassed as producers of beef of the highest quality. The whole imported stock for slaughtering purposes during 1904 was only 14,409 head, of which 11,030 came from Algeria, 2,869 from Italy, and 510 from all other countries. With sheep the case is quite different, Land and grass are too valuable, except in certain limited districts, to be given over to sheep grazing, so that the mutton supply is largely of foreign origin. The record of 1904 shows that there were imported 1,169,635 head of sheep, of which 1,078,225 came from Algeria, 30,000 from Tunis, 16,327 from Montenegro, 3,255 from Spain, 2,200 from England, and 19,300 from Russia. The pork supply is almost exclusively home grown, only 3,000 pigs having been imported into the whole of France

during the year, whereas 73,000 live pigs were exported to Switzerland. The intelligent, careful thrift of the French farmer, the rational system of inspection of animals and meat before, and after slaughtering, the cleanliness and orderly management enforced at the abattoirs and the "halles" where the meats are sold, combine to render the meat supply of Paris regular, abundant, and equal perhaps in quality to that of any city in the world.

THE UTILISATION OF EXHIBITIONS IN GERMANY.

A movement has been started in Germany for utilising national and international exhibitions in the promotion of foreign trade, and a permanent commission for exhibitions, which has just been established in that country, will occupy itself with matters pertaining to all large exhibitions, whether they be held in Germany or in foreign countries. It will be the purpose of the new organisation to obtain exact data as to the aims, extent, and possibilities of each exhibition planned. Fully informed, it will be in a position to give precise practical directions to inquirers, with the object of promoting German manufactures and trade. It has happened in the past that an exhibition has been projected abroad with some well-sounding name, and under plausible auspices, which has been largely speculative, of very limited compass, where medals and highest awards are supposed to have been granted for a pecuniary consideration. To protect exhibitors, however, against such eventualities will be one of the objects of the commission. The American Consul at Planen says that this organisation, primarily a patriotic one, will also endeavour to act as intermediary between the management of the various exhibitions and German exhibitors, so that the latter will not individually have to correspond, in more or less uncertainty, with the promoters of the exhibition. Greater solidarity will result in the representation of national interests, and where these are sparsely shown, or lacking, the results of a protective supervision are reckoned upon to call attention to an opportunity likely to be neglected. The commission has the support of the great manufacturing and commercial interests of the country, and will be in touch with the Government. Although many of the German exhibitions are only of local importance, it is not unlikely that certain British interests could be advantageously represented and developed. For instance, the agricultural fairs, such as those held annually at Düsseldorf, can be utilised for the display of farming machinery. In machinery and industrial exhibitions, which are held from time to time, there is a wide range for remunerative business. An exhibition for out-of-door sports affords a good opportunity for showing portable houses, tents, camping outfits, fishing-tackle, guns, &c. In the poultry shows, incubators, and various patent poultry-house appliances, have an excellent chance.

HOME INDUSTRIES.

Insurance Companies and Earthquakes.—The insurance world has taken to heart the lessons of the San Francisco earthquake, and is insisting upon conditions of insurance which will make a repetition of the San Francisco losses impossible. Policies will have clear and specific conditions exempting from liability for fires resulting from earthquakes. In San Francisco it was not so. All excepting two or three companies doing business there relied upon a condition which exempted them from liability for fires in fallen or partly fallen buildings. The common idea was that the first effect of an earthquake would be the fall of the buildings. That proved not to be necessarily the case. It is now better realised that electric light and telephone wires, gas pipes, and all the many applications of artificial light and heat to trade purposes—under the streets, overhead, and inside buildings—make the risk of fires resulting from earthquakes greater than was ever anticipated, while the almost certain simultaneous destruction of the water supply takes away the means of extinguishing them Insurance companies have, therefore, to protect themselves against these risks, and it is becoming evident that the only safety will be in the adoption of a condition which will make their non-liability absolutely indisputable. There is, of course, the other question of insurance companies giving insurance policies against fires resulting from earthquakes. Where that is done there will have to be a very substantial extra premium to cover the risk in San Francisco and other parts of the world where earthquakes are frequent, or comparatively so.

Home Railways and Stocks. — Attention has more than once been directed in these notes to the low price of home railway stocks. Since this was pointed out there has been some little improvement, and it is reasonable to assume that it will go further. For the depreciation in recent years has been very heavy, excessively so, as many think, having regard to merits. However that may be, the fall itself is indisputable, and is strikingly illustrated by tables compiled by the *Economist*. These tables give the current quotations of the ordinary stocks of all the principal railways, the dividends for the whole year 1906, and the yields based upon them. The years taken for comparison are 1897, 1902, and now. The fall in value is particularly noticeable in the case of preferred ordinary stocks bearing a fixed rate of dividend. The Great Northern 4 per cent. dropped from $122\frac{1}{2}$ in 1897, giving a yield of $3\frac{1}{4}$ per cent., to 99 in 1902, and 99 at the present time, at which last figure the yield is $4\frac{1}{16}$. The 6 per cent. stock of the same company was quoted $195\frac{1}{2}$, giving a yield of $3\frac{1}{16}$ in 1897, to $152\frac{1}{2}$ in 1902, and $149\frac{1}{2}$ now, the last price giving a yield of 4 per cent. South-Western 4 per cent. was at 134 in 1897, and is now 102, giving a respective yield of 3 and $3\frac{15}{16}$. Brighton 6 per cent. was at 200 ten years ago, and to-day is

quoted at 141, the respective yields being 3 and 4¼. The contrast is even more remarkable with regard to the ordinary and deferred stocks. The dividends distributed in 1906 were all at higher rates than those for 1901, yet prices are substantially lower at the present time. Take the premier stock, that of the London and North-Western. Last year's dividend was 6⅜ per cent. against 5½ per cent. for 1901, but the price is only 149½ against 162 in 1902, the yield being 3⅜ five years ago as against 4½ now. In 1902 the highest yield was $4\frac{1}{16}$ per cent. on London Tilbury stock and $4\frac{1}{8}$ per cent. on Great Northern Preferred. Now the highest yields are 5⅜ per cent. on North London stock and 5 per cent. on Brighton Deferredr Out of twenty-four stocks eighteen now give a return of 4 per cent. and upwards; five years ago only two stocks yielded as much as 4 per cent., and five gave a return under 3 per cent. It would seem from these figures, and others that might be submitted, that at present quotations first-class railway stocks are exceptionally cheap, for there is nothing in the general outline of an unusually disturbing character.

The Port of London.—At the time of the introduction of the London Docks Bill the hope was expressed that it might be possible to arrive at some general agreement which would enable the Government to support it, and so pave the way for the changes and improvements which are indispensable, and must be brought about without much further delay, if London is to retain its position as the greatest port in the world, a position it has held for the last 200 years. That hope has not been realised, but an exhaustive review of the position, contributed by a correspondent of *The Times*, demonstrates the pressing character of the problem to be solved. It is pointed out that the docks are now working at their maximum capacity, and there is no room anywhere for another line of large steamers. The Port of London has maintained its position not as the result of improvements in the river, or in the facilities afforded by the docks, but because the port is the centre of a large population with all its natural needs, and the financial and trading centre of the Empire. Moreover, London has many natural advantages. It is well situated for trade with all parts, its shipping is well sheltered, it has a good tidal river, and a good natural scour, and there is no bar. But the port is in danger of losing some of its trade, largely owing to the enormous increase in size of ocean going vessels. A great advantage of foreign competing ports is that with them public ownership and control are universal, Copenhagen and Marseilles alone excepted. The ports are controlled by national or local public authorities. In Germany, Bremen and Hamburg, they are administered by the States. At Rotterdam and Antwerp they are governed by the municipalities, while at Havre, as at all other French ports, the docks and quays are controlled and financed by a Central State Department with the assistance of the local Chambers of Commerce, and they are served by Government officials and workmen. With us for the last sixty years the river has been under the control of the Thames Conservancy, which two years ago obtained a Bill by which they were to provide a channel 1,000 feet wide, and 30 feet deep at low water from the Nore to Gravesend, a length of about 21 miles. Some progress has already been made with this scheme. But the depth of 30 feet is inadequate if it is hoped to draw to the Thames the largest vessels either mercantile or naval. Figures quoted by the correspondent referred to above demonstrate this. Seaward to the Nore there has always been sufficient depth, but the existing depth between the Nore and Gravesend is only about 25 feet to 26 feet, and in some places it is only 24 feet. Between Gravesend and the Royal Albert Docks, it varies from 24 feet to 16 feet and were in places only 15 feet. From the Royal Albert Docks to Millwall it is between 14 feet and 18 feet with patches only 12 feet. Between Millwall and the Thames Tunnel, there is a channel 300 feet wide and 16 feet to 13 feet deep. Over the Thames Tunnel the depth is only 13 feet, and between the Tunnel and London-bridge 14 feet at low water. Since 1902 there have been no dock extensions in London, it being impossible for the dock companies to raise the necessary capital until the Government intentions are disclosed. There is no dock either wet or dry on the river that can take anything approaching the largest liners or battle ships. What is wanted is this summarised by the correspondent already quoted. It conforms roughly to the recommendations of the Royal Commission—(1) A 35 feet channel up to Gravesend, a 30 feet channel from Gravesend up to the old London and India Docks at least, and the full width of the river wherever possible; (2) New wet docks, with a maximum width of entrance of 100 feet, a maximum depth of 40 feet, and capable of affording berthage to at least eight of the largest liners, with all necessary quay space, sheds, &c.; (3) Three dry docks, with maximum width of entrance 100 feet, a minimum depth over sill at low water of 40 feet, and 700 feet to 1,000 feet in length, all fully equipped; (4) The existing docks brought up to date, with plenty of quayage, and shed accommodation, and every appliancefor dealing with cargoes with the greatest possible despatch. This, of course, would mean a very large capital outlay, but something like it is indispensable if the Port of London is to hold her own against her Continental rivals.

The Cotton Industry. — The outlook for this industry continues favourable, except in one quarter. Relations between employers and employed are becoming strained. The cotton weaving employers of Lancashire have refused the application of the operatives for a rise in wages to the extent of 5 per cent. on the ground that the large majority of the manufacturing firms use bought yarn, and that this trade is in a very poor condition owing

chiefly to the high prices ruling for twist and weft. It remains to be seen what the operatives' officials will advise. The report is that they will be in favour of allowing the question to remain in abeyance, and that in the meantime the condition of the weaving trade be closely watched with a view to taking any further action later on that may be deemed advisable. Another statement is to the effect that the operatives will now consider the question of giving notice to cease work on a given date. About 120,000 operatives are affected, and a 5 per cent. advance would mean an addition of from 1s. to 1s. 6d. to the weekly wages of individual weavers, so that the rise would cost the employers from £6,000 to £7,000 per week. The fine counts wages question has been referred by the Oldham Employers' Association to the Central Federation in Manchester, so that the matter may be dealt with by the trade, as a whole. The operative spinners are asking for a general advance of 5 per cent. on the old standard list. The proposed conciliation scheme for adjusting wages according to the state of trade is not likely to be put into operation this summer. It may be hoped that the present flourishing state of the cotton industry will not be jeopardised by the refusal, whether of employers or workmen, to consent to compromise representing an equitable adjustment of opposing interests.

The Imperial Maritime Conference.—There will be no difference of opinion as to the desirability of an Imperial Maritime Conference to reconcile differences caused by Colonial legislation. Such a Conference has been sitting for some time past. At present the law is in a very anomalous and unsatisfactory condition. British vessels sailing from the United States in full accord with British shipping laws find themselves, on reaching Australia, under another and contradictory set of laws, and if such vessels go on to New Zealand they come under yet another set of laws altogether. That uniformity of maritime legislation throughout the Empire is wanted is more obvious than how it is to be brought about, for Colonial statesmen are by no means in accord with British views on the subject. The home view is that if a shipowner sends his ship to any British possession he should know that his property is placed under no other obligations than those to which it has to submit in Home waters. But that is not the view of Australia and New Zealand. One resolution actually passed lays it down "That no person should be employed as an officer on board any British ship registered in Australia, or New Zealand, or England, in the coasting trade of these colonies who is not (*a*) a British subject, and (*b*) thoroughly conversant with the English language." That is a very wide reaching suggestion. Under it a New England skipper could not command a vessel trading in those waters because he is not a British subject, and, say, a French-Canadian, though a British subject, might not be allowed to command because he could not speak English. Some surprise has been expressed at Canada not being represented at the Conference. There may be good reasons but they are not easy to discover. Canada is interested in the maritime legislation of the Australasian Colonies, and before long her interest will be a much larger one. It is true that hitherto no difficulty has been caused by any shipping legislation of the Dominion.

GENERAL NOTES.

THE UNITED KINGDOM AND CANADIAN TRADE.—It is noticeable that the percentage of imports from Great Britain in 1906 increased, as compared with 1905, from 23·98 to 24·42, whereas the percentage from the United States receded from 60·58 to 59·59. In the case of Great Britain, the percentage on dutiable goods increased from 29·88 to 30·40, receding in free imports from 15·14 to 15·03; the decline in American free imports being from 73·13 to 71·90, and in dutiable from 52·21 to 51·74. But if the total imports from the two countries are taken, it will be found that whereas the figures for Great Britain show a rise from 60,342,704 dols. to 69,183,915 dols., only those for the United States increased from 152,431,626 dols. to 168,798,376 dols.; or nearly double those of the United Kingdom. On the other hand, the percentage of exports to Great Britain rose from 50·61 to 53·96, as against a fall in the exports to the United States from 37·51 to 35·68. And so absolutely whilst the exports to Great Britain rose from 101,958,771 dols. to 133,092,571 dols., those to the United States only increased from 75,563,015 dols. to 88,001,309 dols. Canada's trade with the West Indies was slightly less than in 1905, when there was unprecedented expansion, but it may be noted that imports from Newfoundland increased from 1,059,417 dols., exports thereto showing a slight falling off from 3,473,713 dols. to 3,213,856 dols.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday Evenings, at 8 o'clock:—

MAY 1.—"The Defence of the Sea Coast from Erosion." By ALFRED EDWARD CAREY, M.Inst. C.E.

MAY 8.—"The Production of Coke and its Application in Domestic Fires." By PAUL SCHLICHT. CORBET WOODALL will preside.

MAY 15.—"Trypanosomiasis or Sleeping Sickness." By HERBERT W. G. MACLEOD, M.D., B.Sc.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

MAY 2.—"The Applicability to India of Italian Methods of Utilizing Silt." By SIR EDWARD CHARLES BUCK, K.C.S.I., LL.D., late Secretary to the Government of India, Revenue and Agricul-

tural Department. SIR CHARLES A. ELLIOTT, K.C.S.I., LL.D., will preside.

MAY 30.—"Irrigation Colonies in India." By LAURENCE ROBERTSON, I.C.S., Under Secretary to the Government of India, Revenue Department. CHARLES EDWARD HENRY HOBHOUSE, M.P., Under Secretary of State for India, will preside.

APPLIED ART SECTION.

Tuesday evenings, at 8 o'clock :—

APRIL 30.—"Lustre Pottery." By WILLIAM BURTON. J. C. WEDGWOOD, M.P., will preside.

∴ A collection of examples of lustre pottery from the Victoria and Albert Museum, and from private owners, will be arranged to illustrate Mr. Burton's paper, and will be on view during the afternoon and evening of the day of the meeting.

MAY 28.—"Sheffield Plate and Electro-plate." By SHERARD COWPER-COLES.

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

PROF. HERBERT JACKSON, F.I.C., F.C.S., "Detergents and Bleaching Agents used in Laundry Work." Three Lectures.

LECTURE III.—APRIL 29.—The problem of washing—Textile fabrics: easy methods of distinguishing between them chemically and by the microscope—Shrinkage of woollen goods—Behaviour of various fabrics with detergents and bleaching agents—Influence of acids, alkalies, &c., on the individual fibres—Precautions to be observed.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, APRIL 29...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Prof. Herbert Jackson, "Detergents and Bleaching Agents used in Laundry Work." (Lecture III.)

Farmers' Club, Whitehall Rooms, Hotel Metropole, S.W., 4 p.m. Mr. G. F. Slades, "What is required in a New Valuation Bill with regard to Methods of Assessment and Collection."

Geographical, University of London, Burlington-gardens, W., 8½ p.m. Dr. Fridtjof Nansen, "Polar Problems."

Actuaries, Staples-inn-hall, Holborn, E.C., 5 p.m.

TUESDAY, APRIL 30...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Applied Art Section.) Mr. William Burton, "Lustre Pottery."

Asiatic, 22, Albemarle-street, W., 4½ p.m. Major P. R. Gurdon, "The Khasis and the Austric Theory."

"Hellenic Studies," in the Rooms of the Society of Antiquaries, Burlington House, W., 5 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Prof. W. Stirling, "Stimulation, Luminous and Chemical." (Lecture II.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Annual Meeting.

Photographic, 66, Russell-square, W.C., 8 p.m. Mr. H. O. Klein, "With a Hand Camera to the Niagara Falls."

Anthropological, 3, Hanover-square, W., 8½ p.m.

Horticultural, Vincent-square, Westminster, S.W. 3 p.m. Mr. H. M. Veitch, "The Amateur and Horticultural Law."

WEDNESDAY, MAY 1...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Alfred Edward Carey, "The Defence of the Sea Coast from Erosion."

Geological, Burlington-house, W., 8 p.m.

African, Criterion Restaurant, Piccadilly, W., 8 p.m.

Royal Archæological Institution, 20, Hanover-square, W., 4½ p.m.

British Archæological Association, 32, Sackville-street, W., 4½ p.m. Annual Meeting.

Obstetrical, 20, Hanover-square, W., 8 p.m.

Royal Institution, Albemarle-street, W. Annual Meeting.

THURSDAY, MAY 2...SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Indian Section.) Sir Edward Charles Buck, "The Applicability to India of Italian Methods of Utilizing Silt."

Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Prof. E. B. Poulton, "The Fauna and Elora of Abyssinia Compared with those of West Africa." 2. Mr. Cyril Crossland, "Report on the Marine Biology of the Sudanese Red Sea" (communicated with an Introduction by the President). 3. "Formation of the Shone Cliff near Alexandria." 4. "Recent History of the Coral Reefs of the North-West Shores of the Red Sea." 5. Mr. E. R. Sykes, "Polyplacophora Collected by Mr. Cyril Crossland." 6. Mr. C. J. With, "Chelonethi (Pseudoscorpions) from Asia and Australia." 7. Mr A. B. Darbiseire, "Note on the Function of the Spiracle in certain Elasmobranchs." Exhibition:—1. Prof. E. B. Bulton, "Probate of the Will of Richard Anthony Salisbury" and "Manuscripts of Dr. W. J. Burchell."

Chemical, Burlington-house, W., 8½ p.m. 1. Sir W. Ramsay, "The Chemical Action of Exradio." Part I. "Action on Distilled Water." Part II. "Action on Copper Salts in Solution." Preliminary note. 2. Messrs. A. Findlay and E. M. Hickmans, "Freezing-point Curves of the Menthyl Mandelates." 3. Messrs. F. B. Power and F. Tutin, "The Constitution of Homoeriodictyol. A Crystalline Substance from Eriodictyon Leaves." 4. Mr. G. Le Bas, "The Relation between Valency and Heats of Combustion." Preliminary note.

Royal Institution, Albemarle-street, W., 3 p.m. Dr. A. W. Verrall, "The Bacchantes of Euripides."

Electrical Engineers (at the HOUSE OF THE SOCIETY OF ARTS), John-street, Adelphi, W.C., 8 p.m. Mr. C. Wade, "The Use of Wooden Poles for Overhead Power Transmission."

FRIDAY, MAY 3...Royal Institution, Albemarle-street, W., 9 p.m. Sir James Crichton Browne, "Dexterity and the Bend Sinister."

North-East Coast Institute of Engineers and Shipbuilders, Westgate-road, Newcastle-on-Tyne, 7½ p.m. Mr. J. L. Twaddell, "Sectional Work in Ship Construction."

Geologists' Association, University College, W.C., 8 p.m. 1. Professor S. H. Reynolds, "The Igneous Rocks of the Bristol District." 2. Mr. T. F. Sibly, "The Carboniferous Limestone Sections of Burrington Combe and Cheddar." 3. Mr. A. Vaughan, "Recent Researches in the Lower Carboniferous Rocks."

Philological, University College, W.C., 8 p.m. Annual Meeting.

Quekett Microscopical Club, 20, Hanover-square, W., 8 p.m.

SATURDAY, MAY 4...Royal Institution, Albemarle-street, W., 3 p.m. Prof. W. C. McIntosh, "Scientific Work in the Sea Fisheries." (Lecture I.)

Journal of the Society of Arts.

No. 2,841. VOL. LV.

FRIDAY, MAY 3, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, MAY 8, 8 p.m. (Ordinary Meeting.) PAUL SCHLICHT, "The Production of Coke and its application to Domestic Fires."

Further details of the Society's meetings will be found at the end of this number.

CANTOR LECTURES.

PROF. HERBERT JACKSON, F.I.C., F.C.S., delivered the third and last lecture of his course on "Detergents and Bleaching Agents used in Laundry Work," on Monday evening, 29th April.

The CHAIRMAN (Prof. J. M. Thomson, LL.D., F.R.S.) moved a hearty vote of thanks to the lecturer for his valuable and interesting course.

The lectures will be published in the *Journal* during the summer recess.

APPLIED ART SECTION.

TUESDAY, APRIL 30th, 8 p.m.; J. C. WEDGWOOD, M.P., in the chair. The paper read was "Lustre Ware," by WILLIAM BURTON, F.C.S.

The paper and report of the discussion will be published in a future number of the *Journal.*

⁎ A select collection of fine examples of ancient and modern lustre ware were exhibited in illustration of the subject of the paper.

Specimens were lent by the Board of Education (from the Victoria and Albert Museum), Mr. Lewis F. Day, Messrs. Thomas Goode and Co., Messrs. Liberty and Co., Messrs. Morris and Co., and Mr. W. Burton (from his own collection). The following manufacturers also lent examples of the productions of their kilns: — Messrs. Carter and Co., Messrs. Craven, Dunnell and Co., Messrs. Maw and Co., Bernard Moore, Pilkington's Tile and Pottery Co., and Mr. A. Wenger.

INDIAN SECTION.

THURSDAY AFTERNOON, MAY 2, 4.30 p.m.; SIR CHARLES A. ELLIOTT, K.C.S.I., LL.D., in the chair. The paper read was, "The Applicability to India of Italian Methods of Utilizing Silt," by SIR EDWARD CHARLES BUCK, K.C.S.I., LL.D.

The paper and report of the discussion will be published in a future number of the *Journal.*

PROCEEDINGS OF THE SOCIETY.

NINETEENTH ORDINARY MEETING.

Wednesday, May 1, 1907; MAJOR MONCREIFF PAUL, R.E., in the chair.

The following candidates were proposed for election as members of the Society:—

Coelho, Sertorio, M.A., Rua do Conselheiro No. 7, Nova Goa, Portuguese India.
Ford, James Francis, 17, Pembridge-square, W.
Gossain, Hem Chandra, Tezpur, Assam, India.
May, Theodore Martin, Assoc.Am.Soc.C.E., Rooms 1745-1749, 42, Broadway, New York City, U.S.A.

The following candidates were balloted for and duly elected members of the Society:—

Foucar, Alexandre Ferdinand Emile, Beaulieu, St. John's-park, Blackheath.

Felberman, Louis, Bladen-lodge, Bolton-gardens South, S.W.

Shaw, Mrs. G. Bernard, 10, Adelphi-terrace, W.C.

The paper read was—

THE PROTECTION OF SEA SHORES FROM EROSION.

By Alfred Edward Carey, M.Inst.C.E.

(Fellow of the Royal Geographical, Geological, and Chemical Societies).

I have been asked to speak to you this evening on the question of the Protection of Sea Shores from Erosion. This subject is one which may be regarded from a great many different standpoints, and it is moreover of considerable complexity. I cannot hope in an hour's paper to do more than allude to a few of the more salient features of the question, and my endeavour will be to lay before you practical rather than theoretical issues. Can the forces at work on a storm-beaten foreshore be controlled? If so, what are the readiest and most effective weapons for securing this object? What legislative changes are necessary in order to secure this result? In a satisfactory answer to these questions lies the solution of the problem. When Queen Elizabeth was "crediblie enformed that the Queene's Majestie's towne of Dunwytche . . . . . was by rage and surgies of the sea, daylie wasted and devoured; and the haven of her highnes said towne by diverse rages of wyndes continually landed and barred, so as no shippes or boates could either enter in or oughte, to the utter decay of the said towne," her remedy was simple. She ordered the bells, lead, iron, glass, and stone of Ingate Church, and the lead from the chancel of Kessingland Church to be sold and the proceeds lent to the town of Dunwich.

The same havoc is going on now on large areas, more especially of the Eastern coast of England, as in Queen Elizabeth's day, and ways and means for combatting the evil are still a vital question of the hour.

So far as the legal aspect of the matter is concerned, there seems to be no shadow of doubt that the obligation of defending the coast-line of the United Kingdom rests upon the King's Government. Coke's dictum is—"The King ought of right to save and defend his realm, as well against the sea as against his enemies, that it should not be drowned or wasted."

A long series of Judges of the greatest eminence, whose decisions reach down to the present day, have held precisely the same view, and judicial opinion going back to the reign of King Henry VI. supports the same contention. The difficulty is that if the Crown—or rather the Public Department concerned—does not move in the matter, how is it to be compelled to do so? There is practically no remedy, the only expedient the *Subject* has being to proceed by petition of right.

Broadly speaking, the Woods and Forests Department have control between high and low water levels, and below low water mark the rights of the Board of Trade come in; but on a coast-line, the boundary of which is continually shifting, how can these lines be satisfactorily defined? Endless disputes have arisen in settling points arising from this issue.

Then, again, lords of the manor and others have, either by Royal grant or immemorial usage, acquired in many localities the right of the removal of shingle and sand. This power is frequently exercised in such a way as to menace the safety of a contiguous sea frontage. Each town or district council abutting on the sea coast has its own strip of foreshore to defend, and the works which it carries out, in all probability, by arresting the travel of the shingle and sand, are detrimental to the districts to leeward of the one they control.

The first thought of the authorities in every district naturally is to safeguard the stability of the foreshore of that district; thus interminable complications arise, and almost every frontager or municipality is openly or covertly at war with the interests of his neighbour, who depends for the existence of his foreshore upon the regular travel of that circulating medium of defence provided by nature.

Added to these considerations is the fact that every longshoreman considers himself an expert in coast defence. Every boatman considers himself aggrieved by the carrying out of works which interfere with the foreshore, and may thus add difficulty or danger to the exercise of his calling. Small town and district councils can seldom be induced to look ahead and provide the means of defence against the inevitable forces of attack. When they do so they are often denounced by the indignant ratepayer for extravagance. I heard a case the other day of a local Board which had spent money in building groynes, "and now," said a sapient

ratepayer, "look at them, Sir, they are covered with sand and shingle and completely buried, and our money is wasted."

The first matter of primary importance to consider in devising works of coast protection is the profile of conservancy of the sea bottom contiguous to the foreshore. If at low water are found wide stretches of sand with a gradient of one in thirty, or flatter than this, it may be assumed that the problem to be attacked is a much less severe one than if the engineer has to deal with a cliff-bound coast, having little sea marge, or with a coast-line carrying large shingle at a steep angle.

The scouring power of the waves on the east coast of Scotland, will be found utterly different to the corresponding forces on the opposite Dutch coast.

A study of the type of boats which frequent a coast, furnishes a good idea of the sort of seas to expect. The Dutch fishermen, with their shallow flat-bottomed boats, have to deal with a surfy sea, but a sea that would be powerless to move those huge boulders, often up to two tons in weight, which the Scotch fishermen are not unaccustomed to see cast up from deep water, and which they term "travellers." When these boulders are overgrown with masses of seaweed, their buoyancy is greatly increased.

Many incidents may be cited of the almost incredible effects of storm action on a coast-line of extreme exposure. At the harbour works at Peterhead, concrete apron blocks weighing 47 tons each, and placed in position at a depth of about 40 feet below low water, were rooted out of their bed in the work and drawn seawards for a considerable distance.

On the Bound Skerry, an island in the Shetland group, a single mass of rock weighing 5½ tons, at a level of 72 feet above extreme high water, was not only moved but actually quarried from its position by the force of water shot into the air from the base of the cliff; and another adjoining mass of 13½ tons was displaced and tilted.

The effect of these gales is also far-reaching in the movement of sand, as it has been demonstrated, off the Devonshire coast, that lobster pots at a depth of 30 fathoms (or 180 feet) have been filled with sand.

Another extreme example of wave force is illustrated by the slide thrown on the screen.

At Dover Harbour tiers of concrete blocks weighing 40 tons each, and stacked three deep one above the other, were shifted bodily by the force of the waves in the manner shown in the photograph, and were only prevented from moving across the breakwater and falling over its lee side by the line of tramway. This, as will be seen, was twisted out of line and shape by the creeping movement of the blocks.

FIG. 1.

SHIFTING OF CONCRETE BLOCKS ON SOUTH BREAKWATER, DOVER HARBOUR.

Against forces of such magnitude it might seem hopeless to contend. It has, however, fallen to my lot to have to construct in various localities, at home and abroad, breakwater works. To watch a work of this description, creeping seawards week by week, and "beating the storms to laughter," is ample compensation for the many anxieties with which a harbour engineer has to contend in the execution of his duty.

The lantern slide now to be presented shows the root of the breakwater at La Guaira, Venezuela, a port on the north coast of South America, and lying immediately on the edge of the hurricane track. I had charge of the construction of these works, and the conditions subsisting at this spot are of almost incredible violence. The seas are oceanic in type, and about 120 miles to the north of the port the ocean depth is the second greatest of any portion of the globe. The effect caught in the photograph shown on the slide is one of great interest, as it will be seen how the recoil of a sea, striking a solid obstruction such as this, is met by the oncoming wave, and the result is a cascade of water at a considerable distance away from the structure, the forces of attack and recoil being mutually destructive. (Fig. 2.) This work was eventually carried into a depth of 47 feet of water, at a cost of a million sterling.

The lantern slides now to be shown will illustrate better than a long description the action of seas in deep water as they attack solid piers or similar constructions. For the use of these slides I am indebted to the firm of Messrs. S. Pearson and Son, by whom the

FIG. 2.

RECOIL OF WAVES FROM BREAKWATER AT LA GUAIRA, VENEZUELA.

National Harbour Works at Dover are being carried out. They are taken on the Westward, or windward, side of the Admiralty Pier. To use the sailors' phrase, the rollers are just beginning "to smell the ground." (Fig. 3.)

Going back again to the more immediate subject of the evening, it is a matter of prime importance to note the geological nature of the coast-line.* Measures which would be successful if dealing with a chalk cliff or cliff of primary rock, would be disastrously inadequate if applied when the cliffs are of tertiary clay, or "platimore," or "blue slipper," as it is locally termed in the Thames estuary, or if applied at the foot of a sea slope of glacial drift.

Another good indication of what may be expected is the vegetation both of the line of cliffs and of the bed of the sea. If the laminaria and other long-growth seaweeds are present in profusion and perfection in close proximity to a coast-line, otherwise of severe exposure, it will indicate that this portion of the sea bed is protected from the lash of the sea, either by projecting reefs, or by some set of tidal current. In the same way, if a cliff line is clothed with marine vegetation down to the limit of the foreshore, that fact will generally be an indication of an absence of extreme disturbing conditions.

It does not do to depend too implicitly on this latter class of information. The ordinary level of surf marks and vegetation may be completely swamped by tides of abnormal height, and plants like the sea eryngo and the horned poppy on these occasions are submerged without injury. I have recently had to advise a corporation on the East coast on the sea protection of the town, and found that on January 7th, 1905, the tide rose actually 6 feet 3 inches, above normal high-water mark.

The level at which the lepas, or barnacle, is found, may thus be a misleading guide as to the extreme range of the tides. In localities like the Channel Islands and the North of Scotland, boulders will be found projected by the sea far above high-water level.

In this class of observations you will thus see that the greatest caution is necessary.

At a recent meeting of the British Association, a paper was read by Mr. Clement Reid, F.R.S., in which he dealt with considerable novelty with the question of coast erosion from the side of archæological research and of recent geological change. He sought to establish the proposition that, at the period of Neolithic man,

FIG. 3.

ACTION OF SEAS ON SOLID PIERS, ADMIRALTY PIER, DOVER.

the sea level around Great Britain was about 60 feet lower than it is at present. His statement was:—"I can only say that a close study of the buried land-surfaces found in the alluvium at various depths down to about 50 feet

* I am indebted to the Council of the Geological Society for the map exhibited.

below the sea level, shows that oak trees flourished on the lowest of these ancient soils. This proves that the sea then stood so far below its present level that no sea water could reach the roots of these trees."

Following up this argument he inferred that, at the Neolithic period, our coast frontage included a belt of low ground extending out approximately to what is now the 10-fathom line. He expressed the opinion that about 4,000 years ago a fairly rapid and intermittent subsidence of the land or rise of the sea took place round our shores. It is conceivable that a greater or less percentage of the world's capital of water might be, at various periods, locked up in the form of snow and ice at the poles, but, except on this hypothesis, I confess I cannot see any basis of physical possibility for the supposition that a rise in sea level could have taken place. That land surfaces have been subject to elevation and subsidence is of course a common-place.

Upon questions such as those raised by Mr. Clement Reid, considering the authority with which he speaks, it does not become a layman in geological matters to dogmatise; personally, however, it appears to me more probable that sporadic and local oscillations of coast line have been the order of the day rather than a wholesale change of level.

Mr. Clement Reid instances in support of his argument the submerged plain off Selsey Bill, but the irruption of the sea over this area is an event within the historic period, as its present name of "The Park" indicates. The lands lying submerged to the south of Selsey Bill were, within historic times, a portion of the demesne of the Bishopric of Chichester.

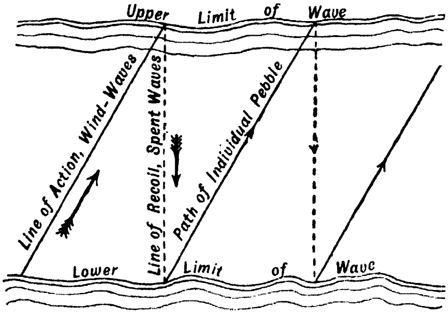
Mr. Reid further assumes that the above change in the relative levels of land and sea was completed about 3,500 years ago. At that date he states Stonehenge was being built. On astronomical grounds Sir Norman Lockyer, in his recent most interesting book on Stonehenge, gives 1700 B.C. as the approximate date of its building. Quite independently, on archæological grounds, Professor Gowland has fixed the date at 1800 B.C.

In the recent re-erection of the great fallen monolith at Stonehenge a number of stone tools were discovered, which had obviously been used by the workmen for dressing and socketting the masonry. These stone tools are unpolished, but Professor Gowland is of opinion that they are contemporary with the late Neolithic period. It would certainly appear that the evidence adduced on archæological grounds is slender.

Over large areas of the sea frontage of Great Britain, notably in the South Wales district, a change of approximately 60 feet in level has doubtless taken place within a comparatively recent and fairly defined period. Assuming that this change was widespread, it follows that, in advance of the present contour of sea and land, there must once have existed a coastal plain, and that a map of Great Britain of the period indicated would show an outer belt of low-lying land, intersected by deep-winding fjords. On geological grounds, Mr. Reid sees no reason why the present interlude of rest may not give place to further rapid oscillations of level.

Where seas are heavy and the foreshore is steep, the material of which the beach is composed is automatically graded. So well marked is this feature, that on the Chesil Bank for instance, a man thoroughly acquainted

FIG. 4.



TRAVEL OF PEBBLE.

with that singular ridge can in the dark, by picking up a few pebbles, approximately locate his position. The effect of the run of the sea on a beach is to produce a sieving action. As the waves impinge on a coast-line at varying angles they push the shingle backwards up the slope of the beach, and the recoil of dead water then drags a portion of the shingle down the sea slope by the path of least resistance, riddling out, under certain conditions, some of the larger stones. The normal line of travel of a particular pebble on the beach thus follows a saw-tooth path, alternately diagonal to and at right angles to the tidal lines. (Fig. 4.)

In a recent discussion Dr. Vaughan Cornish states the case thus: "If all the movements of sea-water, whether at the shore line or

elsewhere, are considered, it will be found that the principal part of the resultant movement is an unsymmetrical oscillation; that is to say, a long, slow movement occurs in one direction, and the water comes back to its former position by a shorter and quicker movement in the opposite direction. But though the two movements are equivalent, as far as the water is concerned, they are not so in regard to the transport of denser materials, which generally travel further in the direction of the shorter but quicker half of the oscillation." He then goes on to instance the Chesil Bank, and to show that the increasing coarseness of the shingle proceeding from Abbotsbury to Chesilton is due to the fact that this beach is sheltered to the east by Portland Bill, whereas from the West it is exposed to the waves, acting under the impulse of Westerly winds, thus driving all the shingle, big and little, towards Chesilton, whereas the waves produced by easterly winds have only sufficient velocity to drive the smaller shingle back towards Abbotsbury.

There is no department of engineering enterprise in which those in a responsible position receive more gratuitous advice than that of coast protection. Every longshoremen, as a matter of course, considers himself competent to offer an opinion, and often that opinion is well worth listening to. The only difficulty is, that boatmen and fishermen frequently have a rooted animosity to the construction of groynes, the reason at the back of their minds being the inconvenience and danger they are subjected to by concealed piling, in launching their craft, or on coming ashore. The fact of this animosity is apt to warp their judgment. At the same time they can often give much information which the charts or officials of a district may ignore. I am acquainted with a district on the coast of England, where, at an absurdly small annual cost, several miles of most difficult sea-frontage were maintained intact for years by the old coast warden, who had little except his mother wit and the evidence of his own eyes to guide him. Upon his death the foreshore in question was handed over to the tender mercies of an official of the new-light order. He carried out a series of measures on novel lines, with the result that the foreshore in question disappeared wholesale.

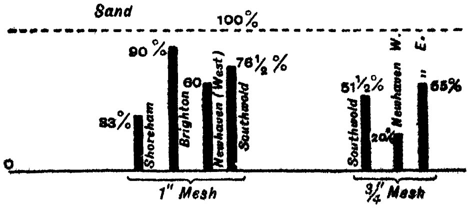
The movement of the column of drift on a foreshore is the resultant of the sum of all the forces that play upon it. Its contour may be moulded in a hundred different ways, but the dominant forces of wind and wind-waves define its ultimate shape.

On the East Anglian coast the most notable effect is that produced under the "swipe" of the N.N.W. winds,—to use the fishermen's phrase. A N.N.W. wind then drives the waves approximately parallel to the coast-line, and the scour they thus set up tends to rake out any defences at the foot of cliffs. On this coast a singular phenomenon may generally be noted, and that is a steep ridge of sand which varies in position from considerably above low-water line, to a distance of 500 or 600 feet outside this.

At Mundesley, near Cromer, this effect is well defined and visible. At low water a long channel of impounded water, about 3 feet deep, remains well above low-water line. This forms the hollow to a crest of sand seawards of it. These furrows are locally termed "lows." The effect, which varies in position and depth, is due to the off-scour of the sand produced by the wind-waves when dead on shore or nearly so. These drag the sand down the slope, heap it up to varying degrees, and form a sort of longitudinal bar. This bar affords considerable protection to the coast-line by cutting down the velocity of the waves, and wherever a gap, which is locally termed a "swash-way," occurs, there is a notable increase in their destructiveness.

It may be well to say a few words on the kinetic energy of the waves and their action under varying conditions. Sir John Coode has left it on record that on one occasion, on the Chesil Bank, a single gale scoured out 3,763,000 tons of shingle, and, after the gale was over, he took a series of cross sections of the eroded bank, which revealed the interesting fact that its shape was approximately that of an inverted parabola. On the same spot a laden sloop of 100 tons burden was, on one occasion, carried by a gale to a point 30 feet above ordinary high water.

FIG. 5.



SHINGLE.

At Skerryvore a pressure of 6,083 lbs., or about 2¾ tons per square foot, has been

registered by dynamometer. At Dunbar the observations have been as high as 3½ tons per square foot, and at Buckie, on the Banffshire coast, as high as 3 tons.

Where deep water abuts on an exposed sea marge, with an unbroken fetch, enabling wind-waves to acquire a high velocity, 2 to 2½ tons per square foot may be looked upon as not an extreme estimate of the force of impact of waves. This force, however, obviously varies with the angle at which it strikes. The flatter the beach and foreshore the greater is the skidding action on the waves striking it.

The mistake which is so often made in laying out measures for coast defence is founded on the idea that, because the sea has such tremendous power, therefore the method to arrest it is to erect a barrier, designed as a direct obstruction, with the object of neutralising the impact of the waves in the same way that a target does that of a bullet. For this purpose solid mass and weight have to be pitted against liquid mass and velocity.

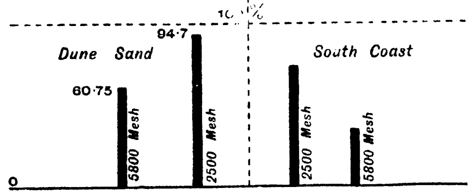
The mechanical effect of the blow of a heavy sea, striking a cliff or a sea-wall, is to hurl columns of water and spray upwards, and to set up a scouring action at the base of the obstruction.

The art of sea defence is to create and maintain upon a foreshore such a barrier of sea drift, either shingle or sand, as will absorb the velocity of the waves and bring them to comparative quiescence. Where shingle and sand form the barrier of arrest provided by Nature, measures have to be taken for maintaining them in a form best suited for that purpose. The construction of groynes is the usual expedient adopted.

Every river outlet or natural headland is in effect a groyne of greater or less extent. The guiding factor of a coast line, in relation to the travel of drift, is the wind dominant on that coast. Imagine a circular island surrounded by shingle, with wind action over a given period exactly uniform from every quarter. The components of the beach would, under these conditions, oscillate to and fro *ad infinitum*, marching, countermarching, and marking time, as the local forces acted upon them. At the end of the imaginary period I have indicated, their relative positions would be as they were at starting, except that their travel would have partly ground down the individual pebbles by attrition. As attrition proceeded, the circulating medium of defence of the island would change its angle of repose, thus varying the profile of conservancy. My suppositious case is pretty much on all fours with the littoral action on a well-groyned foreshore. There the natural travel, by reason of the dominant wind under the impulse of wind-waves, is arrested in detail, and oscillation, in the compartments between groynes, results.

The size of shingle on different foreshores varies very considerably. Large pebble boulders, as for instance those on Northam Ridge, may weigh up to 100 lbs. The size of ordinary shingle on the South coast is extremely variant. Thus, of the shingle of Shoreham harbour 33 per cent. will pass a 1 inch mesh; of that on the Brighton beach 90 per cent., and of that on the beach west of Newhaven 60 per cent. Taking a ¾ inch mesh, on the west side of Newhaven harbour 20 per cent. will pass, whereas on the east side of Newhaven 55 per cent. will pass this mesh. A pebble which will pass a 1½ inch mesh weighs about 1¼ ounces. On the east coast the shingle for the most part is practically small gravel. At Southwold, for instance, the percentage passing through a ¾ inch mesh is 51½ per cent.; 1 inch 76½ per cent., and 1½ inch 96 per cent. It is obvious that these variations will result in varying angles of repose.

Fig. 6.



SHINGLE.

The slope of a beach is modified, to an almost infinite degree, by the conditions of wind-wave and current from time to time prevailing. With a wind off-shore and normal conditions, it will be found that shingle on a beach will be heaped up, whereas with a wind on-shore the shingle on the beach will be dragged down. Where a slow ground swell strikes a coast line, with a sea of oily smoothness, a series of ridges or "fulls" are rapidly formed. The object of groynes is to divide a given foreshore up into a series of short bays and prevent the sea-drift being diffused over an extended area, so that its travel is reduced within compass of control.

From the foregoing remarks, I think the reason of the rule which is almost an established one on normal foreshores, *i.e.*, to

groyne at right angles to the coast-line, will be obvious. Of course special conditions of exposure and shelter may render it desirable to modify the angle of groyning, to attain a maximum of effectiveness. The prime consideration is to so arrange groynes that the contour of a foreshore shall be as little irregular as possible. A sea beach protected by a series of groynes resulting in big differences of level, on the windward and leeward sides, is evidence of bad design. It is obvious that wind-waves will heap the shingle on the windward side, and tend to scour the shingle away from the leeward side. By keeping the top of the planking of the groynes approximately at the height of the normal slope, this effect may be largely obviated. For this reason, in the majority of cases, concrete groynes are not desirable. With a timber groyne it is easy to take off or add to the planking, as the shingle alters its level, and it is thus possible to humour a beach and keep it tolerably constant in contour.

With a concrete structure the result is that, if it is built low, it is completely buried, and large quantities of shingle escape to leeward. At Hastings, for instance, a massive concrete groyne or pier is run out under the East Cliff, and the shingle heaped up against it to a level of about 22 feet above Ordnance datum. Immediately to the East of this again, there is a drop of some 20 feet on to the bare sandstone rock, which is being worn away by the scour of the sea. The cliffs beyond are not only bare of shingle, but themselves being severely attacked, so that landslips frequently occur. The tendency in all towns is to erect, what I may term, "long-stop groynes." The argument is: "This is the limit of our territory. Let us make sure at this point that we arrest every ton of shingle reaching us, and the folks beyond us must look after themselves." This is often a short-sighted policy. Taking Hastings as an instance, the Corporation have acquired the East Hills as a golf and recreation ground, and the authorities are considerably disturbed at the inroads taking place.

Wherever a line of coast exists the defence of which is a shingle barrier or a sandy flat, and in rear of which are marsh lands or a district easily flooded, it is necessary to construct a sea-wall or other fore-and-aft barrier, which will prevent in extreme gales the crest of the shingle being driven inland with a flat slope, and thus for all effective purposes being practically lost.

In no department of engineering practice is it more true than in that of coast defence, that the locality which hesitates is lost. In many instances had effective means been taken in good time, a frontage could have been saved at a fraction of the actual ultimate cost involved by tardiness in carrying out defence works.

This is one of the great factors in the present situation. I have brought the subject in this light before the notice of the Royal Commission on Coast Erosion now sitting. The difficulty of securing prompt and united action under present conditions, points to the urgent necessity of statutory reform. The measures which I have suggested I will detail later.

There are long stretches of the English coast-line in which the shingle and sand, forming the barrier of arrest, are backed by earth embankments.

I have personally to watch and advise measures of protection for over 60 miles of coast-line of this description. The great feature, in defences of this class, is to put the embankment well in rear of the foreshore. The shingle is thus forced back until its motion is arrested by the embankment. The shingle bank then becomes automatically moulded by the operations of Nature into the most effective contour for neutralising the momentum of the waves.

In situations of great exposure embankment walls would be futile. It is needless to say that, to be successful, there must be an abundance of the travelling medium of defence on which their efficiency depends.

The height to which a shingle barrier will be raised, under the conditions I have just indicated, varies considerably on different coasts. It varies as the tidal range varies, and also with the size of the component parts of the material in the slope.

The normal crest of a shingle bank, such as that between Newhaven and Seaford in Sussex, is about 20 feet above Ordnance datum (or mean sea level), the mean range of tide being 16 to 20 feet. Exceptional gales and tides will increase the height to which the beach is thrown, to a height of about 25 feet above Ordnance datum.

At the East end of the Chesil Bank the top of the shingle bank is 43 feet above high-water level.

On the East Anglian coast, where the coast-line is very steep-to, and the shingle is smaller in size, the range of tide in some localities being only 6 feet or 7 feet, the normal level of

the crest of shingle thrown up by the seas is only about 12 or 13 feet above Ordnance datum.

Turning now to a coast-line which depends for its protection on sand, the character and the fineness of this sand are important factors. Not only does sand consist of minute particles of flint, and other rocks ground to powder by the attrition of the travelling beaches, but it is often largely composed of broken shell. Its buoyancy in this case is obviously much greater. On the other hand, shell-sand if powdered very fine, will actually have a heavier specific gravity than quartz or felspar sand, the reason being that the interstitial cavities represent a much smaller proportion of the total volume in the one case than the other. Dune sand has a residue of about 5·3 per cent. on a 2,500 mesh sieve. On a 5,800 mesh sieve the residue is 39·25 per cent. Ordinary South Coast sand has a residue of 30·6 per cent. on a 2,500 mesh, and 72·75 per cent. on a 5,800 mesh. With coarse sand, fifty particles are about equal to one linear inch; of dune sand, about 100 to 150 particles are equal to one linear inch.

In still water the finest quartz sand drops to the bottom almost instantly, but a three or four knot current will disturb and oscillate normal sea sand. This is obvious on every sandy sea coast, where the line of sand-bearing water is visible under the tidal movement. The general slope of sandy beaches is about 1 in 30 above low water, and below this about 1 in 50, gradually flattening to about 1 in 100.

It was on a walk from Nether Stowey to Dulverton, in the autumn of 1797, that Coleridge, Wordsworth, and Dora Wordsworth evolved the lines—

> "And thou art long and lank and brown,
> As is the ribbed sea sand."

The haunted figure of the Ancient Mariner stands revealed in this image of a lonely and desolate sea marge.

The peculiar chequered appearance of sandy flats is familiar to everyone, but when one begins to think why sand should assume this particular contour, it is at first not easy to see any adequate reason. Wind action is, of course, the compelling force. This can be simulated by means of an artificial sand blast, and in miniature a ribbed sea sand can thus be moulded. The action of the blast affords a key to the problem.

Examining the effect of such an experiment, it will be found that the first essential to produce sand rippling is the absence of uniformity in the sand itself.

Take a sample regular in size and specific gravity, and, vary the intensity of the blast as you may, no rippling will result. It is clear, therefore, that the phenomenon is due to an assortment or grading of the sand grains. They are lifted and built up in regular sequence, the smaller or lighter particles being winnowed out, and tossed upwards on to a foundation of larger or heavier grains. A casual examination shows that the windward and leeward sides of these toy dunes are dissimilar. The former are flat, lying at an angle of perhaps not exceeding four degrees to the horizon and convex in form; the latter steep, lying approximately at the angle of repose of the material, and concave. They are heaped up by reflex action. The wind flowing in lines parallel to the surface, when it passes the crest of the slope, sets up a return eddy and thus lifts the lighter particles to the top of the ridge. Thus the ridges grow in height. The shifting and variation of the wind produce infinite combinations in ripple pattern. When one ripple flows into another, a double series of valleys results. When two ripples unite, the thinning of the leeward ripple, at the point of junction, is due to the *cul de sac* thus formed.

Moving sand plays extraordinary freaks. The fuljes of Arabia have been compared to gigantic horse tracks. They are horseshoe-shaped pits in the desert, gouged out at the crown to great depths. Mr. W. S. Blunt estimated from his measurements one of these to be 280 feet deep at the point. From this they slope up to the level of the desert, in a long wedge, and a crest or lip, above desert level, is to leeward of the crown. Imagine a uniform wind blowing across a sandy plain, in which here and there amongst the sand-waves are strewn solid obstructions, such as heaps of boulders. Where these lie the wind will, under certain conditions and intensity, scoop out hollows. Excavation thus goes on progressively, so long as the wind conditions favour it. Just as deep pools are dug by the waves at the base of projecting rocks or crags, so does the wind carve out and deepen the fuljes in the desert. The bottom of these pits is a hard substratum or platform, by which the digging action is arrested. Having thus reached a limit of depth, sand movement may forge ahead, causing the fulje to travel onwards in the direction in which the wind is blowing. Now let the wind slacken or shift, driving light

powdery sand before it, and this will gradually smooth out and obliterate the ridges, leaving only isolated pits, with sand lips at their front. Thus apparently have these strange basins been formed.

Sand may be a useful slave, but it is an exacting tyrant. On the coast of England and Wales are many wide stretches of dunes, which form effective buffer tracts between sea and land. In Holland, on the West coast of Denmark, and the South-West and other coasts of France, these barriers, which "serve them in the office of a wall," are jealously guarded by State enactment. In England we do things in a more happy-go-lucky fashion, but the law of the question of coast defence of the United Kingdom from erosion by the sea is worse than no protection to frontagers, and will have to be overhauled and remodelled.

Not the least of the matters to be regulated will be the systematic planting and cultivation of sand ranges in the Dutch fashion. Marram (Gaelic "Murran") grass (*Ammophila arundinacea*) is the bond most favoured.

The science and art of planting land reclamation and sand slopes, as a measure of maintenance and defence, have not received anything like the attention their importance deserves. It has been rather the fashion to despise these simple measures. The plant population which springs up on the muddy shores of reclaimed land or on sandhills, even down to high water level, is of the most varied character, and cattle will not touch many of the grasses most useful in binding sand slopes. Sea lyme-grass (*Elymus arenarius*), though rich in sugar, is one of the grasses cattle avoid.

It is hardly necessary to refer to shrubs like the Tamarisk (*Tamarix gallica*) and sea buck-thorn, the planting of which is so common a feature in watering-places.

Amongst the plants which thrive specially on muddy shores and salt marshes may be mentioned the black salt-wort (*Glaux maritima*), the various species of Atriplex or sea purslane, also the sea carex or sedge, and various species of sea thrift or *Statice.*

Of plants which thrive better on sandy sites may be named the yellow-horned poppy (*Glaucium luteum*), the sea holly (*Eryngium maritimum*), the prickly salt-wort (*Salsola Kali*), the various species of sand-wort, the sea pearl-wort (*Sagina maritima*), sea barley, sea wheat-grass, and sea cat's tail.

A very large number of grasses thrive on the fringe of high-water mark, and these nearly all possess long fibrous roots which penetrate enormous distances through the sand to reach a moist soil. The effect of this characteristic is that they mat together and anchor the slippery sand slopes, thus preventing them from being disturbed by wind action or beaten down by heavy rains. A cliff slope thoroughly overgrown with sea bindweed (*Convolvulus soldanella*) is almost impervious to this kind of action.

A systematic study of the whole problem, the careful cultivation of the grasses most valuable for the various purposes required, and the machinery for systematic planting will be matters of first-rate importance, when an organised campaign is instituted against the evils of coast erosion.

Quite recently evidence of much value has been given before the Royal Commission by Lord Montagu of Beaulieu, who described the accidental sowing, on certain mud banks in Southampton water, with the South American Nei grass, the result of which has been the reclamation of large areas of swampy ground upon his lordship's property.

Dun in Gaelic and Anglo-Saxon, meant merely a hill, but, so large a part did the sand barriers of the coast play, that the word has been monopolised to them alone. Its original meaning lingers in many a place-name. In the Lowestoft district it has become "the Denes." The Danish invaders called the sand ramparts "meols" or "meals," and this is still their regular designation in Northumberland and Lancashire.

Under steady wind action these dunes, or meols, sometimes slowly and irresistibly travel, burying towns and villages in their march. Similarly they have been known to oscillate back again, disinterring that which they had beforetime shrouded. The bonding power of the marram, or mat grass, is astonishing, and, so fully recognised was its value in fixing the dune slopes, that, in the reign of George II. a law was passed rendering it a penal offence to cut or injure the grass. Considering its usefulness for the purposes of thatching, and the making of mats and brushes, its protection by the enforcement of this law is most necessary.

In localities like the Persian Gulf and the N.E. kuckle of Brazil, blown sand is the dominant factor of the entire situation. The Persian Gulf is rapidly shoaling by reason of the vast quantities of sand travelling from the desert regions of Southern Persia. An almost perpetual condition of sand storm exists in certain localities. In the Arcachon district,

before protective measures were taken, there have been instances in which pedestrians have been smothered and buried by sand blizzards. A miniature desert plateau was beginning to form in that quarter of France. The French Government, however, took the matter vigorously in hand. About 200,000 acres were planted, principally with the *Pinus maritima*. The sea lyme-grass (*Elymus arenaria*) has also proved a useful ally. The entire district has been transformed by the measures taken. The travel landwards of the dunes has been arrested, valuable forests have been called into being, and the sand flats, instead of being a scourge and a nuisance, have become a health resort. Conversely, the pulling up of the marram grass on the Coubin estates, near Forres, in Scotland, in 1769, caused the devastation, in a single season, of an estate worth £300 per annum. Similar vandalism on the West coast of Jutland brought back a plague of sand there. Equilibrium in this and so many other cases goes hand in hand with the conservation of natural agencies. On the Dutch coast it is the practice to plant pines in rear of the sand dunes. These, when grown to maturity, arrest and precipitate the sand which otherwise would spread, like a cloud of locusts, inland of the coast line, carrying devastation far and wide.

The best object-lesson in the protection of sandy foreshores is that afforded by the work carried out on the Belgian, Dutch, and West Danish coasts. The groynes at Ostend are built of fascines, and run at right angles to the foreshore. The fascine work is 26 feet wide at the upper end, and 40 feet wide at the lower end. It is held down by stakes about 5 feet long, driven a few feet apart. Between the stakes blocks of stone are laid. On other parts of the Dutch coast, mattress-work, made of willows interlaced around piles, is employed, and upon these matttresses 18 inches of rubble basalt is laid. In many parts of the Dutch coast scupper nails are used to protect the timber work from the teredo. Generally speaking, one may say that the Dutch methods depend for their efficiency on the use of clay, brushwood, and block of stone, held in position by piles, or fir poles, driven into the foreshore. Under normal conditions the life of these groynes is stated to be 20 years. In Schleswig and Holstein, however, long groynes are employed as a protection to the sea dykes. They have to be extended from 430 to 560 yards seawards, and on this coast cause a heaping of the sand at the top of the foreshore. These groynes are 2 or 3 feet high, and 4 feet wide, and are formed of earth with interlacing matting. The slope on the windward side is 4 to 1, on the lee side 3 to 1. It will be obvious that measures of defence such as these would be useless on a sea coast of severe exposure, where deep water came close in.

Having thus passed in review, in the briefest way, the general conditions of the problem of coast protection, I may perhaps give instances of recent practice on the English coast. The constructive works which a foreshore engineer has to devise are groynes and sea-walls, or other fore-and-aft defences, where the land in rear of the foreshore does not afford the support necessary to hold up the bank of shingle or other drift. One most important matter to consider is that of the drainage of the land contiguous to the sea front. It is perfectly clear that, with a foreshore such as that near Herne Bay, where Tertiary clays and gravels are combined in varying layers, a wet season will work havoc with the line of cliffs. The water accumulates and lodges in the natural basins formed by the clay, and, oozing through some fissure or vein of porous material, brings down great masses, especially after frost. Meantime, the fret of the waves at the foot of the cliffs tends to cut away the support for the cliff and accelerate land slides. No measures of coast protection will prevent such weathering from above.

Along the East Anglian coast, where landslides are disastrous in extent, a slip-shod way of draining lands abutting on the sea prevails, and materially assists the work of destruction. There is no inducement to a landowner to spend money on land which next year, or next month, may tumble into the sea.

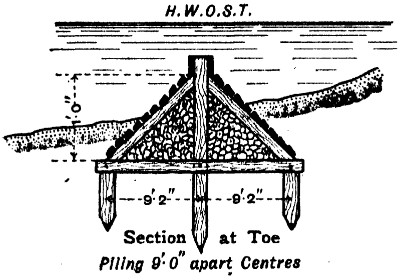
Some coast lines are peculiarly liable to be disintegrated by frost. Chalk cliffs, provided they are nearly vertical, will resist this action for a long period. Moisture falling upon chalk land gets away quickly, chalk being a most absorbent material. The worst that happens generally, if the cliffs are vertical or nearly so, is a slight weathering of the skin of the face of the cliffs. Where, however, chalk headlands stand at a moderate slope, they are more likely to give trouble, owing to the percolation of the water into the fissures in them.

The sandstones do not come off so well. Many of the loosely-knit sandstones are liable to be split by water penetrating into veins, freezing, and thus wedging off great masses. This question, however, is rather alien to the

immediate matter I am endeavouring to deal with, viz., coast defence.

At Bridlington, in Yorkshire, five "A" groynes, similar in section to Fig. 7, were built in 1868, and two of them still exist.

FIG. 7.



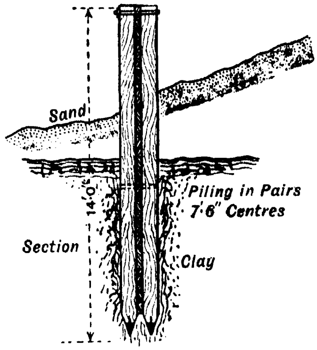
"A" GROYNE, BUILT AT BRIDLINGTON IN 1868.

At the top, or sea-wall end, the groynes were built 12 feet above the level of the foreshore, and at the bottom end 4 feet. The frames are 12 inch by 6 inch timbers, filled with block chalk and the sides are inclined to 35°. The piles are 12 inch by 12 inch, and the planking 9 inch by 4 inch. This type of groyne embodies almost every principle to be avoided. Being built to an arbitrary level above beach level, such groynes accumulate drift on the windward side and cause deep steps in the foreshore, which are unsightly, inconvenient and dangerous. Being built almost broadside to the sea, they set up scouring forces of the most formidable nature, forces not of conservation, but of destruction. Lastly, the cost of a groyne of this type is of necessity heavy. Groynes of a somewhat similar type have been constructed at Trusthorpe and Ingoldmells, on the Lincolnshire coast. In that case the transverse section of the groyne showed five rows of piles each 7 inch square, spaced 5 feet apart. The centre portion of the groyne rose about 3 feet above the sides, and the slope of the sides was 22½°. These latter groynes have retained the drifting sand, but on this part of the coast the sea is receding, and the problem is rather that of preventing inundation than of stopping erosion.

I remember an instance under which promenade works were built under these conditions. A contractor friend of mine, who attended the inaugural luncheon of the sea wall from which the sea was withdrawing, summarised the situation by saying that it appeared to be a case in which "the sea saw it and fled."

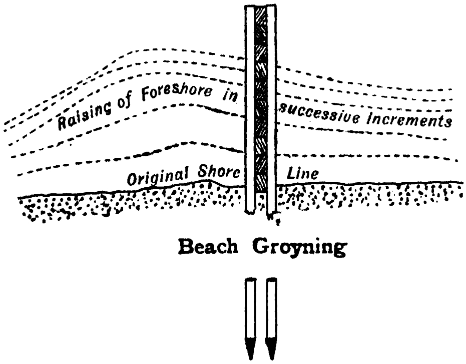
The type of groyne which, under normal conditions, I find most effective is that now to be shown. I have recently carried out the defences of a corporation in which the ravages of the sea were extreme, by building a series of groynes of this type. The piles are 10½ inch by 10½ inch, driven in pairs, 8 feet centre to centre, leaving a space for 4 inch planks, to be bolted between. Owing to extreme severity of the conditions, the piles had to be about

FIG. 8.



ADJUSTABLE GROYNE.

FIG. 9.



Beach Groyning

21 feet long. The planks bolted between the piles are arranged to break joint. By carefully watching the accumulation or depletion of moving shingle and sand, and by taking off or adding planks, as the state of the foreshore indicates the necessity for doing, an effective sea beach can, by groynes of this type, be coaxed into existence. A few tides' neglect may however undo the accumulation of weeks.

These groynes have cost about 28s. per lineal foot to construct.

On less exposed coasts in which the piles need only be say 14 feet long, the cost of similar groynes is about 18s. per lineal foot.

Taking 15 groynes to the mile and assuming each groyne to be 100 yards long the cost per mile for groynes, such as those at Hove and Hastings, which are massive and high, and have oak ties, would be about £10,000. Somewhat similar groynes but with struts instead of oak ties, such as may be seen on the Cromer coast, cost about £8,500 per mile.

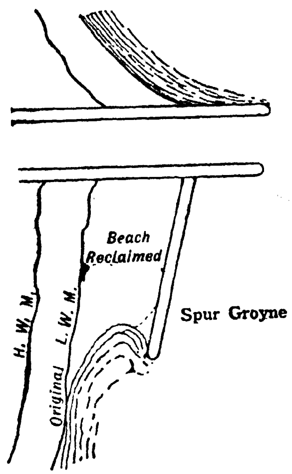
Low groynes of the single pile type like those at Felixstowe and Worthing, cost about £1,250 per mile, and similar groynes, but with double piling, vary from about £1,500 to £2,000 per mile, according to the length of piling necessary.

I may perhaps, in passing, mention that there have been several patent claims for groyning, notably that of the late Mr. E. Case, who was the engineer of the Romney sea defences, which are secured by the Dymchurch wall. His patent (1896) was, however, upset in the Court of Appeal. His method of constructing groynes was to fix uprights in pairs. They were of a light character, and held in position in the beach by being concreted into excavated pits. The planking was bolted between the pairs of uprights. In the coast protection works at Dymchurch Mr. Case was undoubtedly highly successful. He advocated building groynes from the lower part of the foreshore upwards, but did not carry the groynes so far as the top end of the sea-wall, or other fore-and-aft protection work. This latter arrangement often results in dangerous scour round the head of the groynes, and in my view is undoubtedly a mistake. On exposed frontages the Case system has been of doubtful utility, as the concrete bases, into which the uprights are bedded, are liable to be scoured out. In this case the entire groyne comes to grief.

The effect of successful groyning on a steep foreshore is that the slope of the shingle, forming the foreshore, is flattened, and, in order to produce a satisfactory contour, it is therefore obviously necessary that shoaling should take place beyond the original line of low water. It is, therefore, necessary that the groynes should be carried below low-water mark, and this extension (when deep water originally existed close inshore), is the measure of the efficiency of the groynage. To extend groynes below low water, it is either necessary to drive close sheet piling, or to take every opportunity as the beach increases, to add planking, and thus to push the structure seawards, by degrees.

The advantage of the expedient of spur groynes (*i.e.*, groynes running from a given structure parallel with the coast line) is one of which an instance may be seen immediately to the south of the entrance to Lowestoft Harbour. A spur groyne is local in its effect. Its object is to afford protection to a short length of frontage, generally to some extent at the expense of the frontage to leeward of it. Where, for instance, entrance piers run out into the sea, on the windward side of which the travelling shingle is arrested, scour on the leeward side is a natural consequence. By means of a spur groyne the root of a leeward pier may be protected, as behind it shingle, sooner or later, gets driven, and permanently lodges, being sheltered from scour by the spur groyne.

Fig. 10.



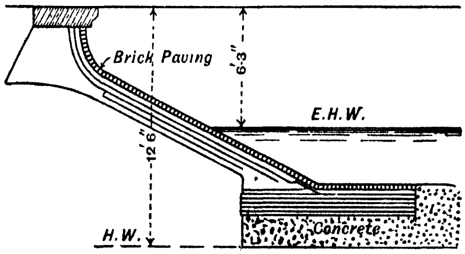
Turning now to the question of sea-walls, it is hardly needful to say that they vary in type within wide limits. As a rule, sea-walls are built fair on the face with a batter of 1 in 6 or 1 in 7. At Scarborough the sea face of the wall is curved to a radius of 17 feet, and the toe projects 15 feet beyond the bottom of the curve.

There are many other instances of sea-walls with curved fronts. I may mention that of Scheveningen, on a sandy coast. The apron of this wall is 20 feet long, it batters 1 in 4, and rests upon mattress work and clay 18 inches thick. (Fig. 11.)

Another common expedient, which has been adopted at Hastings and Blackpool, is that of having a projecting bull-nosing at the top of the wall. The idea of this design is that a column of water shot upwards under a wave stroke will be driven off at a tangent, away

from the Esplanade. So, to a large extent, it will, but the strain thrown on the wall is proportionately severe. Then there have been numerous designs for walls with stepped fronts, such as that for Bridlington and Margate. The Margate wall has a most elaborate contour consisting of a series of steps, each with rounded copes.

FIG. 11.



SCHEVENINGEN SEA WALL.

The idea embodied in the design of these various structures is that of breaking up the forces acting upon the wall, and making the details of these forces mutually destructive. The forces operating upon a sea-wall consist of horizontal direct blows of the waves; these, by deflection, set up vertical forces acting upwards, and similarly vertical forces acting downwards. The effect of the last is to excavate and tear out the root of the wall. The upward vertical force is one of the most fruitful sources of destruction, by reason of the cascade of water which thus passes over the sea-wall, and scours out the filling behind it. It thus sometimes digs a trench into which the wall is capsized inwards.

The conclusions which I personally have arrived at are that to build sea-walling, unless under conditions which will result in its being well-clothed with shingle or drift in front, is merely to court disaster. Such structures form admirable excavators. The weight of water rushing up the face of the work will on recoil set up dangerous scour at the root of the wall. Many such a structure has come to grief in this way. It cannot be too much emphasized that the object of a parade wall is that of forming a barrier for the travel of shingle inwards, rather than constituting a barrier for the wave stroke itself. Considered from this standpoint, it seems to me obvious that sea-walls of elaborate section involve a wasteful expenditure of money. The simplest and cheapest type appears to me the best. Such a structure is an ordinary wall of concrete, if necessary faced with granite, vertical on the front and stepped at the back. The best sea-walling, I may repeat, is a massed sea beach, and if sea-coast towns would be content not to push their building line so far forward, but to let nature build them a protection with the aid of a suitable system of groynes, they would, in nine cases out of ten, be in a far better position than they are when endeavouring to build sea-walls so as to encroach on the natural frontage of protection.

The latest practice in coast defence is that of dumping shingle artificially on a beach which has been depleted. The effect of this is often to restore efficiency and re-create a protective barrier. Some twenty years ago the sea-wall at Hove, immediately after construction, was seriously endangered by underscour. Twenty-seven thousand cubic yards of shingle were brought from Shoreham by barge and deposited as close inshore as possible, groynes were constructed, and the wall thus saved.

Similarly, between Newhaven and Seaford aoout 71,000 cubic yards of shingle were brought in railway waggons and tipped on to the beach between the groynes, and the result has been the successful protection of a length of low, exposed coast.

The question of coast erosion is one of urgency and of increasing urgency. The situation in many districts is so intolerable that some comprehensive national scheme must be evolved without delay. There are tracts of coast-line on which the invasion of the sea is a contingency continually present to the landowner and occupier. Slipshod agriculture is the natural consequence. The individual landowner may spend freely on defence works and find himself outflanked by the neglect—or more probably by the excess of zeal—of his neighbour. The principal areas of erosion are as follows:—

On the East Coast.—The Lias cliffs between Scarborough and Whitby, the coast line between Bridlington and Spurn Point (glacial drift), the East Anglian coast line from Cromer to Clacton (glacial drift), the Kentish coast from Herne Bay to Ramsgate (mostly tertiaries).

On the South Coast.—The Hastings sand cliffs near that town, the chalk cliffs between Newhaven and Brighton, points at the East and West ends of the Isle of Wight, the Oolite coast line between Swanage and Weymouth, the Lias cliffs near Lyme Regis.

On the West Coast—Points in Bridgwater

Bay, Somersteshire, in Cardigan Bay, on the North Wales coast near Colwyn, the Lancahire coast near Blackpool, and other localities.

A Royal Commision is now sitting to take evidence upon the entire matter and is investigating the subject with admirable thoroughness. I have, at the request of this body, furnished a memorandum of the legislative measures which the present situation seems to me to call for.

My proposal is for the creation of two Central Bodies to deal specifically with the problem, one taking charge of the entire coast of England and Wales, the other of the entire Irish coast. Such bodies should act with much greater economy and efficiency than now obtain. The present régime of local control is often wasteful and sometimes actually pernicious. I suggest that the Coast Commisioners should take over the powers and functions of the various bodies now controlling sections of the coast under Statute, and also the rights and powers of the Government Departments affected. The body of Commissioners in each case should not, I think, exceed five, as any large representative body would only perpetuate the evils of the present lack of system. The Commissioners I suggest should be appointed respectively by the President of the Board of Trade and the Chief Secretary for Ireland. The Coast Commissioners would nominate and appoint District Engineers or Coast Wardens, whose functions would be to advise Coast Commissioners as to the measures necessary for the maintenance of their respective coastal frontages, and the execution of such works as might be ordered by the Coast Commisions.

I further suggest that the coast line of Great Britain might be conveniently divided into the following districts :—

(1). Berwick-on-Tweed to the North shore of the Humber.

(2). The South shore of the Humber to the Essex shore of the Thames.

(3). The Kent shore of the Thames to Poole Harbour.

(4). Poole Harbour to the Severn.

(5). The Welsh coast.

(6). The Dee to the Scottish border.

The Irish coast might be divided into three or four sections.

The administrative functions of the new bodies would be the investigation of the titles, rights and obligations of the various authorities, landowners and others claiming jurisdiction or rights over lands contiguous to high water line and between high and low water levels. They would have authority to stop the removal of shingle or sand from a foreshore; and I have suggested that, should it not be proveable that such right had been exercised within 21 years, no compensation should be payable.

For the purposes of coastal defence my suggestion is that the Commissions should be the sole authority, with the proviso that their functions be restricted to works intended and designed primarily for the defence of lands and towns against sea erosion.

With regard to the thorny question of how the bill for the works carried out is to be met, my suggestion is that the salaries and expenses of the Coast Commissions and of their executive officers should be defrayed by an annual Treasury grant, and that the Treasury should further provide a capital sum to cover the plant necessary for the operations of the Commissions. This would be all that the Treasury would be called upon to find. The actual cost of works, carried out by order of the Coast Commissions, should I think be defrayed in respect of two-thirds by the County Council or Councils of the locality which includes the site or sites of the respective works, and one-third should be borne by the Corporations or local Councils whose frontages would be immediately affected. Public enquiries in every case would be held before any scheme of works was determined upon, and local views would thus be considered.

The main argument in favour of the suggestion which I have ventured to put forward is that a policy of prevision would take the place of the present lack of policy and of mere hand to mouth expenditure under panic.

The Coast Commissions would be able to utilise the surplus deposits of shingle and sand in one locality to make good the deficiency in another. It is on the maintenance of the circulating medium of defence provided by Nature, either thus or by natural travel, that the security of the entire coast line depends.

There are various precedents for the formation of bodies such as I suggest, and the broad conclusions which I have arrived at are the results of long experience.

In conclusion, I desire to express my thanks for the attention which you have been good enough to give to my imperfect development of a wide subject.

One often hears it said, "Sea Defence Works are generally expensive; coast land is often cheap. Let the cheap land go." It seems to me that from a national standpoint, such a creed is unworthy of the people, whose race-character springs from the mastery of the seas.

DISCUSSION.

The CHAIRMAN, in inviting discussion, said the author had given some very interesting information upon what was really a subject of national importance. Coast erosion unfortunately had a very serious effect, and it meant the loss of many acres of land to the sea, every year.

Lord MONTAGU OF BEAULIEU endorsed what the Chairman had said as to the ability of the paper. He had himself practical knowledge of sea defence work, and it had been a subject which had interested him very greatly for some years past. He therefore appreciated, perhaps to a fuller extent than some present, the arguments which the author had put forward. The author had referred in his paper to the evidence which he (the speaker) gave before the Royal Commission, with regard to a particular grass, called *Spartina altemiflora*, a grass which grew on the mudflats in the neighbourhood of Southampton Water. That grass had spread with amazing rapidity and persistence from the mudflats near Portsmouth to Hurst Castle, a distance of something like twenty-five miles. The grass, the origin of which was shrouded in mystery, was more like rice than anything else; in fact, in some cases it was more like immature oats. It grew in circular patches and spread. The remarkable point was that it would grow below high water mark, and on mudflats which were submerged twice a day by ordinary high water. He thought the author would agree with him when he said that he did not think there was another grass which would grow below high water mark. Of course, there were innumerable plants and reeds which would grow above high-water mark, and the author had mentioned one or two as arresting the progress of blown sand. Those were well known, but, as far as he personally knew, no other plant would grow below high-water mark in salt water or in estuaries. The grass helped to accumulate all kinds of detritus, and eventually raised the level of the mud above high water, therefore forming practically what was new land. He had had the history of the grass investigated, and only the previous day he had received a report on the grass from the Director of Kew Gardens. The report described it as being *Spartina altemiflora*, or *Spartina srpicta*, or, in some cases, *Spartina Townsendi*, there being three kinds. It was rather an interesting fact that all cattle liked it, it being sweet and full of sugar. It was, therefore, a useful grass for feeding cattle. Rabbits also were very fond of it. The report mentioned that the records of such grass extended over many years; but the first record he personally found of it was about the year 1833, when it was mentioned in some Hampshire records as having existed at what was then known as Itchen ferry, on what was now known as the Woolston shore of Southampton Water. It certainly did not exist on the mudflats in the Solent until within the last ten years. He could recollect when there was none in the Beaulieu River, which was a large estuary; but it was now entirely choked up with it, although the main water-way was as open as ever it was. He could not help thinking that the grass would be a most valuable addition to the means of reclaiming mud and sand flats near the mouths of rivers. He did not know how it would act in very exposed places; but he had noticed in the Solent when there was a considerable sea on, and where the grass grew down to the water's edge, that when big waves came in it seemed to withstand their action very much better than where the mud existed without grass. It might lead to the recovery to a great deal of land on the East Coast of England, in the mouths of the Thames and Medway, and along the Lincolnshire, Norfolk, and Suffolk coast. In his experience groynes must always be considered in relation to shingle travel. It was well known that a glacier instead of being motionless moved at a regulatar rate of progression; and shingle did the same. It might move very quickly in a year of great storms, and at a slower rate in years when there were fewer storms, but shingle on the shore was a continually moving body. If groynes were put up at right angles to the sea and not parallel to it, the first effect seen was that the groynes filled up gradually owing to the flow of shingle, until the shingle came to the top of the groyne; then it fell over like a waterfall, and filled up the next space, till the whole shore was covered. For over a hundred years past the foreshore on his estate in Hampshire had been defended in that way. The groynes had been constructed of ordinary fir or oak timber, 1 foot to 2 feet in diameter, driven down into the shingle for a couple of feet, and projecting in some cases as much as 6 feet on the leeward side of the groyne. The result had been that, when they were kept in order, erosion had been averted. He had recently had some photographs taken showing how, viewed from the westward, there were hardly any groynes to be seen, while from the eastward every groyne was visible, owing to the travel of the shingle in the English Channel taking place always from west to east. He thought the author would agree with him that, as a general rule, shingle always moved in the direction of the flood tide. It seemed to be a universal law that shingle moved in the English Channel from west to east, which might be attributable to the prevailing wind; on the east coast it moved from north to south, which also might be attributable to the prevailing wind; but he believed the flood tide had as much to do with it. The result was that if the flow of the shingle could be arrested, a perfectly sure sea defence was gradually formed. He agreed with the final sentence of the paper, that it was not worthy of England as a nation to say that, as the land was not worth much, they might let it go because the expense of preservation was greater than the land. He thought people from the overcrowded parts of the cities might be usefully employed in the reclamation of the lands round the sea coasts. On his estate he maintained 132 groynes,

which required renewing every 10 or 12 years. There was one agency in piling up shingle on shore the author had not mentioned, namely, the pod-weed. It began by growing on stones between high and low-water marks; in a short time, when it reached from 4 inches to 6 inches high, it developed at its ends tiny little bladders, which grew larger and larger. The gradual rise and fall of the water with the tide loosened the stones to which the weed was attached, as it was always pulling up. There came a time when the pod-weed was sufficiently powerful to float the stone up from the bottom; this might happen when there was an on-shore wind, in which case the stone was deposited on the shore at the utmost limit of the wave action. He had a very interesting collection of photographs, which he had had made for the Royal Commission, showing the various stages by which that was done. The question raised by the paper deserved national attention. The Royal Commission would, he hoped, do some good, but he felt there was a great absence of knowledge of how to defend the coasts against the inroads of the sea. If the author could get his paper circularised in a popular form, he thought there were many owners on the coast who would be only too delighted to know where they could get some practical sound advice on the question.

Professor Boyd Dawkins, F.R.S., remarked that for many years past he had studied coast erosion in various parts of the country, and had been filled with amazement to notice the extraordinary methods taken by engineers to meet the attacks which the sea was making on the coasts. In the next place, he had been surprised at the extraordinary apathy of those people who were most interested in maintaining this island at its present size or enlarging it. He fully accepted the principle laid down in the paper with regard to the correct construction of groynes. The present high, elaborate, and massive groynes formed an element of danger to the coast rather than one of defence. The principle of small groynes, raised to a few feet above the general level of the shingle or sand, was a principle which had been thoroughly proved to be the true one in all the cases which had come before him during the last thirty years. On the coast line between Brighton and Newhaven there was a series of large groynes with the shingle piled up on one side, and, owing to the waterfall action of the waves breaking over the groynes, they were being excavated on the lee side. The result was that, between Brighton and Newhaven, the coast was going by leaps and bounds, and areas which were formerly shingle and sand were now masses of bare chalk. Mr. Henry Willett, a friend of his, owned a small portion of land at Rottingdean, to the east of Brighton, and, being fully persuaded that low groynes were the correct thing as opposed to large groynes, he put in, for the defence of his own property, small groynes raised about two feet above the level of the sand and shingle, the result being that that was the only area which presented a bit of sand and shingle between Brighton and Newhaven. The coast-line between Folkestone and Dover was going by leaps and bounds, because the massive pier at Folkestone prevented the natural drift of the shingle, the coast being left open and naked to the dash of the sea. In his opinion it was more than the South-eastern engineers would be able to do to preserve that coast line for the sake of their railway. The development of the Admiralty Pier at Dover had blocked the drift of shingle in the direction of St. Margaret's, the result being those alarming land slips which were so rapidly diminishing the area of the land in that district. These were illustrations of the absolutely wrong action taken by engineers in attempting to arrest the drift of the shingle by large and massive barriers. As an illustration of the principle laid down by the author, a friend of his who bought a large estate to the south of the estuary of the Dee, being fully convinced that high groynes were a mistake, tried the experiment of having small movable groynes, consisting of small stacks driven down into the sand. Boards were also screwed on to the stacks about one foot above the normal level of the sand, and in some places rough hurdles were used. The result of that action had been that his friend had added 1,000 acres to his estate. In his opinion the principle which the author advocated ought to be adopted everywhere in this country. It was a mistake to make large massive masonry dams to break the force of the sea, because if a plus quantity was obtained on one side, a considerably greater minus quantity was obtained on the other. Another important point was the question of the carrying away of the shingle, which was the natural defence of the shore. How any reasonable body of people could be induced to allow shingle to be carried away from a shore line was more than he could ever understand. Nevertheless, it was going on almost everywhere; it ought to be stopped. In some cases the ignorance was so crass on the question of coast defence, that he had known cases where blocks on the foreshores had been actually broken up for the purpose of being used in the construction of a sea wall. The matter was one of enormous national importance; and it had been a very great pleasure to him to listen to a paper in which the ideas on which he and some of his friends had worked during the last twenty-five years, were brought before the public in in such an efficient way.

Mr. W. Whitaker, F.R.S., said it had often been forced on his mind, in the course of many walks along the coast, how difficult it often was for a public body to defend itself. For instance, the southern end of the town of Lowestoft was disappearing, although a great amount of money had been spent on it. The authorities might do what they could within their own border, but unless the work was carried beyond it lost half its value. Piecemeal work was of no use at all, and very often worse than useless. He had seen on the East Coast places where a land owner

had, at great expense, built up a sea-wall which he thought would protect his land, but it did not; the sea got behind it and brought it down. In his opinion there ought to be some central authority to look after the coast, much as the Local Government Board looked after other things; some system must be laid down on which the work could be done. It was extremely difficult in such matters to fight nature, because a little alteration might improve the land owner's particular piece of land, but one did not know what effect it might have a little way off. For that reason the work must be done systematically. There were parts where the land was practically of no value, but it must be remembered that to protect the valuable land it was often necessary to protect land which in itself was not valuable.

Mr. R. F. GRANTHAM said that, having had 30 years experience in the building of groynes and sea-walls on different parts of the coast, he agreed with Professor Dawkins, that low groynes were the correct form for preserving shingle on the shore. Groynes were not intended as wave-breakers, but to collect shingle or sand, which were the natural protection of the coast line His experience went further than that, because he found it perfectly possible to defend a long line of shore solely by means of groynes without any sea-wall, any form of breastwork, or timber work. He knew the Yorkshire coast well; and in his opinion the whole of that coast from Bridlington down to the Spurn could be very well defended by groynes, without sea-walls or breastwork. It was a question of time and great patience, but it could be done. He did not agree with the author where he said it was the rule that groynes should be run out at right angles. His experience was to give them a definite angle to the shore away from the prevalent wind. He had observed, from years of experience, that a more even distribution of the shingle on the two sides could be obtained in that way than by using a right-angle groyne. He had seen illustrations of that over and over again, where great accumulations were obtained on the shore on the windward side, and a great scour on the leeward side, which was due to a great extent to the groynes being placed at right angles to the shore. In the building of sea-walls he hada dopted a curved profile, which answered well; but if he were to build more he should be very much inclined, if he had money enough, to construct them on the section adopted at Margate, which was an admirable one, for the reason that, as the sea broke against the wall, the steps broke up the wave as it came up the wall, so that there was not the heavy recoil or splash over the top of the wall which there was when it was built, either with a slope or a curved face. He did not agree with the author's suggestion that a Commission should be appointed, and the country divided up into districts, for the reason that there were at least twenty-one Commissions of Sewers already in existence, which controlled large areas of the country, and it would be a difficult matter to sweep them away. They had under their control more than half a million acres of land, and had not only their sea frontages to take care of but the drainage in their districts, which depended on a number of sluices inserted in the sea-walls. He, therefore, thought it would be extremely difficult to take away the powers of those bodies, and put them into the hands of a general body. The great need was that some body should be established to control the shore, who would have the right of vetoing or amending any proposal which might be made for the building of a groyne or sea-wall.

The CHAIRMAN, in proposing a hearty vote of thanks to the author for his instructive and interesting paper, said that Mr. Carey had brought the very important subject of the prevention of coast erosion into review under three aspects, the Physical, the Engineering, and National. The National, though last, was not by any means the least; and it certainly behoved England as a nation to take the matter into account. Other nations were very much further ahead in that respect than England, just as, for instance, in the question of Forestry. Unless something was done, thousands of useful acres of land would go into the sea year by year. From the limited experience he had obtained in charge of the coast line under the War Department, he thought the whole question was summed up by the word "shingle." Once a coast was denuded of its shingle, and its treacherous boulder clay laid bare, one might say that they were thoroughly well in the mud, and there was no chance of getting out of it. The more modern expedient of dumping shingle seemed to be the only possible remedy under the circumstances. The general consensus of opinion was that the low groyne was the right thing; and, so, far as he knew, that was correct, provided the surface of the groyne conformed to the configuration of the foreshore, and, as the author had pointed out, the adding of further boards as the shingle accrued. There was no doubt there was very considerable difficulty in dealing with such an extensive coast as England possessed, and it was not to be supposed, as Mr. Grantham had pointed out, that the matter could be lightly undertaken without trespassing on somebody's rights. But something undoubtedly might be done, although he thought anything in the nature of complete Government control or State aid was very far off. The strict prohibition of the removal of shingle might very well be enacted, and also the putting into motion of some machinery whereby a neighbour was not allowed to carry out a system of groynes, according to his own peculiar ideas, which would cause considerable destruction to the land of his neighbour. In his own experience he had found that the evil could be reduced, to a certain extent, by tailing off the groynes as a neighbour's territory was approached, *i.e.*, not keeping up the same length and ending up abruptly, but tailing off, which prevented the sea making a dead set

against any particular part of the coast which was unprotected.

The vote of thanks was then put, and carried unanimously.

Mr. CAREY, in reply, said that Lord Montagu's remarks were extremely valuable, and, as far as he knew, entirely novel, the points he had raised being worthy of the most careful and exhaustive study, more especially the botanical side of the question. There was a very wide divergence of opinion as to whether the travel of shingle and the movement of the flood tide were necessarily connected and collateral, and the point had been fought a great many times; but it opened up too wide a subject for discussion on the present occasion. The remarks his lordship had made with regard to seaweed were also of a most important character. Professor Dawkins's remarks recalled to his mind several discussions he had years ago with his friend Mr. Henry Willett, and he entirely endorsed the very shrewd observations which that gentleman generally made in support of his argument. Reference had been made to the reckless way in which shingle was often removed from the shore. At Mundesley, on the Norfolk coast, there was a continual stream of carts day after day carrying shingle to the top of the cliff, where it was used for road metalling. He quite agreed with Mr. Grantham, that it was impossible to lay down a general rule that groynes should always be at right angles to the shore. Each individual case must be studied; but, broadly speaking, it seemed to him that general experience tended in that direction at any rate. With regard to the 21 bodies of Commissioners of Sewers which Mr. Grantham mentioned, he (Mr. Carey) acted for several of them; and therefore if the proposed Commission came into force Othello's occupation would be, to some extent, gone. At the same time, he thought it was the right thing that the matter should be taken in hand by some central authority. It seemed to him the negative powers which Mr. Grantham suggested would be extremely doubtful. All active interference would still be left to the local bodies, and in his opinion they never could or would work effectively.

Mr. H. J. BAKEWELL writes:—In accordance with the suggestion of the Chairman last night, I would like to state that my experience of groyne work, extending over twenty years, has shown that, so far as retention of shingle is concerned, both high and low groynes, properly planned, are, in most cases, equally effective. High groynes permit of being placed wider apart, but must be made proportionately strong, while the low groynes may be of lighter construction but nearer together. Where it can be arranged, the latter is to be preferred as forming a more uniform beach line. The cost may be considered in favour of the low groyne when carried out on a large scale. Terminal groynes, whether high or low, should be double, as the scour on the leeward side is greater and the strain intensified by the absence of further barrier to sustain the beach, and therefore a much stronger structure is necessary. The double groyne is, moreover, useful, inasmuch as it can be formed into a trap to regain shingle that may be swept back by change of wind and current. I may say that I have found this beneficial in my experience.

THE ARTIFICIAL SILK INDUSTRY IN FRANCE.

According to a recent report from Lyons several manufacturers in and around the city are employing artificial silk, or *soie de chardonnet*, as it is called, in the manufacture of light goods for summer wear, and it has been stated by one of the French companies engaged in this business that the exports to the United Kingdom, Belgium, and the United States, are holding their own, while the shipments to other countries show an increase. Artificial silk is being used in some factories in combination with the natural silk. In *mousseline de soie* the warp is made of natural silk, and the woof of chardonnet. In some houses a thread of chardonnet and a thread of natural silk are passed alternately on two different shuttles. The American Consul at Lyons says a great difficulty that the manufacturers of goods from artificial silk have to contend with is, that the stuff cannot stand exposure to dampness or the least rain. He is informed, however, that in bleaching the artificial with the natural article the difficulty is very largely overcome. It is also said that by combining a thread of chardonnet with a thread of natural silk the former adds a very desirable brilliancy to the finished material, which adds to its value as used in laces, passementerie, mousselines, ribbons, gauzes, and anything used in trimmings. A new article called "chifolineis," a species of goods manufactured from artificial silk, is used very largely in the trimmings of ladies' hats. All the milliners in France use it, and one firm in Lyons has orders for it for six months ahead. The artificial silk works at Besançon, which had dismissed many of their *employés* on account of a period of depresession, have recently been working on full time, and giving employment to nearly two thousand men. They export their goods to all the countries of Europe except Germany, where an arrangement has been entered into with a German company, by which the French company will not invade their market. The stock in the French company, which had fallen very low, has been marked by a steady rise. It is reported in Lyons that an effort to establish a mill in the United States for the manufacture of chardonnet silk has been adandoned on account of the high wages paid to American workmen. The manufacturers in Lyons say that it is more profitable to pay the 30 per cent. duty than to put up works there and pay the high wages to American workmen.

HOME INDUSTRIES.

The Tin Plate Trade.—This trade continues in a remarkably prosperous condition. At the close of 1906 there were 381 tin-plate mills, and 60 sheet mills working, and 22,000 people employed in them. At the present time there are 450 mills in operation. The Board of Trade returns show that the export of tinned plates for the three months ended March last amounted to 101,332 tons, as compared with 91,771 tons in the corresponding period of 1906, an increase of 10·4 per cent., with practically the same percentage of increase in value. The shipment of black plates for the same months exceeded those for the first three months of last year by 18 per cent., the increase in value being over 19 per cent. The output of tin plates in 1906 was the largest on record, with the one exception of 1891, when the American merchants were stocking their warehouses in expectation of the McKinley tariff. Last year the shipments of tin and terne plates (including black plates), amounted to 8,822,240 cwt., valued at over £5,500,000 sterling, an increase of 329,580 cwt. over those of 1905. This year the increase continues, and there is every prospect of the output of 1907 exceeding that of 1891. Each month this year has seen an increase in the number of tin plate and steel mills working. In spite of the high price of tin, and the consequent dearness of tin plates—last year's prices of tin plates ranged from 13s. to 15s. 3d. per box, f.o.b., the present quotation is 14s. 10½d.—orders continue plentiful, and assuming that tin remains under £200, the increased production of the first three months of the year is pretty certain to continue throughout it. Owing to the operation of the rebate of 99 per cent. Great Britain has been able to retain most of its tin-plate trade with the United States, but it is diminishing. In 1904 it was 71,862 tons, in 1905 63,050 tons, in 1906 only 61,518 tons. The trade with the Colonies remains practically stationary, with the exception of Canada, which took only 19,986 tons in 1906, as against 21,238 tons in 1905, the explanation being local competition and that of the United States. It may be noted that the quantities exported to these two countries in the first three months of 1907 show an increase of nearly 50 per cent. on that of last year, bnt it would be unwise to assume a continuance of this increase, and, indeed, Welsh manufacturers anticipate the eventual loss of the American and Canadian trade. Fortunately the market is widening in other countries. Europe is increasing her demand for the product. Owing to the devastation of the Baku and other South Russian oil centres by rioters last year, Russia took only 4,849 tons of tin plates in 1906, as against 31,272 in 1902, and of black plates 14,000, as against 31,000, but imports are now increasing again, the exports of tin plates to Russia for the past three months being 2,141 tons, as against 219 tons in the first quarter of 1906. With the exception of Russia, the exports to the leading European markets show substantial increase.

The Frozen Meat Trade.—The dependence of the United Kingdom upon foreign countries for its corn supplies is overwhelming. At the present time less than one loaf of every five consumed is made of home-grown wheat. But until now dependence upon the foreigner for meat supplies has not been in anything like the same proportion. This disparity is, however, diminishing. Ten years ago the imported beef, mutton, and lamb amounted to 32 per cent. of the consumption. To-day, if figures compiled by Messrs. Waddel and Co. are correct, as no doubt they are, of the total consumption in the United Kingdom frozen meats represent 17 per cent., chilled beef 9 per cent., imported cattle and sheep 11 per cent., so that 37 per cent. of the meat eaten in the United Kingdom is foreign. In 1903 the British consumer paid £10,123,592 for foreign beef, and £7,932,390 for foreign mutton; in 1906 the figures were £11,115,312 and £7,781,497; but, although the value of the frozen mutton consumed was somewhat less in 1906 than 1903, the quantity imported had increased from 4,065,776 cwt. to 4,137,132 cwt. And so with beef, the increase being from 4,805,813 cwt. in 1903 to 5,986,793 cwt. in 1906, The Argentine continues to be the chief source of supply. The exposure of Chicago methods prejudiced foreign meats, and for the moment checked consumption, but the effect was only temporary, and the popularity of Australian, New Zealand, and the River Plate meat was never greater than now. Next to the Argentine comes New Zealand as the source of our frozen meat supply. Australia was of course adversely affected by the great drought, but exports may be expected to largely increase now that the flocks and herds are once more rapidly growing. In the Argentine, the province of Buenos Ayres is suffering from drought, and meat exports will be affected this year. The meat trade of New Zealand with the United Kingdom shows uninterrupted growth. The home supply remains almost stationary, and but for colonial and foreign meats consumption must have been greatly restricted unless the public were prepared to pay much higher prices. It seems strange that the home supply does not increase, having regard not only to the steadily increasing population, but to the growing proportion of it which consumes meat in appreciable quantity.

Compulsory Arbitration.—The working of the Arbitration Courts in Australia and New Zealand has been watched with keen interest in this and other countries by those who desire better relations between capital and labour, and at first very favourable reports were received, but it would seem that the public directly concerned are beginning to regard them less hopefully. The Melbourne correspondent of the *Economist*, in a letter which appears in that journal of April 27, makes statements deserving of attention coming as they do from a very competent observer. He says the Arbitration Courts appear to be losing the power to command the allegiance of *employés*. In New Zealand the slaughtermen in several places struck for

higher wages than had been allowed them by the Arbitration Court. The Court fined a number of the men, but the strike was persisted in until the employers agreed to the demands of the men. The fines were then paid, but the fact remains that the award of the Arbitration Court had been ignored and a settlement made in defiance of it. Again, in Western Australia, in a dispute between saw mill owners and their workmen, the Arbitration Court adjudicated, but the men refuse to accept the terms, and in March were still on strike, "not against the employers but against the Arbitration award," to quote the general secretary of the Amalgamated Saw Millers' Union. Then there was the dispute between the colliery proprietors and miners north of Sydney. The Union decided not to have recourse to the Arbitration Court but to disregard its previous award, and after some weeks a settlement was arrived at between employers and employed. The powers of the New South Wales Arbitration Court have been much restricted by a judgment of the Supreme Court. In giving judgment the Chief Justice said, "The Arbitration Court was a Court of very limited jurisdiction. It was thought by the framer of the Act that this Act would give the Court a very extended and very extensive jurisdiction—that it would be an Act to set at rest all industrial disputes, and that strikes would cease. Unfortunately it was found by experience that the Arbitration Act had conferred upon the Arbitration Court a very limited jurisdiction indeed, and in place of putting an end to strikes the fact was that strikes were as prevalent as ever they were, if not more so, especially in certain industries. . . . . I am not surprised, to a certain extent, that the Court should struggle to have some jurisdiction. Its jurisdiction seems to be waning. Almost every case which comes before us is one in which we have to decide this question of jurisdiction. In some of these cases it would have been very well, possibly, if the Court had had the jurisdiction. In others it was very fortunate that it had not, because it was a distinct interference with the liberty of the subject." This does not look as if the principle of compulsory arbitration is making much headway. Much must depend upon the character of the *personnel* of the Judges who administer the law. The Judges can hardly be expected to display equal aptitude in measuring the importance and in assessing the value of trade conditions. They lack the knowledge only to be got from experience. "The best agreements made in Australia," says the correspondent already quoted, "are those that have resulted from Conferences between employers and employed, who know what they are discussing far better than outsiders can possibly affect to know." That of course is true, but then if employers and employed were always willing to discuss matters without passion, and to agree to concessions on this side and that suggested by equity, and supported by experience, there would have been no thought of giving a Court of Law power to decree a settlement.

Absence of Books.—According to the Registrar of the London Bankruptcy Court, "the absence of books has become quite a disease in his Court," especially in the case of foreigners. It is a little surprising that there is no statutory obligation upon traders in the United Kingdom to keep books. The Companies' Acts do not require books to be kept. The practice abroad is quite different. In Germany every trader must prepare an inventory of stock and a balance-sheet when commencing business and at the end of each financial year. The legal code enforcing this, which came into operation in 1900, gives detailed regulations for the books and accounts to be used in different trades and industries.

Hematite Iron Ore. — Attention was recently directed in these Notes to the supplies of hematite iron ore from the mines of the North-West of England, and to the efforts to find fresh deposits. In this there has only been partial success; but discoveries of important bodies of ore have been made, the most important finds lately made being at Lindal and at Ronhead. It is known that very large deposits of ore exist at Hodbarrow and at Ronhead, deposits which will take many years to work out. The deposits are believed to extend beneath the estuary of the Duddon, from Cumberland on the one side to Lancashire on the other. An effort has been made by the local and county authorities to come to an understanding as to the boundary line between the two counties, an important matter, seeing that iron mines are rated and contribute a large sum towards local expenditure. No agreement has as yet been arrived at. It looks as if the future supply of iron ore from the North-West of England will be mainly derived from this district.

The Cotton Industry.—Whilst the weaving from bought yarn department of the cotton trade is suffering in its profits from high priced twist and weft, the spinning part of the trade continues to earn large profits. Mr. Tattersall has given details of twenty concerns which issue particulars of profits and they work out at 30·44 per cent. per annum. The outlook continues on the whole encouraging, and it may be noted that the cotton industry on the Continent is in an exceptionally active condition. Even Russia is very busy, both spinners and manufacturers having for some months past experienced a brisk demand. In Germany the condition of the industry is highly satisfactory and the prosperity of the mills unprecedented. Stocks of yarns and goods are small, and a feature is that more East India cotton has been used this year. In Austria and Hungary during the past year there has been an increase of 50,000 spindles and 20,000 looms, mostly in Hungary. There are no stocks of yarns or goods, and prompt delivery commands a premium. Switzerland is very active; in France several mills have begun night work; in Holland looms have increased faster than spindles; in Belgium the outlook is encouraging; and in Italy the mills are working at their full capacity at profitable rates.

GENERAL NOTES.

NICKEL IN NEW CALEDONIA.—In his report on the trade of New Caledonia for 1906, Mr. Acting-Consul Manning refers to the production of nickel ore. Last year this production was 5,399 tons more than in 1905, but the value appears less, the reason being that in 1905 the ore for statistical purposes was valued at 45 francs per ton, and now is calculated at 30 francs only. Nickel ore could be produced much cheaper if the demand was greater, and sales of ore sure, as mines once opened would then be able to carry on, in place of which the rule has been that after some two or three years producers have had to throw all their men out of work, and wait for a contract before proceeding again, a system that would strangle any industry. The production for the past year was 57,367 metric tons, as against 51,374 metric tons in 1905. This industry in New Caledonia is at present virtually in the hands of one firm.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday Evenings, at 8 o'clock:—

MAY 8.—"The Production of Coke and its Application in Domestic Fires." By PAUL SCHLICHT. CORBET WOODALL will preside.

MAY 15.—"Trypanosomiasis or Sleeping Sickness." By HERBERT W. G. MACLEOD, M.D., B.Sc.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

MAY 30.—"Irrigation Colonies in India." By LAURENCE ROBERTSON, I.C.S., Under Secretary to the Government of India, Revenue Department. CHARLES EDWARD HENRY HOBHOUSE, M.P., Under Secretary of State for India, will preside.

APPLIED ART SECTION.

Tuesday evenings, at 8 o'clock:—

MAY 28.—"Sheffield Plate and Electro-plate." By SHERARD COWPER-COLES.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 6...Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, in the Theatre of the United Service Institution, Whitehall, S.W., 7½ p.m. Mr. Ernest Romney Matthews, "Waterworks Construction in America."

Chemical industry (London Section), at the Chemical Society's Rooms, Burlington-house, W., 8 p.m. Mr. O. Guttmann, "The Works Chemist as Engineer."

Surveyors, 12, Great George-street, S.W., 6½ p.m. Annual Meeting. (Junior Section) 7½ p.m. Mr. G. T. Loban, "The Case of the British Inland Waterways."

British Architects, 9, Conduit-street, W., 8 p.m. Annual General Meeting.

TUESDAY, MAY 7...Royal Institution, Albemarle-street, W., 3 p.m. Prof. W. Stirling, "Stimulation, Luminous and Chemical." (Lecture III.)

Alpine Club, 23, Savile-row, W., 8½ p.m.

Pathological, 20, Hanover-square, W., 8½ p.m.

Photographic, 66, Russell-square, W.C., 8 p.m. Mr. J. Watson, "Dry Collodion Plates with Preservatives."

Zoological, 3, Hanover-square, W., 8½ p.m.

East India Association, Caxton-hall, Westminster, S.W., 4 p.m. Sir Roper Lethbridge, "Imperial Preference, Cobdenism, or Swadeshi—Which is Best for India?"

WEDNESDAY, MAY 8...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. P. Schlict, "The Production of Coke and its Application in Domestic Fires."

Biblical Archæology, 37, Great Russell-street, W.C., 4½ p.m.

Royal Literary Fund, 7, Adelphi-terrace, W.C., 3 p.m.

THURSDAY, MAY 9....Iron and Steel Institution, 25, Great George-street, S.W., 10½ a.m. Annual Meeting. Papers to be read:—1. Prof. W. A. Bone and Mr. R. V. Wheeler, "The Use of Steam in Gas Producer Practice." 2. Messrs. H. Brearley and F. Colin Moorwood, "Sentinel Pyrometers and their Application to the Heat Treatment of Tool Steel." 3. Mr. A. J. Capron, "Induced Draught with Hot-air Economisers for Steel Works and Blast Furnace Boilers." 4. Mr. F. W. Harboard, "The Influence of Process of Manufacture on some of the Properties of Steel." 5. Mr. Joseph Henderson, "The Distribution of Sulphur in Metal Ingot Moulds." 6. Mr. Arthur W. Richards, "Steel Making from High Silicon Phosphoric Pig Iron by the Basic Bessemer Process." 7. Mr. Arthur W. Richards, "Steel Making from Pig Iron Containing Chromium, Nickel, and Cobalt." 8. Mr. D. Selby-Bigge, "Electrically-Driven Reversing Rolling Mills." 9. Mr. C. E. Stromeyer, "The Ageing of Mild Steel." 10. Mr Thomas Swinden, "Carbon-Tungsten Steels." 11. "The Nomenclature of Iron and Steel" (Report of Committee of the International Association for Testing Materials).

Royal, Burlington-house, W., 4½ p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Mr. H. F. Newall, "Spectroscopic Phenomena in Stars—I. Chemistry."

Electrical Engineers (at the HOUSE OF THE SOCIETY OF ARTS), John-street, Adelphi, W.C., 8 p.m.

Mathematical, 22, Albemarle-street, W., 5½ p.m.

Book-keepers', Cannon-street Hotel, E.C., 7 p.m. Mr. T. Mackworth Lucas, "The Elements of Bankruptcy Procedure."

FRIDAY, MAY 10 .Women Journalists (at the HOUSE OF THE SOCIETY OF ARTS), John-street, Adelphi, W.C., 8 p.m.

Iron and Steel Institute, 25, Great George-street, S.W., 10½ a.m. Annual Meeting continued.

Royal Institution, Albemarle-street, W., 9 p.m. Signor Com. Giacomo Boni, "Recent Excavations on the Forum Romanum and the Forum Ulpium."

Art Workers' Guild, Clifford's-inn-hall, Fleet-street, E.C., 8 p.m. Paper on "Velasquez."

Astronomical, Burlington-house, W., 5 p.m.

Clinical, 20, Hanover-square, W., 8½ p.m.

Physical, Physics Laboratory of the Royal College of Science, Imperial Institute-road, South Kensington, S.W., 8 p.m. Dr. T. C. Potter, "Stereoscopy with long Base line, illustrated on the Screen."

SATURDAY, MAY 11...Royal Institution, Albemarle-street, W., 3 p.m. Prof. W. C. McIntosh, "Scientific Work in the Sea Fisheries." (Lecture II.)

Journal of the Society of Arts.

No. 2,842. VOL. LV.

FRIDAY, MAY 10, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, MAY 15, 8 p.m. (Ordinary Meeting.) Dr. HERBERT W. G. MACLEOD, "Trypanosomiasis or Sleeping Sickness."

Further details of the Society's meetings will be found at the end of this number.

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

Tuesday afternoon, April 23; the HON. ALFRED DEAKIN, Prime Minister of the Commonwealth of Australia, in the chair.

The CHAIRMAN, in introducing the author of the paper, said that Dr. Hackett was a Member of the Legislative Council of Western Australia, and for many years had been a prominent figure in the national politics of the Commonwealth of Australia.

The paper read was—

SOCIAL AND ECONOMIC CONDITIONS IN AUSTRALIA.

By HON. JOHN WINTHROP HACKETT, LL.D.

The heading of my address this afternoon is the social and economical development of Australia. A large subject, but I hope my hearers may be reassured when I say that in the first place I desire not to repeat anything I have said in a paper I have just read elsewhere, and next with one exception I propose to confine myself to a few typical considerations. The exception consists of some statistics which however necessary for your information usually convey educational nourishment in the direct and most trying of forms. I trust they will not weary you, but Australia has just now so many critics, and seems in so many eyes to occupy the position of a suspect that the moment appears particularly fitting to give a few of the latest economic facts in regard to the rise of a colony, which, if we consider the date of its foundation, its earlier drawbacks, its geographical situation, and then look at its position to-day, one can say without hesitation presents the most marvellous example of successful colonisation recorded in any age and for any people. Perhaps this remark will prepare you for my statement that I am going to say little but what is good of the Commonwealth. I must add a word as to my obligations to Mr. Coghlan, the Agent-General for New South Wales, whose office has given me material help in collecting the statistical facts which I shall proceed to put before you.

Too many people, probably, overlook the fact that the Australian Commonwealth comprises more than 35 per cent. of the territory constituting the British Empire, and that with 97 per cent. of its inhabitants of English, Scotch, and Irish descent, it is the most purely British portion of the Empire outside the Motherland. Moreover, it has to be remembered that by far the great majority of those who emigrated to Australia were of a strenuous and hardy type, seeking scope for their energy and enterprise, which forms some explanation of the gigantic advances made in her settlement and in her industrial development.

POPULATION.

At the close of 1861 the population of Australia and Tasmania, exclusive of aborigines, was 1,165,183. In 1891 the population had increased to 3,240,531, and during the greater part of this period the country gained

largely by immigration. From 1891 to 1905 Australia gained but little from immigration, the growth of population to 4,052,474 persons being due principally to excess of births over deaths.

When the statistics concerning population and internal and external trade are compared it will be noted with interest that the years of the greatest prosperity in Australia have also been those when the country received the largest accession of population from abroad; and although, as Mr. Coghlan states, it cannot be said that the influx of population brought prosperity, it may fairly be said that the stream of immigration, induced by the prosperity of the Colonies, tended to keep alive and stimulate the conditions without which national progress on any large scale would have been impossible.

Our present population per square mile of territory is barely 1·50; several of the States have not yet reached the stage of one person to the square mile. In the most densely poputated State, Victoria, the population is still under 14 souls to the square mile.

Conditions of Life.

The excess of births over deaths is much greater than in the United Kingdom, the births totalling about 19 per thousand as compared with 12 per thousand in Great Britain, and the European average of barely 10 per thousand. The birth-rate for 1905 was 26·06 per thousand; the marriage-rate 7·20 per thousand, and the death-rate 10·81 per thousand.

Distribution of Population.

Except during the "fifties," when gold-seeking engaged the attention of practically the whole of the population of Australia, there has always been a tendency, and a growing one, for a large congregation of the population of the respective Colonies in cities and towns. At the beginning of 1906 the population of the capital cities was:—

Sydney....	529,600	of a total of	1,491,763
Melbourne.	515,350	,,	1,218,571
Brisbane ..	129,736	,,	528,048
Adelaide ..	173,235	,,	378,208
Perth .... (Including Fremantle)	80,000	,,	254,779
Hobart....	34,989	,,	181,105

The burden of production from the three principal primary industries—pastoral, mining and agricultural, valued at £96,500,000 per annum—is borne by about 600,000 persons, of whom some 70,000 are engaged in pastoral pursuits, 120,000 in mining, and 305,000 in agriculture. In the manufacturing industries about 275,000 persons are engaged, and the value of production in 1906 was £30,000,000; the total production from primary industries and manufactures for the year being nearly £140,000,000.

Compared with population, this amount of production is not exceeded, or even closely approached, by any country; and in regard to total value is surpassed only by seven States, the United Kingdom, France, Germany, Austria, Russia, Italy, and by the United States of America. And the return for the last fifty years from our wool and minerals alone amounts to almost double the National Debt of the United Kingdom.

Shipping and Trade.

The total movement of shipping—entered and cleared—from and to Commonwealth ports during 1906 was 30,406,049 tons, or 7·55 tons per head of the population.

In 1861 the tonnage was 2,425,148, or 2·10 per head of population.

In 1891 the tonnage was 12,235,213, or 5·07 per head of population.

In 1891 the tonnage was 26,198,899, or 6·89 per head of population,

compared with a total tonnage of 120,000,000 tons, or 4 per head of population in the United Kingdom.

The interstate shipping traffic of the Commonwealth amounted in 1905 to just under 23,000,000 tons. In 1861 the intercolonial tonnage was well under 2,000,000 per annum. In 1881 it was little more than 5,000,000 of tons, and in 1891 barely reached 11,000,000 of tons.

The exports to countries outside the Commonwealth in 1905 was £56,841,035, and the imports from countries outside the Commonwealth £38,346,731, showing an excess of exports of £18,494,304.

The total trade—imports and exports, interstate and external—of the Commonwealth in 1906 came to no less a sum than £170,000,000, about £42 per head of population, compared with a trade of about £20 per head in the United Kingdom.

During the last fifty years the pastoral industry has maintained steadfastly its supremacy as the chief source of Australian wealth.

	Value of Exports. £
1861	5,105,721
1871	11,882,736
1881	13,396,207
1891	20,461,877
1901	15,370,321
1905	19,814,924
1906	22,669,803

the value of the wool clips to date being £670,000,000.

In 1861 the sheep numbered	20,980,123
„ 1871 „ „	40,072,955
„ 1881 „ „	65,078,341
„ 1891 „ „	106,419,751
„ 1901 „ „	72,208,736
„ 1905 „ „	74,403,704

and at present over 80,000,000 sheep, chiefly of merino breed, are depastured on the natural grasses, and owing to the improvement of the fleece in quality and weight, the monetary return per sheep is now greatly increased. The total value of pastoral property, including land devoted to grazing, is about £230,000,000, and the value of stock alone is considerably in excess of £100,000,000. Since 1851 the output of wool alone has reached the total value of £670,000,000. Of cattle there were 8,525,295 in Australia in 1905, and 1,673,805 horses. In the dairy industry, which is expanding rapidly, 1,645,718 cows were employed in 1905. Of 140,868,726 lb. of butter made in that year 50,000,000 lb., valued at £2,447,134, were exported. In 1906, 75,803,862 lb. of butter valued at £3,242,174 were exported. The exports of frozen beef and mutton and sheepskins for 1905 were £2,919,018, and for 1906 exceeded £3,000,000. Timber, chiefly hardwoods, is now exported in yearly increasing quantities, and in 1905 £1,036,183 worth was exported, while the figures for 1906 show a considerable increase.

Coming to the area under cultivation, up to the present time about ten millions of acres, or half of one per cent. of the total area of the Commonwealth has been devoted to the plough. As will be seen by the following figures the expansion of cultivation has been more than a hundredfold during the last 25 years:—

Total area under crop.	Acres.
1861	1,269,042
1871	2,345,922
1881	4,489,607
1891	5,365,685
1900	8,813,666
1905	9,433,455
1906 .. approximate	10,000,000

It has been in the cultivation of wheat that the greatest advance has been made during the past 15 years, the area under this crop having been increased practically a hundred per cent., and at present over three-fifths, or 6,122,746 acres of the total of the cultivated land in Australia is devoted to the staple cereal; the return for 1905-6 being 68,520,772 bushels. Ten years ago Australia was an importer of breadstuffs; now the exports of wheat and flour, principally to the United Kingdom, are valued at over £6,130,000 per annum. In all the States the area cropped with wheat represents but an infinitesimal fraction of the area upon which this crop can be successfully grown; and as we approach a higher standard of farming, it may be expected that the returns from the land already cropped will be greatly increased, even if the present annual expansion of acreage be not maintained. From a commercial point of view, Australian wheat has won a topmost place in the British markets, and generally realises about 2s. per quarter more than any other wheat. The Australian farmer has, moreover, at his command vast areas of soil, within the regions of reliable and adequate rainfall, most effective and economical cultural and harvesting machinery, and 15,000 miles of State railways to carry his grain to market, and all combined with cheap and rapid transport by sea.

The acreage devoted to other crops for which respective regions of Australia are pre-eminently adapted is:—

	1905-6. Acres.
Maize	314,901
Oats (for grain and fodder)	466,567
Barley and other grains	135,798
Potatoes	121,762
Sugar cane	155,912
Hay (chiefly wheaten)	1,574,382
Vines	64,357
Orchards and minor crops	477,030

Although in general farm crops other than wheat no very considerable advance would appear to have been made during the past ten years, the prosperous development of the dairy industry has resulted in an enormous expansion of the areas of artificial pasturage. This is an important fact. In New South Wales alone almost a million acres have been already sown to grasses and crops of this description, and in Victoria even a greater area. The addition of these pastures to the natural sources of fodder, combined with the private and public systems of water conservation which

are being continually extended, will do much to safeguard the stability of the pastoral industries. The value of agricultural production in 1905-6 was £21,000,000.

Mineral Wealth.

The total mineral production of Australia to the end of 1905 was £633,737,302, of which

Gold represents	£460,397,288
Silver and silver lead	45,068,960
Copper	42,660,466
Tin	22,555,872
Coals	53,909,501
Other minerals, comprising practically all known minerals	9,145,215

The annual production is nearly £25,000,000, as under:—

Gold	£15 559,641
Silver and silver lead	2,861,604
Copper	2,274,766
Tin	1,106,208
Coal	2,337,504
Other minerals	882,612

Revenue.

The revenue of the Governments of the Commonwealth and the respective States exceeds £35,000,000 per annum, which is about a third that of the United Kingdom with a population ten times as numerous. In Australia, however, practically all the railways belong to the State, and the revenue from this source is nearly fourteen millions per annum.

The total revenue collected by the respective Colonies prior to federation was:—

1861	£5,464,188
1871	7,866,534
1881	16,591,547
1890-1	25,454,128
Since federation:—	
1900-1	£29,535,943
1905-6	35,760,520

If we take the sources of revenue for 1905-6, we find we receive from taxation—

Customs and excise	£8,999,485*
Other	3,445,112
Railways and tramways	13,624,347
Posts and telegraphs	2,824,348
Public lands	3,229,129
Other sources	3,628,099

* Of this the surplus above requirements for Federal services is returned to the respective States, *pro rata*, as under:—

New South Wales	£2,742,770
Victoria	2,097,119
Queensland	857,048
South Australia	539,879
Northern Territory	21,632
Western Australia	872,992
Tasmania	256,390
	£7,387,830

The expenditure, exclusive of loan expenditure, totals for—

1861	£5,744,903
1881	15,232,017
1890-1	26,790,034
1900-1	30,164,414
1905-6	29,731,885

Public Debt.

The greater portion of the public debt of the respective States of the Commonwealth has been incurred for the construction of railways and other revenue-yielding works. The following shows the use to which the borrowed money was put:—

Railways and tramways	£139,293,173
Telegraphs and telephones	3,771,663
Water supply and sewerage	30,266,977
Harbours, rivers and navigation public works, buildings, roads, and bridges	42,221,779
Other services	10,869,755
	£226,423,347

The annual interest (average 3·62 per cent.) and charges upon the public debt amount to £9,303,000, while the net revenue from works constructed from loan funds amounts to £6,554,000, leaving a net liability of £2,749,000 per annum.

The increase of Australian indebtedness may be traced in the following figures:—

1861	£11,300,940
1871	30,139,880
1881	66,306,471
1891	155,117,773
1901	204,952,075
1905-6	238,427,821
Total loan expenditure per head of population	£55 16 2
New Zealand	70 16 4

Banks.

In 1905-6 the deposits in the savings banks amounted to £38,789,889, and in ordinary banks to £110,905,269. The wide margin between the high wages earned by Australians and the comparatively low cost of living is strikingly reflected in the ever-growing ranks of depositors in the savings banks:—

Year.	Depositors.	Credit.
1871	100,799	£3,220,806
1881	250,070	7,893,464
1891	614,741	15,536,592
1900-1	950,079	30,869,591
1905-6	1,174,326	38,789,889

The average amount of £33 per depositor is not exceeded in any country, and the total

accumulation for the whole community stands unparalleled.

When it is remembered that in Australia a large majority of the working classes are members of some sort of provident institution, and that the proportion of wage-earners who possess houses and land is greater than is the case in any other portion of the world, it must be admitted there are grounds for holding that the prosperity of Australia seems as firmly based as it is widespread.

Railways.

Compared with population Australia is even better served with railways than the United States. There are now 15,078 miles open to traffic, and new lines are continually being added to the system of the respective States. The length of line is equal to about one mile for every 220 square miles of territory, and to every 275 inhabitants.

The growth of the railway mileage in Australia has been as follows:—1861, 243 miles; 1871, 1,030 miles; 1881, 4,192 miles; 1881, 4,192 miles; 1891-2, 10,394 miles; 1901-2, 13,821 miles; 1905-6, 15,078 miles.

The gross earnings of the Australian railways for 1905-6 were £12,807,787; working expenses, £7,540,535; leaving net earnings, £5,267,252.

The interest returned on the capital of £135,427,222 invested in Australian State railways is thus 3·89 per cent. Already the net earnings per train mile in Australia (2s. 11·37d.) compare favourably with the earnings of railways in densely populated countries, and as the Australian railroads serve millions of acres of territory not yet utilised to a fraction of its productive capacity, and are probably hardly equalled for the durability of materials used in construction of the permanent way, they form an asset involving low maintenance expenditure, one that can be relied upon to return an ever increasing revenue as the country becomes more densely settled and worked.

Postal Facilities.

The postal facilities of the Commonwealth are largely availed of. In 1905 the number of letters and postcards transmitted reached 322,774,634, being at the rate of 80·16 per head of population. When the enormous oversea and interstate trade is taken into consideration, it can readily be seen that the bulk of these letters constitute commercial correspondence. The growth of postal business may be seen by the following figures:—

1861....	13,564,265 or 11·75	per head of population.
1871....	26,040,035 or 15·53	,, ,,
1881....	72,278,616 or 31·64	,, ,,
1891....	168,907,355 or 52·70	,, ,,
1901....	239,560,717 or 62·98	,, ,,
1905.. .	322,774,634 or 80·16	,, ,,

The transmission of newspapers by post has increased in corresponding ratio, the figures for the closing year of respective decades, being:—1861, 10,211,469; 1871, 14,173,941; 1881, 41,486,973; 1891, 93,067,560; 1901, 117,584,798; 1905, 129,414,198.

In the matter of telegraphic communication, Australia is excellently served. In all there are at present 45,228 miles of lines throughout the States, and submarine cable communication with the Mother Country, New Zealand, and Canada. In 1861 there were less than 3,000 miles of line; 1871, 11,518; 1881, 25,604; 1891, 39,176; 1901, 45,108; 1905, 45,228. Since federation, the telegraph service in conjunction with the postal arrangements have come under the control of the Federal authorities, and telegraphic rates throughout the Commonwealth approximate those of the United Kingdom.

Education.

The youth of Australia enjoy educational facilities that compare well with those of any country. Illiteracy among the native-born Australians is practically a thing of the past, and adults unable to read or write are chiefly natives of other lands. Of State schools maintained from the consolidated revenue, there are 7,300, with 15,544 highly trained teachers. The net enrolment of scholars was 616,080 for 1905. In addition there are numerous private day and boarding schools which maintain a high standard, State technical schools and colleges, and nearly all the States enjoy the advantages of a university.

With the growth of population and the spread of education in Australia, serious crime, as evidenced by convictions at the Superior Courts, has greatly diminished, and so far as crimes of violence against the person are concerned, the Commonwealth enjoys an enviable reputation, the very small proportion of inhabitants of homicidal propensities amounting to statistical insignificance.

Some General Remarks.

It is time, however, to leave figures and take a glance at one or two special characteristics

of Australia, a country which took its first leap forward so recently as the middle of the last century, and which has succeeded so wonderfully in its efforts to draw level with the best results of older civilisations. What kind of land is this which has done so much in so brief a time? In the first place, in spite of the enormous returns from the soil, much the largest per inhabitant known to economists, let it not be supposed that Australia has travelled so fast and so far because her task was an easy one. We recall with pride the tales of the hardships endured in the work of exploration, of pioneer endeavour, of the gradual subjugation of a wilderness remote from its civilising base and often so refractory. But it may be the future has severer trials in store. Striking as is the record I have just laid before you, I can assure you we recognise that the business of fully adding Australia to the great civilisations of the globe is only in its infancy. We shall have to face many difficulties and allowances must be made for us. Permit me to take a few typical cases, say two physical and one political, the last one, the political labour question, over which Home opinion I fear is much against us. But over all difficulties whatever the Commonwealth is bound at any cost in the end to secure the victory. As to our physical troubles if you look at the map, you will notice that the population and closer settlement of the Commonwealth occupies a more or less narrow fringe of country. Save for a few exceptions this fringe not merely follows the coast but is confined to the extreme south of the island, and even that fringe is broken in the south by a wide stretch of close on one thousand miles of coast where settlement is hardly existent. Further, you will note that the source of the splendid contribution of produce made by Australia to the supplies of the world come from that fringe and from a comparatively slight broadening of it inland. You will notice a vast area probably equal to half of Europe, which is either only partially settled or wholly avoided. In this territory, which is not sterile but merely a wilderness, the families of British descent may be counted only by the score, and those families who expect to make of it a permanent home for themselves and their children are rather to be set down as units. Now, let there be no mistake as to the alertness of our sense of obligation in dealing with this huge vacant dominion. It is for the moment insufficiently utilised but our people well understand that there are going to be no spaces of the earth left waste which can possibly be applied to the service of man. Placed as we are at the very threshold of nations ready to overflow at any moment, with other European Governments looking for openings for expansion, lying in what is likely to be within a measurable historical period, the storm centre of the world's movements, the Commonwealth cannot fail to be alive to its danger no less than its duties. But what we ask is that we shall be given time and opportunity. Do not hurry us unduly; riddles await us in Australia in all directions.

The settlement of this territory may have to wait a little. Many problems, social, political, international, physical, are pressing on us, but that in this continent of experiments, this, one of the greatest of them all will not be ignored, of that our friends in England need have no manner of doubt. But why is this territory, the reproach of the present, left to become possibly the source of quarrel in the future. Why is it left idle? The fact is that throughout two-thirds of her dominion the Commonwealth has to fight or come to terms with two hostile forces unknown to the Motherland, the parching and persistent heats of long summers, and a characteristic scarcity of water. And to Australia has fallen, among all our self-governing communities the task of meeting, and if possible defeating these. Through all this great area these obstacles to the people taking full and beneficial possession of their great island, prevail with a severity well known to those who are still resolved if by any means it can be done, to add this two-thirds of their continent to the productive lands of the globe. It is perfectly possible, nevertheless, that this region may not be found to be adapted to the children of the men whose race has sprung from the chill marsh lands of north-western Europe. But if it be found that this is so the effort will no doubt be made. It is being tried on tentative lines by the present Prime Minister (Mr. Deakin) by drawing settlers from other nationalities. But that those settlers will not be of a coloured race is a foregone conclusion. It will be European like ourselves, and we may hope that if it be found a soil unsuited to British settlers, then from the more sultry lands of Southern Europe emigrants may come to whom the climate may prove more congenial, and who may lay the foundations of prosperous and comfortable homes for themselves and their descendants.

But with the heat there is even a worse enemy,

that of drought, and I dwell on these material obstacles in the way of settling portions of Australia, because a people may for the most part be judged and their future determined by the fight they make with the unfriendly forces of nature. Now, in many districts, even in those close to settlement, years have been known to pass without their receiving anything in the true nature of rain, nothing almost to damp the ground beyond a passing thunderstorm. But no Australian, any more than any one of yourselves, can be satisfied with the settlement of a country which largely consists of a coronet of great cities round a deserted rather than a desert interior. Yet we are bold enough to think that the menace which keeps the population to the coast will, year by year, give way to an incredible extent before the ingenuity and resolution of the Australian settler. What rain falls will be husbanded, running streams will be fully laid under contribution, artesian reservoirs are being tapped, even the bare sheets of rock or expanses of galvanised iron are utilised. Where all these fail we have, even in one case, turned back the winter floods of a stream that would otherwise have been lost in the ocean, and conveyed them for hundreds of miles at a cost of millions to water the arid interior. In a word, year by year we are encroaching on this barren kernel of the continent.

Do not let me, however, again omit to state that we have besides this arid centre tens of millions of acres of land fertile, well watered, genial in climate, still waiting for the axe and the plough ; but speaking in general phrases in regard to the settlement question, our three great needs are to prepare the land for the settler, to place and start him on his holding, and most difficult of all, to hold him there, himself and his sons. For we have to contend with that fascination, so fatal to the farmers' boys and girls, of the crowded city with its keener mental exercises, its perennial amusements, its chances of escape for ever from the monotony of the farm and the village. This is a puzzle of puzzles, not for us only, but for all progressive nations. How it will be met among ourselves it is not easy to say. The solution must be left to the free play of those indefatigable forces which animate and direct Australian life, with its promise of a readjustment of faulty conditions, its endless remedies for weak points in the social structure.

It remains to say a few words on a question which probably is exciting more interest in the Mother Country than any other social or political topic concerned with Australia—the action and the prospects of the Labour party in the Commonwealth. As you know, we have our parties, mostly replicas of your own, but our Labour party differs from yours, in that it is not only possible for it to rise to the Government of the State, but this result has been actually achieved in more cases than one. No party has been subjected to sharper animadversion, has even been a greater source of alarm, among the home critics,—and perhaps not a few individuals have deserved it,—than the party led by one of the sanest and most judicious of our politicians, Mr. Watson.

Now, I hold no brief for the Labour party ; I do not belong to it. But calm consideration may go far to discount the fears evidently felt in so many quarters. It is easy to take too censorious a view of the party and its true aims. It is only recently that the Labour party has acquired a position approaching command in any State. But lately it has all but secured a majority in the Federal Senate, due, I venture to think, not to numbers in its favour, but to the perfection of its organisation. In my opinion, it has yet to win the approbation of the majority of Australians, and much may happen before that majority has been converted to the extreme programme of labour views promulgated by the Caucus. We of the Commonwealth are subject to no panic terrors as to the political labour man and his works. Let us admit he is a Socialist. We cannot well call him otherwise when a foremost plank on his platform is the nationalisation of the means of production, distribution and exchange. But in Australia we have looked the Socialistic movement too squarely in the face to fall into any premature terror as to what the results may be. It has to be remembered that more than one cause has specially influenced in this direction the political thought of the Australian elector. I mention two ; the soil has been in all ages the seat of the more stable forces of the community, it is the seed bed of Conservatism, but almost from the first days of the grant of popular Government, the lands of the Crown were placed at the untrammelled disposal of the democracy. It was made the people's land to be treated as their will desired. And there was a second cause, the one great capitalist of the country, certainly the only capitalist who would accept the vast but necessary risks of the future, was the Government. Hence the conceptions both of omnipotent public rights over the land, and of the duty of the Government to see

no needed public work was wanting, fell completely into line with the predilections of the Socialist. That Socialism would run strong in the Australian blood might be expected in a land of wide social experiments; the intelligent and ambitious workman of American aims at lifting himself above his fellows by his personal endeavours. He is an individualist. The Australian dreams of using the powers of Government on behalf of his class, or as he calls it, the people; he is a collectivist. On all sides, too, he sees nationalisation in full play, not merely as you have it here, such as posts and telegraphs and the common defence, but in regard to railways, harbours, drainage and water supply, roads and bridges, municipal amusement, parks and zoological gardens, charity, regulation of conditions of labour in all employments, mines and factories, by land and by water, and in a host of directions as multifarious as they are regardless of past conventions.

There is little reason to doubt the sincerity of the Labour party when they claim that the aim which underlies all their efforts is to increase the wages, shorten the hours, and generally improve the conditions of the worker, but it is contended that they seek to achieve all this at the expense of another man's purse. Now I am not going into these vexed matters, either to question them or to approve them. I wish to draw your attention to the simple fact that a platform with which after all we, the Commonwealth, are the most concerned, excites so very much less perturbation in Australia than we find displays itself at home. Now, why, in regard to the politics of the Labour party, do we view aspirations and events alike with a calmness approaching confidence, even assuming that they are mistaken in their programme? Well, in the first place we remember that those who are making these social experiments, as well as those who are watching them, are after all the brothers and sons of the men who have shown themselves among the most practical of mankind, men who, if they find they have made a mistake, have been seldom long in retracing it. The Labour politician is just as keenly anxious to make a success of his life as any of those can be who are most convinced of the evil that this party is working. The political genius of the race is not dead simply because it has been transplanted to alien skies, and breathes in other seasons. Further —and we need not speak of interference with immutable economic conditions, for time only will show what laws are inexorable, and what only temporary and provisional,—all Governments who hope to retain office in Australia must both conform to and satisfy the demands of Australia on four main points —population, revenue, employment, and co-operative union with the Empire. If a party fails in front of any of these goals, its fall may be delayed, it cannot ultimately be averted. The Labour party are, therefore, standing at the bar of the same tribunal as those who are opposed either to their aspirations or their methods, and if the practical men of the advanced party find their programme untenable, there can be few things more certain than that they will lead the way as a mere measure of self-defence in readjusting their blunders. Moreover, we have had experience of Labour Governments. In Western Australia one was in power for a year and another held his Majesty's commission in the Commonwealth for a shorter period. In regard to both cases, I believe most will agree with me the actual administration was little to be distinguished from that of the ministries which preceded and followed them in State and Commonwealth alike. Perhaps they are safer under the responsibilities of office than with the guerilla freedom they may otherwise enjoy. There is no doubt one quarrel which we are not likely to make up with the Labour party; that which concerns the work of the "machine", as it is called—that caucus forge from which comes the inflexible and relentless instruction which seeks to bind the labour men in invincible chains, is, in my judgment, more likely than not to make ultimately for the electoral and political undoing of the party. It is not a weapon which the free men of Australia of any class are likely to add permanently to their arsenal. Nor do I hesitate to say, after seeing it from inside and outside in operation for an entire year, that, in point of fact the caucus system, when applied to the work of administration, has hopelessly broken down. Meantime it is well to recollect their great organisation and the loyalty of its members have given the party an influence out of all proportion to its numbers; if the men and women of Australia truly object to the domination of labour, they have only to leave their offices and drawing-rooms for a few minutes, and come to the polls. It is time to close these remarks. Will you allow me, however, to leave you with an appeal? I entreat of you to believe that the men of the Commonwealth are fully conscious of the great trust held by them primarily for the good government and welfare of their

own people, but to be further employed in promoting the unity and strength of the Empire, and that that trust, as splendid as it is responsible, will, as I am convinced, never be betrayed. But we ask some confidence should be placed in us. One of the greatest of privileges has been allowed us, that of administering a continent, we understand well that that privilege is the mother of even greater obligations.

DISCUSSION.

The CHAIRMAN said that the real audience which he hoped the paper would reach, namely, that which was not familiar with Australian affairs, and which was not able to appreciate all the work which had been put into Dr. Hackett's valuable paper, was not present in the building, but, in addition to addressing the audience, lecturers at the Society of Arts had the opportunity of addressing those who were not present by means of the publication of the paper in the *Journal*, and it was to them that he hoped the message of the paper would be conveyed. The author's cheerful reference to the admirably low standard of the homicidal propensities of the Australian people, was in his (Mr. Deakin's) opinion due to the fact that they would not listen to statistics, but probably there were many present of a mathematical capacity who would be able to carry away the real lessons which underlay the appalling tables which Dr. Hackett had most legitimately presented. The people of this country did not realise in any respect the relatively remarkable prosperity which obtained throughout the whole of Australia, nor the enormous wealth of that country and its inestimable opportunities. They did not feel that the great figures which were occasionally placed before them were the achievements of a mere handful of people, having relation to the great extent of country which required to be occupied, and consequently the ungrateful task which the author had undertaken, of condensing into the form of unanswerable figures the demonstration of the truth of his own assertion, was, and would be, a valuable asset among the many valuable papers which the Society had published. He hoped the paper would be widely circulated and closely read; it would bear very severe criticism, for the author was a practised writer as well as speaker, and had weighed his words well; in fact, he had been almost too judicial in his attitude, in order that he might relieve himself from the charge that he had unduly favoured his own country. Without being one of the seniors of the Commonwealth, he (the Chairman) was old enough to remember that the whole period of their history had been one constant process of disillusion, and disillusion of the most happy character. When Australia was first settled in New South Wales, the great doubt expressed was whether the country would be able to feed its own few hundred people, but now that country could feed a great part of the Motherland and its own millions as well. The country between the mountains and the sea, which was at one time considered utterly hopeless, and was regarded as a Sahara, and into which when men visited it they took their lives in their hands, now bore millions of sheep, and returned to the people millions sterling a year for the wool from which they parted. At that time the enormous extent of Queensland was a hopeless no-man's waste, which in his recollection men feared to confront, and men who invested their money there were thought to be entering upon a hopeless undertaking. But to-day there was no part of the British Empire which had greater prospects of every kind than Queensland. The author in one part of his paper described the interior of the Commonwealth as a barren kernel. He admitted the kernel, but denied the barren. Subsequently, in a very happy phrase, Dr. Hackett described the whole of it not as a desert, but deserted. A place could not be deserted which had never been occupied, because the occupation of a few aboriginals did not deserve that name. The fact was that the country was not a desert in any portion of it that had yet been reached, and the conquest of the country was advancing with greater rapidity in every decade. What the author had said about the tens of millions of acres of well-watered, rich land, which might be cultivated by ordinary European methods, was perfectly true. The great disadvantage of Australia had been, not only in its remoteness from the Mother Country, but in the fact that every one of its appearances was a living and actual contradiction of the appearances of this country. The people of England looked with pride upon their green fields, and very beautiful they were; and the men and women who went to Australia from England looked with disdain upon the brown grass fields, until they found that that brown grass would turn off cattle and sheep as fat as English green fields would. It took a long while to wear the superstition out of a man of English experience. The Australian emigrants came from a country in which the danger to agriculturists was too much water, and went to a country where the problem was how to deal with the least possible quantity of water. Then with regard to the mineral resources of the country, some of the richest gold-bearing strata in the world, which was found in that country, looked to the eye as if they contained no more gold than a piece of wood, and everybody, except a mineralogist, would have walked over such ores all their lives without suspecting that there was a grain of gold in them. The consequence was that in Australia they had from the start to the finish to fight against the inherited superstitions attached to the Old Country, which their fathers had brought with them from over the seas; and it was not until such things were swept out of their minds, and the test of actual experience applied, that the riches of

the country had been really discovered. Even in the last ten years the cultivation of the country had been revolutionised. In Victoria and New South Wales, land which could have been bought ten years ago for £1, and even in the more settled places £3 and £4 an acre, had now risen to anything from £6 to £8 and £10 an acre and upwards. The introduction of superphosphates and new methods of cultivation had added millions of acres to the grain-bearing territory right within the well-settled districts. In the same way settlers were now pushing out, with the advent of better water supplies, into what used to be called the "Never Never Land;" and he was assured by the people who lived there that they saw their way to carrying on the poorest of the soils what they had not dared to venture to expect to get on the best of them. What Australians had to face in the way of drought losses were due chiefly to their own fault—to an over-stocking of the country which its circumstances did not justify. They risked enormous losses when they plunged in pastoral affairs for great profits. If the land was worked with fair numbers, it could be worked with very small losses and certain profits; and it was partly because of the gambling instinct and partly of the greedy instinct, that losses had to be recounted, when periods of drought came, on the part of men who had multiplied their stock, and who had minimised the proper provisions they ought to make for watering their stock. Australia was a great country; he believed in it from the bottom of his heart, because every experience in his long life justified his faith in it. If there was desert country in Australia they had yet to find it; and, by a curious dispensation of Providence, where stock would not grow the soil was full of gold and other metals. He had it on the authority of two of the highest experts in the treatment of minerals in the wide world who had recently visited Australia, that in that territory there were greater supplies of minerals in sight, untouched, than in any other country in the world. Australia was a gold-producing country, but it also produced every other metal that could be mentioned. In the north-west there were those rare metals which were now coming into such demand for improving the quality of steel in connection with the lining of guns, metals of extremely rare value, because they were particularly rare, but which were bound to become more and more in demand, not only in connection with preparations for war, but in the triumphs of peace in the preparation of high-class machinery. There were larger deposits of those rare metals in the great North-West than in any other place yet known in the world. So that where Australia did not produce sheep, cattle, wheat and wool, it produced minerals. It could produce ten times more than it had ever yet produced, and that within a reasonable time if the population was forthcoming, if they were only content to learn the lessons of their own country, as the Australian people were beginning to do, and trust that every part of it could be made productive. Dr. Hackett alluded to the fact that Mr. Price and himself had made an agreement which handed over the great Northern Territory from South Australia to the Commonwealth, and that it would be undertaken as a Federal Territory. That was a mere trifle. The handing over of 500,000 square miles of territory, a tract bigger than the German Empire, was a typical Australian transaction. That land would be disposed of in one transaction, if Parliament endorsed it; and if the Commonwealth obtained it, the first thing it would do would be to carry out a scheme, which had been prepared in rough outline, for putting 5,000 families, altogether about 25,000 people, on the rich lands of the North which were capable of producing anything. The greater part of that tract was a plateau, where there were cool nights, and where it was possible to grow the finest horses and cattle in the world. He had been introduced to a man nearly eighty years of age, a nephew of Richard Cobden, who had spent his life on the York Peninsula, yet in spite of his age, he was strong, stalwart, and of a ruddy complexion; nevertheless it was said that the climate there was such that a white man could not live in it. There was nothing that Australians would not believe about their country when it seemed to reflect on its possibilities. He thought one of the great truths which had been illustrated in the author's admirable paper was the splendid financial position of Australia at the present time. It was doing an export trade of 20 millions more in the present year than in the first year of the Federation, six years ago, and the States were doing a trade of 26 million pounds more between themselves now that the Commonwealth was one industrial whole; the two items together meaning an increase in the transactions of the Commonwealth of 50 million pounds a year. With that record, what more could be wished for? There was an opportunity in the country for population, and it must be remembered that the country might draw other populations than British. A condition, however, was made in regard to every emigration proposal that it must be submitted in this country first, and the emigrants from other parts of Europe were only asked for and sent when the old stock could not be obtained. Australia had a certain control over contract labour, but it had no control over any white people, and sought to exercise none, who chose to come to Australia; they welcomed them from wherever they came, gave them the full rights of citizenship, and made no attempt to exclude any who might not be British if they were of European blood and breeding; but they hoped never to see them settle in isolated communities, speaking any other tongue than English, or attempting any other form of organisation. Australia wanted people who would stand with them, and that was why they came to Great Britain first. They began in England because of the ties of blood, and returned to this country again because they wanted men and women who were already fully equipped, not only with their inherent endowments of character, but with the traditions, the

habits, and the practice of the race which they prized and cherished, and from which they would not willingly depart. That was why they always looked to Great Britain first and last to obtain all the adventurous members they could; and he hoped Dr. Hackett's paper would be, as it ought to be, one of the active agencies in attracting to the shores of Australia as many as possible of those who desired to leave the Old Country.

Mr. Deakin being obliged to leave for an important engagement in connection with the Colonial Conference, Sir WESTBY B. PERCEVAL, K.C.M.G. (Chairman of the Colonial Section) took the chair.

The Hon. W. M. HUGHES (late Minister for External Affairs) said that Dr. Hackett's papers, like the doctor himself, were so very pleasant that it made the task of following him rather difficult, just as an enemy who met one with a pleasant smile, a cordial handshake and his arms full of presents, made it extremely difficult to work oneself up to that state of enmity which was desirable under the circumstances. He, therefore, found himself very loath indeed to say one word against the paper, as the author had treated the Labour party, to which he (Mr. Hughes) had the honour to belong very well indeed. Dr. Hackett had said that the Labour party would be a very decent organisation if it were not for one or two things, one of which was its platform, and the other its practice. But that might be said of almost anybody. For instance, it might be said of a man that he would be a very good Christian if he did not drink and would only believe in the Bible. In the same way, it might be said of the Labour party that they were good citizens, only, of course, they did not believe in their platform and their practice; their caucus and their methods were abominable. Mr. Deakin was in the position that he believed in their platform, but abhorred their practice. He (Mr. Hughes) did not know that it was necessary to defend their platform, but, so far as he had noticed, Dr. Hackett did not seem to know what their platform was. That, however, was nothing new, because it was always those who knew least about the platform and opinions of the other fellow who were the most effective in denunciation. Each party had a very large share of the truth in them, and if one could only see both sides, and was not too blown out with self-conceit, very much was to be seen which could be admired in the other man and his party. The author had said that the Labour party were Socialists. Personally he had fought an election, appearing on various platforms on the average three times a night, and during the whole of that time he declined on behalf of his party to be bound by anything more than the platform upon which they stood, and that platform was not a Socialistic one. The Socialistic party of the State to which he belonged denounced him very heartily, upset him tooth and nail, and did all they were able (which was very little) to bring him and the party to which he was attached down. It was quite true that another party said they were Socialists, namely, the party to which the author of the paper belonged. Mr. Reid, the leader of a party in the Federal Parliament, said they were Socialists, but nevertheless Mr. Reid for very many years was content to hail him as his brother, speaking most kindly to him and of him, and always made exceptions, in his fiercest denunciation of the party of men of the names of Brown and Hughes. Times had changed, and politicians changed with them. He supposed that maxim was known in England; if it was not, the people of this country did not watch very closely what went on. Mr. Reid had been in various positions in his time, and had now taken up, as he always did, a final stand, which they expected him to keep for quite a while. The author had mentioned the Labour caucus and its influence. A caucus might want defining in Australia; it did not in England, where every party had a caucus, and where every party that was in power had a party which was notoriously governed by its caucus both inside and out. There was another party in the House of Commons, the Irish party, which had its caucus, and moved like a machine in a mysterious way, but very effectively, and all the more effectively for being mysterious and moving like a machine. Doubtless the Conservative party and the Labour party had their caucus, too. The Labour party of Australia had its caucus, and thought that it was ever so much better to speak with one tongue than with many. That was discovered long before the present time. The people at the Tower of Babel spoke with many tongues, and the result, therefore, was not effective. As for the good the Labour party had done, and the evil that would live after them, there was no necessity for him to prove that the caucus rule, whether it be good or bad in principle, had been bad in result, because the author most effectually dispelled any idea in that direction. For the last fifteen years the Labour party had been a power, and for the great portion of that time it had passed really effective legislation. It had been said that the country was going to the dogs; but soon after Adam's time people arose and said that, and, when all the people who were at present living were dead and gone, some other equally foolish persons would arise and say exactly the same thing. The country had been going to the dogs to his knowledge since he was born, and it would go to the dogs in an equally satisfactory way, he presumed, long after he was dead. The result of the fifteen years of Labour domination in Australia was seen in the figures given by the author in regard to the advance in shipping, the general trade of the country, and the amount of money in the banks per head of the population. The figures showed conclusively that, whatever the Labour party had done, it had not been able to prevent Australia going ahead in such a way that no other country in the whole of the civilised world had been able to do.

The Labour party was accused of being a Socialistic party, and no doubt it was Socialistic if to be Socialistic was to try and lift up the people to enjoy a decent and respectable state of existence. If to put into cultivation five million acres in the last ten years was Socialistic, they had been Socialistic; if to tax unearned increment on land, on which certain individuals had done none of the sowing and did not deserve the reaping was Socialistic, they were in favour of it, and he understood that so respectable a man as Sir Henry Campbell-Bannerman shared the same opinion. It was said that all people were Socialists now, and to an extent they were. A number of the Australian Labour party might say wild and extraordinary things, but there were wild people in every party who said extraordinary things. The Labour party of Australia was not to be condemned for the sayings of one or two of its members, any more than any party was. The Australian Labour Party's ideal was to enable every man to get a fair opportunity of earning a living, and, thanks to that party, people could, in Australia, get in very many cases a better chance of doing so than in any other country in the world, and he ventured to say that the condition of the people was, all things considered, fit to be compared with the condition of the people anywhere else. Property was perfectly safe, interest was reasonably high, profits were good, and trade was very fair. According to the author they had had three good seasons, and he believed Providence was going to be kind enough to give them another. There was in New South Wales sufficient good land to keep fifty millions of people; it had a greater rain-fall than England, and in fifteen years out of sixteen was not visited by drought. Dairying, agriculture, and fruit culture could, and ultimately would, be carried out. But Australian people had to work. Neither his party nor any other party had a solution for the man who would not work. A loafer, whether he be a rich loafer or a poor loafer, was not wanted in Australia, but men who would work hard would get a good living. If people nowadays did not work hard and keep their eyes open they would be a failure in Australia, as they would be anywhere else. The figures given by the author spoke for themselves, and the fact that the party to which he (Mr. Hughes) belonged, had steadily increased in numbers, year by year, showed that it was not inimical to the interests of the country, and that on the whole, it was the party best worth trusting in the Commonwealth.

Lord BRASSEY, G.C.B., said that all present had listened to the paper with feelings of admiration for the marvellous wealth and prosperity of Australia. But there was something more than that to be admired, namely, the splendid qualities of the people by whom those resources had been developed. Mr. Deakin had described the appearance of the country, and those who had seen and travelled through it, knew very well that Australia would never have yielded her fruits to idle hands. There had been, and still were, many difficulties in the development of the country, but many of them had been overcome by the fortitude, energy and enterprise of those who went forth from the old land, and by a spirit which never surrendered to temporary failure or disaster, and which finally triumphed over all obstacles. They admired not only the result that had been achieved, but the qualities of the men to whom those results were due. Australia had been remarkable not only for the success which had attended its enterprise, but the country and its Government offered this country very useful object-lessons in many matters which deeply concerned the people, to which public attention was very properly being directed at the present time. Wages boards, old-age pensions, arbitration between employer and employed, were some of the things which were now occupying attention, and useful lessons might be learned from Australasian experiences. He was glad to know that it had been resolved to make inquiries on the spot, and to profit by the lessons which Australia had to give to the old country in these important particulars.

The Hon. Sir JOHN A. COCKBURN, K.C.M.G., thought it was impossible to say anything on the subject after a scholar like the author, a silver-tongued statesman like Mr. Deakin (one of the most sincere and earnest-minded statesmen he had met in his life), a protagonist like Mr. Hughes, and a nobleman like Lord Brassey had spoken, except that they all rejoiced as Australians that Australia had been put before the audience that afternoon in its clear and true light. When that was done, all the blue spectacles in the world would not suffice to dissipate the *couleur de rose* with which everything Australian was naturally permeated, because it was the land of prosperity and hope, in which the British race flourished better than it did in any other part of the world. That was the greatest possible tribute to the British race. If a tree were taken out of a nursery, where it had not room to develop, and planted in the open, very soon the full symmetrical development of its foliage would be seen; and when a Britisher was given a chance the analogy held good. In the people of Australia they saw as in a larger mirror the reflection of the features of the people of the Mother Country. With regard to the question of population, Mr. Deakin had referred to an arrangement arrived at with the Hon. Thomas Price, the Premier of South Australia, who was one of the Labour party, and who had done more statesmanlike things for South Australia than anyone who had held the reins of government there. The arrangement included the building of a railway across the continent, and it would not be long before another railway would be constructed connecting the Eastern States with Western Australia. Those two lines were absolutely indispensable to the development of the vast continent, and he thought there was no doubt whatever that, in their construction, sources of

wealth would be opened up which would remove once and for all the only reproach which could be brought against Australia—its deficiency in population. He believed that those two great works would attract population; and although every means had to be used to populate Australia with white people, it was a great deal better to draw them in than push them in. That was the true explanation of Dr. Hackett's statement, that in all cycles of prosperity there was an increase of population in Australia. With regard to the question of the legislation of Australia, it was both Socialistic and Individualistic. He gathered that the aim of Individualism was to secure to every man the fruits of the labour of his own hands; and he thought there was not a measure that had ever been placed on the Australian Statute-book that had not that aim and operation. One might call it what they liked, but he maintained it was individualism in the truest sense when the resources of the State afforded every man an opportunity of earning a living and enjoying the fruits of his labour; and that was the characteristic of Australian legislation.

Dr. HACKETT, in reply, said it would take a whole evening to deal with the points that his friend, Mr. Hughes, one of the fairest and most capable of the members of the Labour party, had made. He did not desire to say anything, except to thank the audience for the very kind hearing he had been given.

Sir WESTBY B. PERCEVAL, in proposing a hearty vote of thanks to Dr. Hackett, said all present would agree that they were much indebted to the author for his interesting and instructive paper, while a larger audience outside, who would subsequently read the proceedings, were equally indebted to him. He took the opportunity, as Chairman of the Colonial Section of the Society, of tendering its thanks first of all to Mr. Deakin for gracing the proceedings with his presence, and, secondly, to Dr. Hackett for his valuable paper The paper was, in his opinion, a remarkable testimony to what might be called the resurrection of Australia. Those who had been associated with Australia, and see the Australia of to-day and compare it with the Australia of seven years ago, if they had not known something of the recuperative powers of the country, would not believe that they were one and the same. The enormous strides which had been made in production and in wealth were astounding, and one of the great needs of the present day was a proper appreciation of the enormous growth which Australia had made in recent years. Growth was not confined merely to Australia, and very much the same condition of things was seen in Canada, and he hoped before very long, would be found in South Africa. He very much feared the people in this country did not understand the rapid development of the young nations, and the possibilities which were in the hands of the Empire in combining its resources.

The vote of thanks having been unanimously adopted, the meeting terminated.

Sir CHARLES MALCOLM KENNEDY, K.C.M.G., C.B., writes:—

The proceedings at the meeting of the Colonial Section on the 23rd April form valuable contributions to the records of the Society of Arts. Dr. Hackett's paper is an up-to-date statement relative to the social and economic condition of Australia, while the speeches of Mr. Deakin and Mr. Hughes afford clear and authoritative summaries of the views of Australian statesmen. The paper and speeches open out certain points which deserve further consideration. The position of Australia in connection with divergent international aims and policy in the southern seas is a matter of very real importance. The results of changes now going on in these regions will, in their final settlement, depend upon action taken in the island continent itself. Hence the policy of the several States, and of the Commonwealth, in matters affecting the position of Australia will have far-reaching consequences. The two main factors which must determine its position in relation to rival influences are money and men. Events may easily occur in which Australia may be dependent, for a time, on its own resources. Its population and available capital are disproportionate to the strength of States which may come into conflict with Australia; and for a time this disproportion may bear untoward consequences. Newspaper reports of local opinion and legislation render it doubtful whether the vital importance of encouraging immigration, and outside enterprise and capital is sufficiently appreciated. Present Australian ideals may confer comfort and enjoyment. But there is reason to fear, in the interest of Australia, lest conditions of temporary ease should in a period of conflict and stress place the country at a disadvantage. Then as regards the development of Australia, the caution of the late Sir Daniel Cooper, a member of the Colonial Section of this Society, should be borne in mind. The reports of experts and promotors may be correct within their literal wording. Yet there may be other facts which render them nugatory. "Good things" are usually taken up on the spot. Careful investigation is needed in regard to schemes laid before the investing public in this country. The action of Government in Australia is also uncertain. To cite an instance with which I am personally acquainted. Ten years ago steps were formally sanctioned by the Government of Queensland, and approved by the Colonial Office, to develop British New Guinea: if they had been duly carried out, much progress would have now been effected. Adverse feeling was aroused in Queensland, New South Wales and Victoria, and the sanction given to the scheme was withdrawn. I fully admit the right of an Administration to adopt an altered policy of this nature, if they are satisfied that the public interests intrusted to them require

this change of policy. But in this contingency, public faith and policy suggest equitable consideration towards the contributories to an undertaking which is at first sanctioned, and ultimately cancelled. The three Colonial Governments concerned, referred the matter to their Agents-General in London, who, if I am not misinformed, recommended a payment of £4,000 in settlement. The Governments, however, adopted the unusual course of declining to adopt the recommendations of their own Agents. And lately the Commonwealth Government, which seems to have taken over British New Guinea affairs, offered a new arrangement, which does not meet the case, and which is not acceptable on the money market. It would certainly seem the better course to accept, in principle at least, claims recognised as valid by the Agents-General, and to settle them without delay. To ignore a claim of this nature will imperil the credit of the Commonwealth. We may sympathise with, and admit the policy of a "white Australia." At the same time it is well to state, and to give attention to, various questions of policy and fact affecting the economic conditions and welfare of Australia. The true and permanent interests of the several States, and of the Commonwealth, will be served by careful consideration of all such questions. We must trust that the people will examine dispassionately their external and home affairs, and that their good sense will lead them to establish the bases necessary for the maintenance and the progress of their national existence.

TWENTIETH ORDINARY MEETING.

Wednesday, May 8, 1907; SIR STEUART COLVIN BAYLEY, K.C.S.I., C.I.E., Chairman of the Council, in the chair.

The following candidate was proposed for election as members of the Society:—

Smith, J. Landretto, Glenfield, St. George's, Grenada, British West Indies.

The following candidates were balloted for and duly elected members of the Society:—

Evans, J. W., Cobalt, Ontario, Canada.

Lee, William Harold, Sudan Railways, Shendi, Egypt.

Madunji, Pandoorung, 925, Bhandarwada-road, Dadur, Bombay, India.

Muntri, Narayen Govindjee, 192, Worlee-road, Bombay, India.

Rule, Thomas, Oceana Consolidated Co., Ltd., Kaombi, Chiromo, British Central Africa.

St. Quentin, F. G. de, British Consulate, Prague, Bohemia.

The paper read was—

THE PRODUCTION OF COKE AND ITS APPLICATION IN DOMESTIC FIRES.

By Paul Schlicht.

The honour you do me by your presence to-night impels me to ask your kind indulgence if it appear to you that I do not bring to my subject a knowlege co-extensive with its importance. I bring, however, the devotion of a close student of coal and its uses, the experience of a more than ordinarily zealous and industrious experimentalist, and the consciousness of having achieved a certain measure of success in devising simple methods of improving combustion that are daily contributing to the comfort of thousands, and to the economic use of fuel, in and about the city of New York. My recent activities that have had to do with the production of by-product coke for metallurgical purposes and the advocacy of the production of improved coke by gas companies, have led me to investigate the different methods of coke and gas production in the United States, England, Germany, Austria, and Belgium, with a view to finding the best and simplest methods.

Although I may seem to exceed the limits of my subject, I have touched upon other matters only because they seem to me to have direct bearing thereon.

I accordingly divide my paper into the following parts:—

1. The Use of Bituminous Coal.
2. The Production of Coke.
3. Kinds of Coke.
4. Application of Coke in Domestic Fires.
5. New Method of Combustion.

The Use of Bituminous Coal.

The impression vaguely prevails that the *per capita* consumption of coal is a fair criterion of a nation's rank in the world's civilisation. The truth of this statement, however, depends upon whether the use approaches the highest economic standards of the day, or, if not, whether the abundance of a country's coal resources excuses misuse and waste.

Applying these preliminary remarks to England, it does not seem to me, from the report of the last Royal Commission on the Coal Supply, that the validity of the contention of the late Professor Jevons, supplemented by the later more carefully statistical calculations of Mr. Price Williams, as to the early exhaustion of the coal fields of England, is materially affected. Yet raw coal continues to be "destructively" distilled, and, what is worse, the

lungs of the public continue to be impregnated with carbonaceous matter and sulphuric acid, attenuated, it is true, by the immense quantities of water, in the form of steam, that each little chimney-pot throws out. Why is it that only the wholesale industrial atmosphere-polluters are prosecuted and the equally guilty house-dwellers continue their more insidious, if homeopathic, air-poisoning unmolested? Let us look across the Atlantic. It can be truly said at least of the eastern portion of the United States, that the atmosphere is not blackened by domestic fires. Anthracite is the popular fuel, but latterly by-product coke has come into vogue in the communities where it is being produced.

Shortly after the adoption of bituminous coal as a fuel in England, a Royal Proclamation was issued forbidding its use, and authorising the destruction of the furnaces of the users, who were characterised as evil-doers. Scarcity of fuel it seems shortly compelled the resumption of its use. In the reign of Elizabeth, bituminous coal was again prohibited during sessions of Parliament, lest the health of the members should suffer thereby.

Hygienic objections to bituminous coal must have been gradually overcome in London, or the inhabitants must have grown more indifferent than in a simpler age, for deaths by the hundreds of thousands are traceable to the poisonous and fog-contributing exhalations its improper use gives rise to according to reliable chroniclers.

It must be said, however, that in recent years, thanks to the admirable and disinterested efforts of the Coal Smoke Abatement Society, and the exploitation of gas as a substitute for coal by the gas companies, the atmosphere of London is much less offensive than it was twenty-five or thirty years ago.

With your kind permission, I will introduce on the screen two photographs loaned me by the Gas Light and Coke Co., of London, showing the effect of chimney smoke on the atmosphere, the one taken before the lighting of fires in the early morning, the other some three or four hours afterwards. These photographs were taken from the roof of Cannon-street Station, and tell their own story.

For many years the smoke nuisance of London has really been indefensible. In Washington, the capital of the United States, there is no smoke nuisance. The owner of a furnace as well as the stoker are both liable to fine and imprisonment. This is full of suggestiveness for London. In New York until recently, practically a smokeless city, it is true that certain large fuel-users, feeling obliged to work their boilers to the bursting point, use bituminous coal on dark nights, and thus evade the lynx-eyed smoke ispector. The condition of the atmosphere the next morning, however, is tell-tale.

FIG. 1.

When one looks at a bright cheerful open fire, radiating its genial warmth, even though only a little way, into the room, one rarely stops to think what it is that is actually taking place.

The process we witness is aptly called "destructive." Yes, this coal, so laboriously extracted from the bowels of the earth, that men daily risk their lives to secure, that is

FIG. 2.

screened and picked and loaded in cars and vessels, unloaded by hand or ingenious mechanism, stored by the coal merchant, and made the subject of trusts and syndicates, how much of it in this wanton work of distillation is actually made to serve a useful purpose, and how much is destroyed or passes off as a polluting or fog-promoting emanation?

In addition to wastefully heating about fourteen times the air necessary to burn the coal and generously sending it out of the chimney into the open, together with enough water in the form of steam, impregnated with sulphuric acid, to produce a miniature fog, we destroy per ton of coal burned, as high as one hundred pounds of coal tar, countless constituents valuable in the arts and medicine, oils that give promise of success as the basis of illuminants and heating agents, and that are already being used for motor purposes as substitutes for petrol, as well as heavier oils, together with solids that can be employed advantageously in road-making and road improvements, in addition to their regular commercial uses; considerable quantities of ammonia, useful in the arts and invaluable in the form of sulphate of ammonia for agricultural and other purposes; cyanogen, in not inconsiderable quantities, either in the rough as prussiate of soda, or that may be converted into the various cyanogen products of commerce.

If this same ton of coal were used in the modern by-product oven there would be in addition to the products named, 14 cwt. of coke suitable for domestic and metallurgical purposes which improved coke can be made to serve a much more useful purpose than the raw coal giving in addition thereto at least 5,000 cubic feet of gas suitable for illumination, heating, and power purposes.

The poverty and inadequacy of these utterances respecting a popular use of bituminous coal, I fully realise when I consider the beautiful distillates that discovery and invention have enabled us to recover from this misused product of the sun's rays in the form of solids —crystalline and pulverulent of all the beautiful colours of the rainbow—liquids of varying specific gravities and boiling-points, gaseous constituents capable of many combinations. I leave this task to those more learned than I. The name of a great Englishman, Perkin, springs to the lips when this subject is adverted to. What a service he has rendered mankind! Small wonder then that the late Sir William Siemens (then Mr. C. William Siemens) in 1881 in an address before the Glasgow Science Lecture Association, declared:—"I am bold enough to go so far as to say that raw coal should not be used as fuel for any purpose." And this was before the advent of the modern by-product oven and its successful use in the manufacture of illuminating-gas and a high-grade coke!

I cannot conclude my remarks on the use of bituminous coal without quoting from the report of an address delivered at the recent annual meeting of the Coal Smoke Abatement Society at which the King's surgeon, Sir Frederick Treves, stated that he could personally say from what he had seen of the lungs of dead persons in London that they were absolutely black on the surface and down to their very depths; that the trouble caused by impure air was the starting point of serious diseases, and appalling misery that words could not portray. He added that the sooty substance blocked the lymphatic vessels and also the bronchial glands and lessened their power to resist disease, that the lung of the smoke-breather was already compromised, and that this appalling combination of soot and sulphuric acid was a great irritant to it; that all kinds of catarrh and bronchitis were produced by this matter, and catarrh was the starting point for more serious trouble in the chest. That fog would exaggerate to an intense degree all forms of lung trouble and killed Londoners not only by hundreds but by thousands. I was not present at this meeting and, therefore, quote from the newspaper reports this portentous warning.

Reverting again to the genial open-fire the passion for which would seem to warrant the designation of fire-worshippers to the Anglo-Saxon race. Are there not improvements at hand for using this raw bituminous coal, now so wastefully burned, that pollutes the air, contributes to fogs, poisons the blood, hastens death, and requires the dwellers of cities to make periodic pilgrimages to regions of purer air? Yes, or fuel that does not smoke, that will burn brightly, radiate more heat, last longer, can as I have before stated, be produced from this very coal if the gas companies in London and elsewhere in England can be shown the economic advantage to be secured by adopting the modern by-product oven so successfully employed in the United States. A high grade of coke of different kinds can be economically produced in such ovens, of varying degrees of density, porosity, and clean volatile matter, by merely varying the coking periods. Flaming coke for instance can be made in from four to five hours less time than the low volatile coke required for metallurgical purposes, a certain percentage of hydrogen and hydro-carbons that during the latter part of the coking period require much heat to expel, being allowed to remain in the coke. Coke for metallurgical purposes which should

have less than one per cent. of volatile matter can be made in the same ovens, thus supplying fuel for domestic, metallurgical, and other industrial needs.

THE PRODUCTION OF COKE.

Coke may be described as the carbonaceous residual of bituminous coals remaining after the expulsion, by heat, of the larger part of their volatile constituents. While its production between 1612 and 1621 seems certain, there is little reliable information as to who is really responsible therefor. Professor Jevons, relying on a work called "Metallum Martis," by Dud Dudley, natural son of Lord Dudley, containing accounts of the anthor's invention of the use of pit-coal for melting iron about 1620, and, later, of making coke from the small coals left in the pit, awards to Dudley the honour of having by this simple economic expedient laid the foundation of the iron industry of to-day. Records in His Majesty's Patent Office, however, cast doubt on these statements. In Patent No. 15 granted by King James in 1620 to Sir William St. John, Sir Giles Mompesson, Sir George Ayloff, Lewis Powell, Walter Vaughan, John Prothero, Henry Vaughan, Henry Stubbes, and Hugh Grundy, these patentees agree for themselves and their executors to pay for the privilege "the sum of five shillings for every ton of iron steel, brass, lead, copper, &c.," they may "make, fine, produce, or work by or with such charred fuels." The patent contains the following recital: "Whereas as heretofore upon the severall information first of one Simon Sturtevant and afterwarde of John Robinson made unto us, that they had found a way to "Melte produce, and make iron and divers other metalls and materialls with sea-coale, earth-coale, pit-coale, peat, turf, and brush, and such other like fuelle," a patent was granted them. The recital further states that this grant is cancelled, first, because the parties did nothing, and, second, because the method would be valueless "unless the coal be by some means corrected and purged from the sulphur or other contagious mixtures they contain;" but being informed by Sir John and others that "they have found ways and means to charke the several fuels of sea-coale whereby the same may be fit and serviceable as well for the uses aforesaid as well as other uses," they are granted the monopoly "to charke coal." Attached to the copy of these Letters Patent in the Patent Office Library, done into modern English, I find a paper that contains evidence that this early syndicate did not turn out as well as King James or the syndicate expected, for Sir Giles Mompesson, one of the syndicate that had agreed to pay into the Royal coffers five shillings royalty per ton of iron made, was, on the 26th March, 1621, degraded from the order of knighthood, the degradation "to occur whenever he shall be taken," his lands were declared forfeited, a fine of £10,000 imposed, "and lastly, he shall be for ever held as an infamous person."

The next patent has to do with coal products in which coke appears to be referred to as "cinders." I quote from it to show the then state of the coal products art. In 1781 there was granted to Archibald, Earl of Dundonald, a patent, for "A Method of Extracting or making Tar, Pitch, Essential Oils, Volatile Alkalies, Mineral Acids, Salts, and *Cinders*." (Italics mine.)

I summarise a portion of the patent. The coals, after being kindled, are enabled by their own heat and without the assistance of any other fire to throw off, in a distillation or vapour, the oils they contain. Persons doing this will be deemed to encroach this patent, because, as he avers the only means known until his new discovery was "a distillation of coal in closed vessels where the admission of external air was prevented and where other fuel and coal were required besides the coals contained in the closed vessel to produce the heat necessary to pervade the same." This patent was extended as the Earl had used up all his resources in attempting to put the invention into practical use.

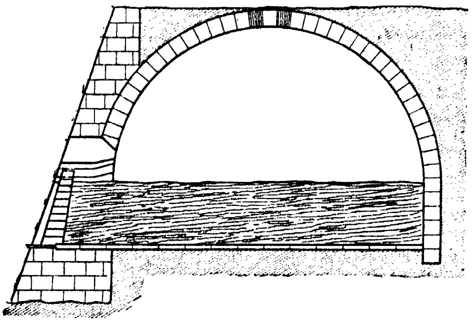
In 1783 Jean de Cannolle, described as "late of Paris but now of Piccadilly, London, Mineralist," obtained a patent for "a factitious coal to supply the use of charcoal more efficient in its qualities and perfectly innocent in its effects." His claim is, "The making, fabricating, or manufacturing of a factitious fuel by charring."

The production of coke in early times was doubtless due to the recognition of the advantage, as a concentrated heat producer, of a dense, hard, homogenous substitute for charcoal and pit-coal for the melting of iron. The process was called charking or coking, and was carried on in a manner analogous to that employed in the production of wood charcoal. The process passed through successive evolutions.

Whether coke be made in the primitive mounds, in ovens, heated wholly or in part by the gases evolved from the coal within the oven, or

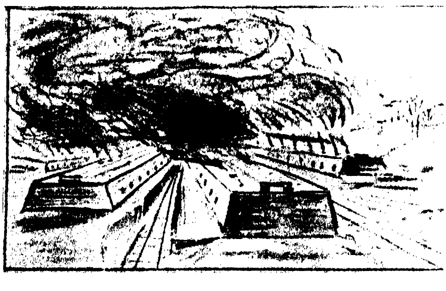
heated externally, the process as has already been stated consists, essentially, of the expulsion, to a greater or less extent, of the volatile constituents of the coal. The longer the coking period, heats being equal, the harder the coke and the freer it is from volatile matter. The latter portion of the coking period requires the expenditure of the greatest amount of heat. It required five to eight days to coke in mounds, it requires forty-eight and seventy-two hours respectively in Bee-hive Ovens, and the coking period in the modern regenerative oven has been reduced to twenty-four hours for metallurgical coke, and eighteen hours for domestic and industrial cokes which do not require the

Fig. 3.



Bee-hive Oven.

Fig. 4.



Bee-hive Oven Wastes.

complete expulsion of the gaseous portions of the coal, but are, in fact, preferable therewith on account of their flame-producing properties, greater porosity, and ease of ignition.

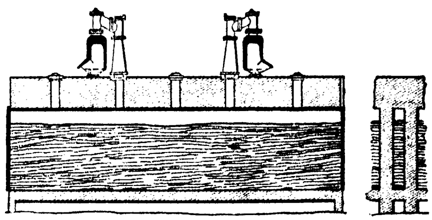
The art of making coke as practised to-day, consists, generally speaking, in the expulsion by the heat furnished in the burning of all, or a portion of the gaseous constituents of the coal, (1) within a coking chamber into which restricted quantities of air are admitted; or (2) heated externally thereby in a chamber from which air is excluded. The means for carrying out this art consists of ovens of fireproof material.

Ovens are roughly divisible into Bee-hive Ovens and Retort Ovens.

The Bee-hive Oven may be divided into (*a*) ordinary ovens in which all products except the coke are wasted, and (*b*) waste heat ovens in which the products are carried away by means of flues that their heat may be made to serve a useful purpose.

The Retort Oven may be divided into horizontal and vertical. The horizontal ovens may be divided into (*a*) non-by-product ovens, and (*b*) by-product ovens with horizontal or vertical heating flues. These may be further divided into non-recuperative and recuperative, and non-regenerative and regenerative. The vertical oven is a by-product oven, and

Fig. 5.



Retort Oven.

usually non-regenerative. The coal is fed into the top of the oven, and the coke discharged by gravity from the bottom of the oven. The charge is usually about two tons; the coking period with certain coals in as short a period as six hours.

The bee-hive oven is generally round, its diameter 12 to 15 feet, and its height 8 to 10 feet. The horizontal retort oven, which is the type of the modern by-product oven, has a long narrow arched coking chamber, with doors at each end, and may be from 30 to 40 feet in length, 18 to 22 inches in width, and 5 to 8 feet in height. In the bee-hive oven the coal is coked in a heap. Heat reflected from the dome ignites the coal. Coking proceeds from the top downward. The coke is quenched within the oven, and is withdrawn by manual labour. In the retort oven a long narrow high body is acted upon through the heating flues of the side walls. This narrow body is more quickly and effectively acted on than the large heap of coal in the bee-hive oven. Moreover, the charging and discharging of the coal can be done by machinery, and the coke quenched in the open. The coking period with the retort oven is shorter, especially where there are regenerators and coals that do not

readily lend themselves to the coking process, can, in the retort system, be compressed, moistened, and charged into the coking chamber in one long narrow cake, and produce coke of a quality impossible of production in the bee-hive oven.

The well-known retort ovens may be divided into those with horizontal and those with vertical flues. The type of horizontal-flued oven is represented by the Semet-Solvay, the Huessener, the Simon-Carvés and the Rothberg. The vertical-flued oven by the Coppée, Otto-Hoffmann, Otto-Hilgenstock, Collin, Koppers, and Von Bauer.

The vertical retort oven that deserves mention is the Appolt, first built about 1856, but generally superseded by the larger horizontal retort oven. Other vertical ovens are mere modifications of the Appolt.

The modern by-product oven seems to be the lineal descendent of the long narrow horizontal retort oven of which the Smet stands out prominently as a type. The Smet ovens were probably first built in 1848 and 1850.

Coppée in a large way, was practically the pioneer in the exploitation of the retort oven, by means of which coals that could not be coked in bee-hive ovens were made available for metallurgical purposes.

The father of Collin, inventor and constructor of the Collin oven, built Smet ovens in Germany as early as 1848.

Knab and Carvés used the Smet system in their by-product ovens, but the gas was insufficient for heating the ovens and coal or coke had to be used as an auxiliary heating agent. This gives some idea of the increased efficiency of the modern by-product oven and of the comparative efficiency of the by-product oven even as late as 1881, when Albert Huessener built his plant at Gelsenkirchen. The Carvés oven originated with Knab. Simon improved this oven and called it the Simon-Carvés.

In 1881, Dr. C. Otto experimented with Coppée ovens at Wattenscheid, Germany, "the heat being supplied entirely by cleaned gas, burning in flues surrounding the coking chamber." As a result, the firm of Dr. C. Otto and Company in 1881 constructed and exploited a form of oven in which the Siemens' Regenerator was employed to recover heat from the waste gases, and to supply heated air combustion, the oven construction being of the Otto-Coppée type, and generally known as Otto-Hoffmann oven.

There are differences of opinion as to the relative merits of the horizontal and vertical-flued oven that are due mainly to the question of the uniform-heating of the sides of the oven. The balance of opinion is in favour of the vertical it would appear.

My observation of the Huessener both at Gelsenkirchen and Middlesbrough satisfy me that for colliery and blast furnace use where surplus-gas is not important, it is an oven very well adapted to these uses.

Among vertical-flued ovens this may also be said of the Coppée and Otto-Hilgenstock, although Coppée, I understand, has under construction a regenerative oven intended to yield a large gas surplus.

The Otto-Hoffmann, the Koppers, and the Collin are the ovens which make substantial claims to producing largest yields of surplus gas and accordingly merit consideration in connection with gas production.

The adherents of Collin and Koppers claim much for their ovens, but the claim made for the new Collin oven is that it will give 10 to 15 per cent. more gas and materially shorten the coking period.

Otto-Hoffmann and Collin ovens have regenerators common to all the ovens. Koppers has separate regenerators for each oven.

In the Otto-Hoffmann and Koppers ovens one-half of the oven is heated directly, the other half indirectly. In the directly heated half of the oven the gas is burned at different points along the bottom of the vertical flues, the products of combustion rising in the one half descending in the other half of the oven, but heating that to only a moderate degree.

Alternate heating causes different differences of temperature; Collin proves that one half of such ovens to be always cooler than the other. In his latest oven which may be built higher than ordinary ovens he has methods for directly heating by contiguous vertical flues continuously from the bottom upward and from the top downward.

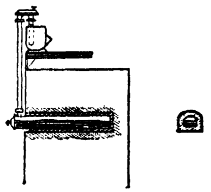
I must not forego proper mention of an interesting by-product plant I visited in Bohemia, at Wesseln, near Jeplitz, controlled by Imperial Justizrath, Dr. Aufspitzer, whose son-in-law, Herr Weiss, is the managing director. From the brown coal of that region, a very profitable industry is carried on in the making of coke for domestic purposes—coke of a high grade. The coal has about 35 per cent. of water. All the tar distillates are produced besides aqua ammonia, benzol, and gas for power purposes. The domestic coke finds a ready market, at a good price, in the large

cities. It is daily shipped. The oven is the improved Appolt; at this plant, the quenching is done without water. Another Appolt plant, for the same company, is being erected near by.

It will be seen that the coke-makers copied from the gas-makers. But the gas-makers have been thinking The recognition has tardily come that the larger units of the by-product oven, its greater life, the superior yield and quality of its products, especially its superior and varied cokes—domestic, locomotive, general steam-raising, and metallurgical—should long ago have impressed European gas-managers, especially after the excellent paper of Mr. Charles Hunt, now President of the Institution of Gas Engineers, read some twelve years ago before that Institution and the elaborate paper of Dr. F. Schniewind, read before the International Engineering Congress, 1901, so rich in reliable data, diagrams, and tables.

Coking is a carbonising process—so is gas-making. The processes in the gas industry of to-day are not as efficient carbonising agents as those employed in the modern coke industry, and generally speaking, the results per ton of coal carbonised in the by-product oven, of even low gas production, shows a more profitable carbonising system than does the older diminutive gas-retort system.

FIG. 6.



THE DIMINUTIVE GAS-RETORT.

Some of the foremost gas engineers and financiers of America are interested in gas-plants that owe their prosperous condition to the modern by-product oven. It is only fair to meet the objections that have been made by equally reliable authorities in England. They say they want gas—all of the gas. They want to have as little to do with coke as they can help. They may want all the gas, but do not get it. In a recent test made for me in America, it was shown that 25 per cent. less gas than was produced from an exceptionally good gas coal in the by-product ovens was produced in the modern gas retort. The average candle-power was also less, and the coke very porous.

A careful calculation shows that if all the gas for heating the ovens were added to the surplus gas, and the ovens were heated with coke or water-gas, or by-product producer-gas, the result would not be as favourable as if self-generated and automatically fed oven-gas were used for heating, provided always that a market could be made for the improved coke.

The economic advantages of the modern by-product oven were so well recognised years ago, as I have already stated, in America, that ovens were built near Boston in which coke is made, and all the gas to illuminate Boston and surrounding towns is manufactured. At Camden, New Jersey, some twenty towns are supplied with gas by the Camden Coke Company, controlled by the Public Service Corporation of New Jersey, gas being piped as far as Trenton, a distance of some forty miles. The gas for the city of Baltimore is made almost entirely in by-product ovens, and piped from the Coke Works at Sparrows Point. Both in Boston and Camden the exploitation of by-product coke has been very successful for domestic, steam raising, and metallurgical purposes. It has displaced anthracite coal to a considerable extent in many places, and is used successfully on locomotives and as a competitor of bee-hive oven coke.

KINDS OF COKE.

To the layman the word coke is a name applied to a product of the gas-works generally that has never been held in high esteem by those who use it, those who make it, or those who have heard of it; but this has been due in part to the ignorance of the best method of using it. Its porosity makes it bulk for bulk inferior in calorific value to the coal from which it is made, but of greater radiating power if properly used.

As has been seen, the bee-hive coke is very wastefully made, to the discredit of two such great industrial nations as England and the United States, 90 per cent. of the metallurgical coke being still produced in bee-hive ovens. The by-product oven is coming into favour with the progressive iron-masters of England, Bell Bros. Ltd., for instance, having done much to popularise by-product coke. In the late C. Lowthian Bell's paper read a short time ago before the Iron and Steel Institute of Great Britain, his favourable conclusions are given. I am greatly indebted to Sir Hugh Bell, the present head of the company, Greville Jones, works manager, and Dr. J. A. Roelofsen, manager

of the by-product plant, for valuable assistance in making tests with American coals.

If comparisons are carefully instituted between bee-hive oven and by-product cokes, it will be found that chemically the constituents are practically identical. Considered physically, the hardness and effective porosity of the latter makes it certainly equal, if not superior, to the former. The silvery colour of the bee-hive coke, due to a graphitic coating believed to protect the coke from dissolution by the hot gases of the blast furnace, is made up for by greater hardness and a more uniform porosity in the by-product coke. So great, however, is prejudice, even at this late day, and in the light of what is being done by the foremost ironmasters, that important industrial centres in England are still prejudiced against the use of by-product coke. In both cases the volatile constituents of the coal are either driven off or a portion thereof deposited to add to the bulk of the coke; in the one case, however, these gases are generally driven off into the open air and wasted, in the other they are saved. The fact is that, even if 1 per cent. of volatile matter should exist in bee-hive coke, it would be considered a disadvantage. The essential differences, therefore, in the two cokes is largely imaginary. In Germany and Belgium, with inferior coals to those of England and the United States, there are no bee-hive ovens, and the amount of iron produced per ton of coke, considering impurities in the ore, is authoritatively claimed to be greater than in England and the United States, a claim, however, that I have not had the opportunity of verifying.

In the modern by-product oven with improved uniformly continuous heating systems, cokes of varying degrees of hardness and inflammability can be produced in periods varying from eighteen to twenty-four hours.

The gas-retort coke made by nearly every gas company making coal-gas, is used for heating, steam-raising, and the production of water-gas, and, in London, in the cement industry. On account of its porosity and lack of uniformity it does not possess the fuel value, burned in the ordinary way, that it does burned with proper draft and special coke stoves, but grates have been constructed, and a furnace designed for burning coke with a long flame, invented by George Wilton, formerly an officer of the Gas Light and Coke Co., now Managing Director of the Chemical Engineering Company, which finds much favour with gas companies, and is capable of general application.

Application of Coke in Domestic Fires.

Sir William Siemens devised a system of burning ordinary porous retort coke in an open grate, in combination with gas, and introduced quite a number of these fires. Owing to lack of density of ordinary retort coke, I have been told, it has not found favour generally, the coke occupying nearly twice the space of ordinary coal, presenting disadvantages to the user not made up for by its advantages of smokelessness and of greater radiating power. Improved coke, of course, overcomes the objection to bulk.

The late Sir Charles Cookson, in a paper entitled "Smokeless London," described his use of gas in combination with anthracite and coke, showing conclusively the cheapness of gas for lighting fires in the place of wood, &c. Improved coke would, as a matter of course, work more effectively in this combination, which is simple and inexpensive. Grates and stoves made by several British manufacturers appear to be also well-adapted to the burning of improved coke, and from what I have seen of them in the burning of ordinary retort coke, I am of the opinion that they will work successfully. In the United States I have secured results both with ordinary retort coke and by-product coke that indicate that the physical and chemical change from raw coal to coke is a most advantageous one if the coke is properly burned. Coke in blast furnaces took the place of charcoal and pit-coal revolutionising the production of iron. I am confident that improved coke for domestic fires will revolutionise the fuel and gas industries.

The Royal Commission on the Coal Supply recommends central heating as a means of economising fuel. I beg to submit that coke fires can be kept all winter with a very small expenditure of fuel in simple central-heating systems that would keep ordinarily cold passages and rooms comfortably warm. The circulation of air in our dwellings should be as uniform as the circulation of the blood in the body of healthy persons. Nations that insist on this are neither weak or unheroic, and they have more days of real comfort than the less favoured, and are not obliged to go to the sunnier climes as frequently. Architects and heating and sanitary engineers are justified in studying this question. The Germans—those Yankees of Europe—are beginning to advise central heating on the score of economy. With improved coke and proper coke burners the efficiency of central heating systems will be

much improved. Public and office buildings, apartment houses, churches, theatres, and schools could be cheaply and comfortably heated with these central coke fires. The question will naturally arise, will the change of fuel—raw coal to improved coke—overcome poor grates, badly constructed chimneys, &c.? No, but those interested in selling improved coke should be sufficiently interested—and will be—to render assistance in remedying any conditions unfavourable to the burning of new fuel.

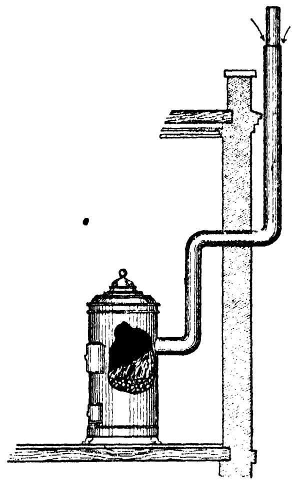
New Method of Combustion.

I shall now touch upon a new method of combustion, the principle of which I have suceeded in applying to chimney improvement and to coke-burning devices, and is also readily applicable to kitcheners, grates, steam boilers, and locomotives for improved coke utilisation.

In 1894 I made the discovery that in the accepted theory of chimney drafts certain factors had not been taken into account, for I had produced results regarded as paradoxical in view of Péclet's theory, the law of diffusion, and Tyndall's classic experiments on the diathermancy of air. My presumption was rewarded by prompt rejection of the Patent Office of my application for a patent on the ground that a patent cannot be issued to an inventor for "what to him is purely speculative," but that if I could establish my proposition by the testimony of disinterested experts or make a demonstration at the Patent Office, I would be entitled to broad claims for a new art or process of producing combustion.

The insufficiency of the current chimney-draft theory to explain the phenomena occurring in the closed stove shown on the screen is evident. This stove, as will be seen, is connected to a round sheet-iron smoke pipe, about 6 inches in diameter, and including joints, 25 feet in length. The smoke-pipe passed through an opening in the side-wall of the building in which the experiment was carried on and extended some 30 inches above the roof where observations could be taken A tube extending about 18 inches into the smoke pipe and 18 inches outside was centrally supported in such a way that an annular space equal to about 25 per cent. of the area of the smoke-pipe surrounded this short pipe. All the joints of the smoke-pipe were carefully cemented with asbestos cement as were also the joints and cracks in the stove; the fire was started in the usual way before the lower door was cemented up. The fire burned brightly for 26 hours and the economy in anthracite roughly considering comparative

Fig. 7.



Experimental Stove.

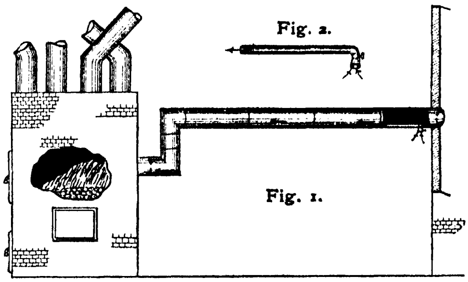
temperatures was fully 50 per cent. The observations made by me of the products of combustion passing out of the top of the short tube, and the descent of air through the annular space, indicated that experiments I had previously carried on with a small-sized cooking stove and a short chimney justified my contention that air and combustion products could be caused to flow in opposite directions in the same flue or chimney, the down-flowing air absorbing heat from the outgoing products of combustion, whereby the oxygen of the air more effectually acted on the combustible elements of the fuel in the place of combustion.

The Chief Examiner of the division of calorifics of the United States Patent Office, after witnessing demonstrations of the two oppositely moving currents, asked me to design a simple apparatus to carry out my process in his furnace.

The drawing I now show on the screen is a representation of Mr. Steward's hot-air furnace, which required one ton of coal per week prior to the application of the little air-tube to carry out the new principle I had discovered. This quantity of coal thereafter sufficed for 32 days to keep the house warm. This test was followed up by a number of others which convinced Mr. Steward of the validity of my claims. Mr. Steward's high standing as an

engineer and patent expert proved a great boon to the new invention. Subsequently, Professor Frederick H. Hutton, Professor of Mechanical Engineering in Columbia University, and Secretary for 25 years of the American Society of Mechanical Engineers, and Professor Morton, President of the Stevens Institute of Technology, as well as Dr. George H. Benjamin, American representative of the late Sir W. Siemens, gave the invention their warm approval.

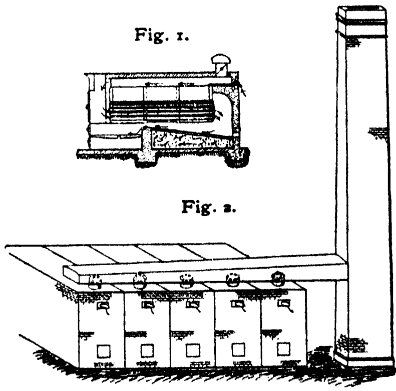
FIG. 8.



STEWARD FURNACE.

The New York Quinine and Chemical Works' boilers embody the same principle. I now show them with others to illustrate applications of the new principle.

FIG. 9.

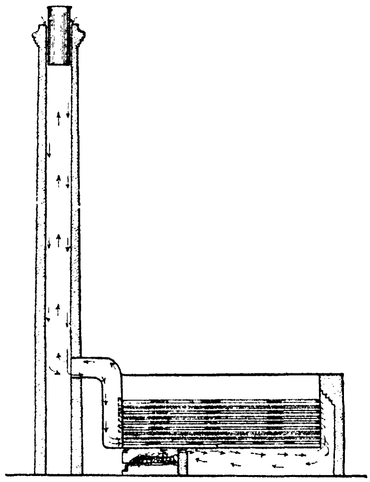


NEW YORK QUININE AND CHEMICAL WORKS.

It is perhaps due, primarily, to the late Russell Sage, of New York, who was largely interested in the gas business, and who saw in my improvements means for the better utilisation of coke for heating, that I seriously turned my attention to a study of the various systems of gas-making in the United States. But it was James W. Ellsworth, a large colliery owner, who first clearly saw the significance of the by-product oven in its relation to the gas and fuel industries, and who, after I had had to do with the testing of his coal in Otto-Hoffmann ovens actively encouraged me in going deeply into the whole question of coal distillation, and especially coke utilisation. Mr. Ellsworth personally made tests with coke for domestic heating with apparatus that I designed and estimated his saving over the best anthracite coal as reaching fully 40 per cent., proving that the supply of heated air furnished on top of the bed of fuel was even more favourable with coke than with coal.

This merely tentative experiment I followed up by a series of experiments in a laboratory I had fitted up for the purpose and in actual use for heating. All these tests show that

FIG. 10.



STEAM BOILER WITH AIR INSPIRTOR.

with my method of supplying heating air on top of the fuel instead of cold air underneath, coke, both retort and by-product, could be made superior fuels to the best anthracite.

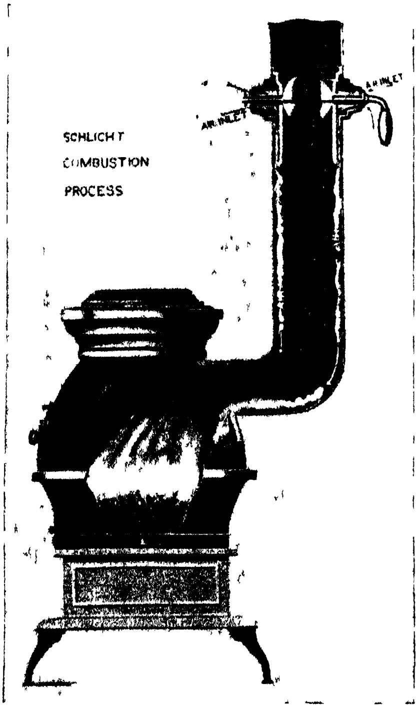
I believed, therefore, that I had achieved something that bore the same relation to coke that the gas-stove bore to gas and subsequent confirmation has been recently secured.

In kitchen stoves there is a great waste of coal. They also make their full share of smoke. The gas-stove has greatly obviated these fuel wastes, but in millions of homes raw coal continues to be used. The improved coke I have described if burned properly should produce not only greater economy, freedom from smoke, but also higher efficiency, particularly with this new process of combustion which is well adapted thereto. For the homes of the poor and those

who cannot afford the luxury of open fires my process will save fully 50 per cent. in fuel in ordinary stoves. In the burning chiefly of anthracite in and about New York there are some thirty thousand installations of apparatus embodying my principle.

I have frequently but reluctantly accepted invitations to read papers dealing with the use of coal from learned and inquisitive bodies in the United States—papers designed chiefly to

FIG. 11.



COKE AND ANTHRACITE STOVE.

promote discussion and question-asking—a highly developed American trait as some of you are doubtless aware; but in undertaking the task of reading a paper before the Society of Arts, whose audiences are wont to be addressed by men of rare gifts and deep learning, I have had grave fears indeed, lest my humble and unconventional efforts might suffer too much by comparison with more exhaustive and scientific discourses. But, supported as I am by warm friends and the enthusiasm of conviction, I feel both bold and strong in my zeal for the cause I am advocating, and I unhesitatingly predict that within five years the logic of events will bring about such reforms in the use of coal, that England instead of being the most spendthrift of nations—considering her coal supply—will reach the highest economic standards and provide the spectacle of a "Smokeless London."

FIG. 12.

CENTRAL AIR-HEATING COKE FURNACE.

I desire to express my heartfelt obligation for the courteous treatment and broad-minded encouragement I have received from Mr. Corbet Woodall, Governor of the Gas Light and Coke Company; Mr. Watson, the General Manager; Mr. Goulden, the Chief Engineer; and Mr. Goodenough, the Chief Inspector; also to Herr Paul Liebert, of Berlin, Managing Director of the Oberschlesische Kokswerke and Chemische Fabriken Actiengesellschaft, and Herr Altpeter, Local Director of the Zarbze Works; to Monsieur Brichant, Managing Director of Evence Coppée; F. J. Collin, Dortmund; and Directors Holbeck and Schmach, of the Actiengesellschaft für Kohlendestillation, Gelsenkirchen, for the privilege accorded me of testing coals in their ovens.

DISCUSSION.

Dr. J. S. OWENS, in opening the discussion, said he was particularly interested in that part of the paper which dealt with the device for improving the combustion in closed stoves. He gathered that the device was

applicable only to closed stoves, and to the combustion of non-smoking fuel. With reference to central heating, he thought there was some little difficulty as to whether it was an advisable thing or not. When a building had to be heated, it was not quite the same thing as heating people in the building. If one went into a building which was heated with warm air, one very often felt quite cold, although the temperature might be 60° or 65°, and the reason of that, he had no doubt, was because the heat was lost to the walls. Although the air of a building might be heated perfectly, the effect was not satisfactory to the individual. He thought one reason was that the convection of heat by air to the human body was extremely slow. The point was to compare that by heating with radiation by an open fire. When one sat by a fire which was radiating a large quantity of heat, one got hot very quickly. Another difficulty was the drying effect which central heating had on the heated air. It was also difficult to find a basis of comparison between the two systems; that is on what basis could they be compared? He would like to ask the author if he had any idea upon the point, because he found some difficulty in that connection when carrying out tests for the Coal Smoke Abatement Society. One basis of comparison which he had adopted was the cost—and everything boiled down in the end to cost in most countries—the cost in pence, per hour, per degree of rise F. in room air. He referred to domestic heating. He had some figures in his possession which were derived from those tests carried out for the Coal Smoke Abatement Society, under the superintendence of Dr. Des Vœux, and some interesting results were arrived at. In gas-stoves, stoves which had no flue, and in which all the products of combustion were passed into the room, the cost was an average ·095 of a penny, and in gas fires which had flues the cost was ·11 of a penny. On the same basis, with coal fires in open grates the cost was ·026 of a penny, and coke fires in the same grates ·037 of a penny. The figures must be considered as merely approximations; they varied slightly with different grates and fuels; but they gave a fair idea of the relative costs. He thought one of the difficulties with any smokeless fuel was that it was to a great extent flameless, and it was known that the amount of radiation from a luminous flame was very considerable. If one took away all gaseous matter from the coke, one took away all the matter which produced a bright flame, and a bright flame undoubtedly did produce a great amount of heat. That was one of the points that came out in the tests, namely that a fuel which produced a bright luminous flame heated up a room in an open fire much quicker than one which did not produce a luminous flame. With reference to the new method of combustion, that to him was one of the most interesting points in the paper. As the author said, it looked contrary to the result of what one would expect from a physical point of view, but he had no doubt that it was the cold outer surface of the flue which permitted of the down draught. He particularly desired to know the basis of comparison between the two systems? He knew there were numerous pitfalls. For instance, he had tried comparing fires upon the basis of the amount of heat given to the air; measuring the amount of air passed through the room, taking the temperature, and finding the amount of heat from the specific heat of air; but it happened that even if one doubled or trebled the quantity of air it did not reduce the temperature of the room, which was rather a remarkable result. He should like to see, if the author had them, the results of some comparative tests on stoves fitted with the apparatus and without. From the point of view of smoke he thought any suggestions which tended towards its abolition deserved very serious consideration, because it was one of the most crying evils of the day.

Mr. Greville Jones said he was interested in the paper more from a metallurgical point of view; what he wanted was a good metallurgical coke from which pig iron could be made. The author had brought forward a problem which he thought all citizens of London ought very seriously to consider. From a metallurgical point of view, there was no reason why all the gas necessary for London should not be produced in a by-product oven, and why, by producing gas in by-product ovens, London should not get an extraordinary credit from those by-products in the shape of sulphate of ammonia, which could be used for agricultural purposes, benzol, tar, &c., which were extracted out of gases. It seemed to him that there was no reason why coke made by that process should not be used for household purposes, in which case the atmosphere above London would be very much cleaner.

Mr. A. H. Louis said the methods the author had brought forward were not unknown in this country. Two or three years ago a person, whose name he had forgotten, brought to London a method very similar to the author's for use on tall chimneys. As explained in the paper, the reversal of draught could not be obtained in tall chimneys without a suction fan or similar arrangement. This gentleman, to get over the difficulty, had a mechanical contrivance for use in the top of the chimney. The arrangement apparently worked very well as long as the inventor had charge of it, but in other hands it did not; the stokers did not do their work properly, and the economy ceased. With regard to the author's arrangement, it seemed highly probable that drawing in the air from a small pipe would be sufficient; he had got a very large chimney to give the necessary draught. In ordinary slow-combustion closed-in stoves, such as were used in country houses, in which coke or any slow burning material was used, if every door in the stove was shut air came down the chimney.

It was a very slow process, and that was what was desired, and was exceedingly economical. That was without any particular arrangement at all, and sometimes—he had a case within his knowledge—when the pipe in the wall became rusty a better effect was obtained than when the pipe was not rusty, and that was unintentionally approaching very much to the arrangement of which the author had spoken. Therefore, for small stoves at any rate, it seemed as if the author's method was an exceedingly good one. Everyone knew perfectly well that if England were to accept American, French, or German practice for heating houses, any coke or anthracite, prepared by any method, could be used. As a matter of fact, a certain member of the House of Commons had suggested as a municipal enterprise that coke ovens should be built in a coal district, and that the gas should be brought direct from the collieries to London for heating and lighting purposes, which was scarcely a feasible idea. As the author had given such a good *résumé* of the origin of coke ovens, he would like to point out that probably the first coke oven for recovering by-products was erected in 1769, at Saarbrücken. Strangely enough, the poet Goethe, has also mentioned the furnace, and was much struck by the fact that there was a place where there was an oven, and that coal was being used, and that oil and gas was being separated from it, and, what was more, soot was being separated from it. The people in that district, which was a colliery district, sold the tar for lubricating purposes, and also the oil for use in lamps, and the soot for lamp black; but as there was no market for those things, the practice was abandoned. He had heard of a rather good experience in colliery practice in one of the collieries that the German Emperor wanted to purchase, in order that the German Government should have their own supply of coal. At the Shamrock Colliery they had two sets of ovens. That colliery had a very big by-product recovery installation, and also another which they were using under their boilers, and they came to the point where the cooling effect on the gases cost more than the by-products were worth, that was to say, in certain cases it was cheaper to take their hot gases direct from the ovens than to wash out the by-products. The point was that probably they were using poor coal.

Dr. H. A. Des Vœux rose to speak as a member of the Coal Smoke Abatement Society. The first photograph shown on the screen was of very great interest to him, because it was a similar condition of affairs which first made him take up the question of trying to abate the smoke evil in London. He was an early riser and had observed the condition of the atmosphere of London at four, five, six, and seven o'clock in the morning. It was most extraordinary to see the difference in the atmosphere between the hours of five and nine. At seven o'clock the atmosphere was extraordinary clear, especially in the summer, but at eight o'clock it was never clear. He joined the Coal Smoke Abatement Society at its inception some eight years ago, and he had been working on the subject ever since, more or less satisfactorily. He confessed that it was with the greatest satisfaction that he noticed that societies in London other than the Coal Smoke Abatement Society were now taking up the question. They, as a society, believed that the question only wanted to be tackled by a scientific man to be dealt with summarily for ever. It was only a question of chemistry and engineering combined to get rid of smoke in London, and surely the chemists and engineers of London were not going to be beaten by what really was a fairly simple problem. The burning of crude coal had been condemned for years, but still it went on; and he could not help feeling that the discussions which had taken place with regard to the subject would lead to more success than the Coal Smoke Abatement Society had itself been able to achieve. That society was not a scientific society; unfortunately they had been unable to engage the sympathies or exertions of the scientific world. He thought, however, the scientific world would take up the subject, because they would see that there was money in it. Money, he was afraid, governed people always, and fortunately he thought money would be on their side in the matter. There was an enormous fortune for anyone who could make fuel which would burn smokelessly in an open fire. He had had any amount of letters from inventors, offering him half-profits in inventions if he would sink money into them; but he could not do anything, as in the first place he could not afford it, and in the second place, if he could his position as a member of the Coal Smoke Abatement Society would be immediately compromised. It would not do for them as a society to have an interest in any particular process. He believed in the future there would be many processes carried out; but his society could do nothing more than report upon them. He did not quite understand whether the author's process was quite applicable to the open domestic grate; he rather took it that it was not. He was also perfectly convinced, from what he had seen, that in his lifetime, at any rate, people would stick to the open grate. He himself had had an almost closed anthracite grate in his dining-room for the last eight years. It was ugly, but it was very economical. It cost him no more than 2½d. to keep burning for 24 hours, and the chimney had never been swept since he had had it in the house. But he could only get two or three to follow his example. If the author's process was only applicable to closed grates, he did not think that he would get many followers in Conservative London. The author said his method was going to produce a better coke. He (the speaker) knew Sir Charles Cookson very well. Sir Charles was always preaching coke. He had seen coke fires, and they were very nice fires in their way, but they were not so nice as coal fires. He

did not think Sir Charles Cookson got anyone to follow his example. For some reason or other the people in London did not like a coke fire; whether it was the fault of the coke or the open grate he did not know; but he did not think the ordinary coke, as supplied by the gas companies at the present time would be used as fuel in London fires. He would be very glad if the author could say whether his new coke would be more applicable to the open grate than the coke of the past. He believed the gas companies could manufacture it, if they would try, but it was only in the last few years that the companies had been so trying. He approached one of the largest gas companies many years ago to try and interest them in the subject, but he failed. He said he wanted a smokeless house and asked the company to help him. They shook their heads and told him to burn gas. He said he could not afford to do that, and asked if there was no alternative? They replied that there was none. He hoped that the gas companies would, by force of competition, be driven to supply a new fuel, which would result to the advantage of themselves and to the City of London.

Mr. PAUL SCHLICHT, in reply, said he would answer in a few words Dr. Des Vœux's point as to the applicability of his process to open grates. Bituminous coal could be burned by his process in an open fire with certain modifications. The descent of the air was due to the fact that a vacuum was produced in an open grate. He had carried out experiments, and he could say roughly that fuel could be saved and smoke stopped, but he did not believe in the use of raw fuel, and the tests he had made in the United States had been chiefly made with anthracite coal and by-product coke, which he believed in. By-product coke, as made in the United States by companies that were supplying various cities with gas, produced a brighter fire than any fire he had seen in London, because of the fact that all the gas was not eliminated. As he had mentioned in his paper, metallurgical coke in the best ovens, at the present time, required twenty-four to twenty-eight hours to make, and domestic coke was being made in eighteen hours. That domestic coke had from 3 per cent. to 7 per cent. of volatile matter, chiefly hydrogen and certain hydro-carbons. The colour of the flame was not dirty; there was no dirt about the room; and one's face and collar did not get black. He had studied the tests made by the Smoke Abatement Society, which had been mentioned by Dr. Owens, and he was much impressed with the care with which they had been conducted. They had, however, been made along entirely different lines to the tests he had made. For instance, when the process was tested as to the amount of fuel that could be saved, either coke, by-product, or retort, thermometers were placed in eight different rooms of a house, and readings were taken every 15 minutes; the temperature of the outer air was also taken, and those results were compared with other tests without the device. The different local companies then went boldly forth, and said they would put the thing on a rental basis of so much a month, and if it was not found to be satisfactory it could be returned; and 97 per cent. of the installations put out on approval had been paid for. The man who occupied a room knew whether he was getting any benefit or not better than any thermometers could tell him.

Dr. DES VŒUX asked whether that applied to closed stoves.

Mr. SCHLICHT replied that it was a warm air heating apparatus, central heating. But he was well aware of the fact what an important matter it was to be able in England, where people liked to poke fires even if they were smoky, to produce a system that would effectually cure every chimney top; and from experiments he had made he was certain it could be done, but he did not wish to divulge further, as those matters were the subject of applications for letters patent. He had spent a good deal of time studying the question in this country. He made bold to say that bituminous coal, and by-product coke could be burned by the process by means of a slight change, not in the grate, but in a portion of the open fire, with a small device that would not cost, when made in large quantities, more than a smoke-jack that was now placed on top of a chimney. Experiments so far in the United States with a certain size of chimney gave great promise of that being a general success, but chimneys varied in sizes; some chimneys were made in Rumford's days to accommodate a good-sized sweep, and he did not know whether he would be successful in applying his system to such as those. With regard to by-product coke, bituminous coal, and anthracite coal, he had for three years carried on careful thermometric tests; not merely laboratory tests, but tests in the houses of leading citizens, physicians, physicists, and mechanical engineers, and he had not found what Dr. Owens had said was the case. It might be that the air was different in America. People did not get cold in a room that was properly heated with the right kind of heating appliances. American houses were very comfortable. By-product coke was the coke that gave the best results; it might be made a clean-flaming fuel. The very best anthracite in the United States—free burnt anthracite—flamed, but it was not a dirty flame. Why was it that iron-masters made a hard, concentrated coke, driving out the volatile products? They got more heat with that than with a coke that had 5 per cent. of volatile matter in it. It was so in a central heating stove; it was so in an open fireplace if the fire was once started with a by-product coke even without any gas in it. Those were practical results which had been

attained in the United States. No one there would think of using soft coal in an open fire; Americans were Anglo-Saxon enough to have plenty of open fires. They had open fires in every room, but they were auxiliary to a central heating system. They were ornamental, and were not relied upon for heat. He never found that he could stand 10 or 15 feet away from an open fire and get warm. He had been in England now for four months and had had already three attacks of influenza.

The CHAIRMAN, in proposing a hearty vote of thanks to the author for his extremely interesting paper, regretted he was not an expert on the subject, and he had only taken the chair in the absence of Mr. Corbet Woodall, who was to have presided, but who had telegraphed regretting that, owing to doctor's orders, he was prevented from being present. He (the Chairman) probably knew less about the subject than anyone present, but he did know enough to be aware of the enormous importance of it with regard to the health of the present and future generations. The thing that struck him most, apart from the suggestiveness and eloquence of the paper, was the rather sanguine expectation which the author had put forward, that five years would suffice to convert England to better ways. When he mentioned that the author, in his own paper, showed that the objections to bituminous coal and the attempts to make a decent substitute by coking began 270 years ago, it would be seen what progress had been made. Another point was that the author referred to the remark of Sir William Siemens that in his opinion, under no circumstances ought raw coal to be used. He (the speaker) however, presumed that our ancestors began with raw meat, and it must have taken very many generations of men to find out that there was any advantage to be gained in cooking meat; probably the first people who discovered those advantages were burned; and one might be quite sure that there were learned men in that time who thought society would go to pieces if meat were cooked. Apply that same theory to the use of raw coal. It had taken a great many years to arrive at the present point, and he was afraid that five years would scarcely suffice for the regeneration of coal fires. He thought it quite probable, however, in regard to industrial purposes generally, that the advantages of the author's system were easily observable; but in regard to the domestic hearth the author had to fight a tremendous prejudice. One gentleman that evening had spoken about the Englishmen who loved their open grates. He (the speaker) thought that if he had said English women, it would be more to the point. It would be very difficult to get English women to accept anything but an open grate. Consequently the line of least resistance was probably that suggested by one of the speakers, and accepted by the author, that of having an open grate with an improved fuel.

The vote of thanks was carried unanimously.

ARTS AND CRAFTS.

Wall and Ceiling Decorations.—The change that has come over the character of wall decorations of recent years must be apparent to the most casual observer. The difference is not merely in the kind of designs in vogue, or in the distribution of the ornament — though in both of these it is marked enough—but in the very materials employed. "Once upon a time," as the saying goes, it would have been safe to take it for granted that the ordinary middle-class house would be papered throughout—with the exception, perhaps, of distempered walls in the kitchens and servants' bedrooms, and a tiled dado, possibly, in the bath-room. To-day it would be dangerous to assume anything of the kind. It is not that wall-paper at any rate (whatever may be the case with old-fashioned distemper) is not largely and indeed universally employed. It is still, of course, the staple wall covering; but, not only have the different kinds of paper increased in number, but they have been supplemented by various other materials, either new in themselves or only recently used for wall decoration. Only a few years ago, to find the passage walls of a London theatre covered with coloured linen or canvas would have created quite a sensation, and the idea of a coarse canvas dado, painted and varnished, would have met with an almost derisive reception from most people. Yet neither of these things so much as calls for comment to-day. We take them as a matter of course.

Self-evident as the change is, it was none the less somewhat of a surprise to visit the Building Trades Exhibition at Olympia. The show, in its new quarters, was on so much larger a scale than it had ever been before, that it afforded a far better opportunity than usual for the study of what is being done in the way of trade decoration. Perhaps the most noticeable thing in the whole Exhibition was the apparently never-ending variety of materials for decorating the walls and ceilings of houses. The first thing that strikes one about the numerous paints, &c., is the ugliness of their names which are chiefly formed from some quality they are supposed to possess with the aid of a suffix. Still the quality of the names pales before their quantity. Time was when enamel paint, to the unitiated, at least, seemed to be synonymous with Aspinall. To-day we have a whole collection of different makes, to say nothing of ordinary paints in goodly number, and a formidable array of water paints and washable distempers. The makers of these last have shown their enterprise at the Building Trades Exhibition. Messrs. Sissons (who make Hall's Washable Distemper) erected a bungalow which they decorated entirely with their various paints, and the Silicate Paint Company, not content with covering the inside and outside walls of a model cottage with "Duresco" have shown numerous specimens of hand-painted decoration executed in their paint.

Additions have also been made to the more durable

kinds of wall coverings. Anaglypta and Lincrusta (neither of which, by the way, had a special show at the exhibition) are, of course, quite old friends. The various sorts of metal decoration are of more recent invention. Messrs. Essex and Co. are now producing an enamelled metal wall covering, and the "Emdeca" decorations, enamelled on zinc sheets have been with us now for some ten years. At the present time, instead of confining themselves to simple geometric tile-patterns, the makers are producing all kinds of floral and other designs. Their effect in the distance is rather puzzling. As a rule there is something about a design which reveals the process by which it is executed—one knows more or less instinctively that a certain pattern is executed in tiles, say, or in wall-paper—but there is a want of distinguishing character about these enamelled metal designs, which makes it difficult to guess what they are for, while the surface of the material, not quite like either tiles or varnished paper, again does not help us. A new departure introduced by the "Emdeca" Company is the "Steleonite" stamped steel ceiling decoration. This is made of Bessemer sheet steel, stamped with patterns in relief, and is intended to take the place of plaster ceilings. Of course, the effect *in situ* is not quite the same as that of a plaster ceiling—but the material in its own rather different way gives all the relief that is required for the purpose. It is claimed that these various metal wall and ceiling coverings are now quite simple to fix, aud that when properly put on, they keep their position for years.

There was not a very representative collection of wall tiles at Olympia. Messrs. Mintons, Limited, had a small exhibit of enamelled tiles, and Messrs. Carter and Co. showed some wall panels, while the sides of Messrs. Doulton's bath-rooms were covered with plain coloured tiles of not unpleasing colour, surmounted in one case by a landscape frieze. The other well-known tiles firms were unrepresented. Glass tiles, however, which are a much newer form of wall decoration, and not so well known—which have, in short, their way to make in the world, were comparatively speaking much better represented. One firm, the Hygienic Glass Tile Company, Limited, showed some really very ambitious work in the way of panels made up of six-inch tiles painted with birds, landscapes, &c. Some of those painted under the glass are very interesting and suggestive in effect. Taken on the whole, however, the quality of the surface of the glass tiles is at best unpleasing. That may be because we are not yet properly accustomed to it.

To see so many media for wall decoration mixed up more or less indiscriminately with woodwork, metal casements, kitchen ranges, sanitary appliances, or what not, is somewhat bewildering. It is difficult to disentangle them and to compare their respective merits. For all that they leave the careful observer with a distinct impression that crude, banal, unsatisfactory as some of them may be their general artistic level is higher than it was some years ago.

Fireplaces.—Some wiseacres are never tired of telling us, if not that "there's nothing new and nothing true and it doesn't signify," at least that there is no such thing as a really new fashion—that fashion, like fortune, simply turns her wheel, and in so doing brings us—not to something new but to something different from what we have just been looking at. And, however much we may resent being told so, we cannot deny that there is more than a grain of truth in what they say. At the present time it is being exemplified with regard to fireplaces. Ten years or so ago it was pretty generally taken for granted that the old iron fireplaces had gone never to return. (In many if not most cases, of course, the skeleton of the surround was still made of metal, but that only served as a kind of framework to the tiles which, from a decorative point of view, made up the fireplace) Of course in one sense they have altogether departed. We no longer see small houses with heavily ornamented iron grates (though, by the way, gas stoves have a good deal of not very beautiful ironwork about them sometimes) which want continual blackleading to keep them in good condition, and look singularly out of place in summer filled with art screens or beribboned pots of flowers instead of with coals. We are not likely to see them. The inhabitant of the small house has no time to spend on cleaning such things, since he (or rather she) has learnt that tiles may be much prettier, and are certainly much easier to keep in good order. For all that, in another quarter, and in a somewhat different form, iron fireplaces are again making their appearance—and that not as a new departure, but as a part of the general movement towards Georgian decoration. There is very often a good deal of trouble involved in fitting and arranging the tile surrounds of fireplaces—and it is natural that the metalworker should not let so large a portion of his business fall unreservedly into the hands of the tilemaker without a sturdy fight to recover lost ground. Some years ago, he hit upon the happy idea of reproducing the old Georgian fireplaces (slightly adapted, of course, to fit the new grate shapes) not, indeed, in steel but in iron brought to a steel finish. The production of these metal fireplaces has gone on growing, and quite a number of them were exhibited at the Building Trades Exhibition this year. They are practically all reproductions of old designs, but they are many of them very tasteful—notably those shown by the Carron Co.—and when properly polished, look both attractive and dignified. It is only after some reflection that one realises how much keeping bright they would take, and how impossible it would be to adopt them in any house not carried on with a certain amount of style, and an ample staff of servants.

Again, in this section, the tilemakers were not very much to the fore at Olympia. Of course, there were a good many tiled surrounds, hearths, &c.,

included in the shows of the various grate makers, but the only manufacturers who show independently are Messrs. Carter and Messrs. Doulton. This last firm exhibit one adaptation to this purpose of their Carrara stoneware—a substance which has hitherto been used chiefly for outdoor work. Their small mantelpiece in coloured salt glaze stoneware is also an interesting bit of work. On the whole, however, there is very little that is fresh in the way of tiled fireplace decoration.

If we somewhat extend our field of vision and include the overmantel in our estimate of the effect of the fireplace, the most noticeable feature in this year's exhibition was the number and tastefulness of the wooden mantelpieces. Not the least satisfactory of these are those with simple, rather rigid outlines, and into some of them simple inlay work in the form of a border has been introduced with results as pleasing as they are unpretentious. The restraint and repose of some of the mantelpieces and overmantels at Olympia was really a very welcome change from the rather fussy erections of which we have all seen so many of recent years.

CORRESPONDENCE.

THE PROTECTION OF SEA SHORES FROM EROSION.

I should like to draw attention to some groynes about to be put in at Roedean, near Brighton, for the Brighton Sewers Board and the East Sussex County Council. These bodies have selected a type of groyne which, in my opinion, fulfils all the requirements mentioned by Mr. Carey and also Professor Boyd Dawkins. It is a low groyne, is easily raised as the shingle accumulates, costs under 20s. per foot run according to the accepted tender, and is composed of an immensely strong and practically indestructible material, *i.e.* ferro-concrete, or reinforced concrete.

The piles are 16 inches square, grooved on two sides, placed about 5 feet 6 inches apart, and in the grooves are placed slabs of ferro-concrete 6 inches thick, each slab being 12 inches high; these are dropped in the grooves as the shingle accumulates, and the groyne requires raising; the higher piles will be supported by struts of the same material as the piles and slabs, and being much heavier than wood, there is no tendency to "lift" with the waves. The cost per mile of coast for these groynes is, approximately, £5,000.

One of the chief advantages being that the first cost will, in all probability, be the only cost, as the material hardens with age.

As regards the binding quality of the sea-grasses on the shores of Lord Montagu of Beaulieu's estates in Hampshire, I can speak from unfortunate experience, having been almost drowned by entanglement with them whilst bathing, near Calshot, some years ago. I can strongly recommend their cultivation on a sandy coast liable to erosion.

ROWLAND H. HALLS.

Lewes, Sussex.

There are many statements in Mr. Carey's paper with which I am unable to agree, and as accuracy is of the first importance in dealing with such a subject, I will refer briefly to some of these. Mr. Carey states that "the Woods and Forests Department have control of the foreshore." The Crown Lands Act of 1886 transferred the control of the foreshore from the Woods and Forests Commissioners to the Board of Trade.

Turning now to Mr. Carey's reference to changes in the relative level of land and sea, I will not go further than to say that the existence of the Continental platform is evidence of an almost universal rise of sea level, or subsidence of the land, so overwhelming as to be beyond dispute.

Now as to the explanation offered by Mr. Carey, I refer to the locking up of ice at the poles. A short consideration will show that this is inadequate. As long as the ice is floating, its existence will have no effect on the sea level, since when melted it would simply supply the same amount of water which as ice it displaces. We are, therefore, limited to land ice. I have calculated roughly that if the ice on all the ice-bound land in the world (assuming also an ice-bound Antarctic continent) were melted, for every foot of ice we should get a rise of sea level of 1-18th of an inch. To account for a rise of 600 feet in sea level, to cover the Continental shelf, we should, therefore, require to melt such a sheet of ice of about 24 miles in thickness, which I think is rather more than was available. We should remember that since ice melts under increased pressure, there is a limiting thickness beyond which ice cannot exist. It is interesting, however, to note that the evidence of recent Arctic and Antarctic explorers shows that the ice at both poles is now rapidly melting, so that we must now be experiencing a steady though slight rise of sea level, due to the water from this melting ice.

As to there being no other explanation of a great rise of sea level, it is far more probable that the rise was due to some sub-oceanic disturbance resulting in an elevation of a large area of the sea bed.

Turning now to Mr. Carey's diagram illustrating what he calls the "normal line of travel of a particular pebble on a beach," he says the pebble is driven up obliquely to the shore line by the impact of oblique waves, but returns in a path at right angles to the shore line, thus repeating an error made by Wheeler, and some others. The mistake lies in the fact that the path of the pebble's return is not at right angles to the shoreline, but oblique. When a projectile is thrown

through the air, it describes a path which is practically a parabola; the horizontal motion being uniform, or nearly so, and the vertical being retarded or accelerated in proportion to the square root of the height travelled through. Similarly with a pebble driven obliquely up an inclined place, such as the shore. The oblique motion may be resolved into a component at right angles to, and one parallel to the shore; the former is gradually destroyed and reversed by gravity, the latter continues, being merely retarded by friction. The same law which governs the flight of a projectile, governs the path of the pebble, the component at right angles to the shore being retarded, or accelerated as the square root of the height the pebble rises or falls; the alongshore component remaining nearly uniform. The only difference being that for g, we have $g \sin i$, i being the angle of inclination of the slope; and for air resistance and friction, we have friction on the bottom.

Relative to sea-walls, I can only say that a wall having a vertical face, such as Mr. Carey recommends, would, in my opinion, be a serious menace to the shore. It is the almost universal experience of sea-defence engineers, that a vertical-faced sea-wall on the foreshore scours away the beach by the recoil of the waves from the face. Such walls are, therefore, when used for sea defence, practically always built with a curved or stepped face. The latter is, in my opinion, the best form.

Relative to groynes. There are sound methods of extending beyond low-water mark other than those described in the paper. I may say that having tried sheet piling I found it most unsuitable. My firm have extended groyne successfully beyond low-water mark by using weighted panels sliding on iron piles, the panels being composed of timber and reinforced concrete. The type of groyne we now use is made entirely of ferro-concrete and can be extended beyond low water. It is a development of the "Case" system and does not decay like timber, and unlike concrete is capable of easy adjustment to the varying level of the shore. I mention this as it has not been referred to in the paper and in order to bring the matter up-to-date. Ferro-concrete is, in my opinion, the material of the future for groynes. I explained its application very fully in my evidence before the Royal Commission.

Turning now to Mr. Carey's remark that a three or four knot current is capable of moving "normal sea sand"—a three knot current has been shown to be capable of moving flints of ten cubic inches, and a four knot current would certainly roll along boulders four to six inches in diameter. As a matter of actual experiment a current of 0·6 of a knot will move sea sand.

The references to the "Case" groynes are, I think, somewhat misleading. Mr. Case was the pioneer of the *low* system of groyning; the method of fixing the piles in the foreshore was not always that described, but was varied to suit the shore. The essential points in the system were the construction of long, low, adjustable groynes. I am very pleased to note that the author has paid Mr. Case the compliment of adopting his system, only the minor detail of the method of fixing the piles being changed. As to the necessity for extending groynes to high-water mark, this was early recognised, and very many "Case" groynes were so extended. Mr. Case certainly revolutionised the methods of sea-defence engineers in this country.

There are many points in the paper with which I am in entire agreement, expressing as they do some of the well-known rules relating to sea-defences. The subject is an extremely important one, and the necessity for soundness of theory, and an unbiassed statement of facts, as far as known, must be my excuse if I have appeared hypercritical.

JOHN S. OWENS,
M.D., A.M.Inst.C.E., F.R.G.S.,
Member of the Research Department of the Royal Geographical Society.

Mr. CAREY writes:—With regard to Mr. Rowland Halls' remarks on armoured concrete groynes for Roedean, I note that these are about to be erected. They have not yet been actually built. The application of concrete to varying purposes has been so habitual with me that I have heard it asserted that I should be seen someday carrying a concrete umbrella. Armoured concrete is a material I am now largely adopting. Mr. Halls does not state how the concrete planks or panels he proposes to use are to be secured to the piles. The piles will have to be driven on a rough beach and in a tideway.

I have read Dr. Owens' notes with interest. In one or two particulars he has rather missed the points I was trying to make. I do not, of course, dispute the evidence of the Continental platform, but I gather Mr. Reid's contention to be that, at an approximately defined date (about 4,000 years ago), the relative levels of land and sea resulted in a general coast line, apparently about 60 feet lower than exists to-day. I think we want much stronger proof than has yet been forthcoming, before this can be asserted with confidence.

The assumption of a rise of sea level on an enormous scale (such as 600 feet), to cover the Continental shelf, appears to me highly problematical. A local lowering of land level would be far more likely, and either assumption would fit the facts.

With regard to the travel of a pebble along a beach, the explanation offered in my paper was in general terms, and is, I believe, correct. The action of gravity will, of course, modify the oblique motion, causing a slight curvature in the path of the pebble, as it is forced up the beach. The return of the pebble, however, is certainly at right-angles to the foreshore, as the lateral forces acting on it have ceased to exist, and the pebble has momentarily come to rest, at its highest altitude.

If Dr. Owens refers again to my paper, he will see that I laid particular stress on the effects of underscour on a sea-wall and the resolution of wave impact, on a vertical faced wall, into vertical components, upwards and downwards. Instead of trusting to an ornate and expensive section, I bring shingle and reinforce the cheapest possible form of wall, with the defence Nature provides.

Laboratory experiments on the velocity of a scouring current are apt to be misleading. When smooth sand lies at some considerable depth, a current of high velocity is required to create scour. The dislodging of sand particles from a sea-bed depends more on local agitation than on the action of horizontal stream lines. The velocity of current capable of moving boulders of 4 to 6 inches diameter would depend on what the boulders rested upon. Dr. Owens does not say how sheet piling of groynes, below low water, fails. I have used it with complete success.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday Evenings, at 8 o'clock:—

MAY 15.—"Trypanosomiasis or Sleeping Sickness." By HERBERT W. G. MACLEOD, M.D., B.Sc.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

MAY 30.—"Irrigation Colonies in India." By LAURENCE ROBERTSON, I.C.S., Under Secretary to the Government of India, Revenue Department. CHARLES EDWARD HENRY HOBHOUSE, M.P., Under Secretary of State for India, will preside.

APPLIED ART SECTION.

Tuesday evenings, at 8 o'clock:—

MAY 28.—"Sheffield Plate and Electro-plate." By SHERARD COWPER-COLES.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 13...Surveyors, 12, Great George-street, S.W., 8 p.m. Mr. Maurice L. Gwyer, "The Prevention of Corruption Act, 1906."

Geographical, University of London, Burlington-gardens, W., 8½ p.m. Lieut. Boyd Alexander, "An Expedition from the Niger to the Nile."

Medical, 11, Chandos-street, W., 8 p.m. General Meeting.

Victoria Institute, 8, Adelphi-terrace, W.C., 4½ p.m. Dr. Ernest W. G. Masterman, "Recent Discoveries in Palestine and Syria."

TUESDAY, MAY 14...Asiatic, 22, Albemarle-street, W., 3 p.m. Annual Meeting.

Royal Institution, Albemarle-street, W., 3 p.m. Mr. D. S. MacColl, "Alfred Stevens (the English Sculptor and Painter). (Lecture I.)

Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m.

Statistical, The Surveyor's Institution, 12, Great George-street, Westminster, S.W., 5 p.m. Lord Eversley, "The Decline in Number of Agricultural Labourers in Great Britain."

Photographic, 66, Russell-square, W.C., 8 p.m. Mr. E. T. Holding, "The Camera at Home."

Anthropological, 3, Hanover-square, W., 8½ p.m.

Colonial Institute, Whitehall Rooms, Whitehall-place, S.W., 8 p.m. Mr. W. L. Griffiths, "Some Phases of Canada's Development."

Horticultural, Vincent-square, Westminster, S.W., 3 p.m. Mr. H. Stevens, "Photographing of Flowers and Animals."

WEDNESDAY, MAY 15..SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Dr. H. W. G. Macleod, "Trypanosomiasis or Sleeping Sickness."

Meteorological, 70, Victoria-street, S.W., 4½ p.m. 1. Dr. Hugh Robert Mill, "The Standard Rain Gauge, with Notes on other Forms." 2. Mr. J. W. Lovibond, "A Method and Apparatus for Measuring Fog Densities." 3. Colonel J. E. Capper, "Note on a Balloon Struck by Lightning April 11th, 1907." 4. Messrs. J. Nevin and A. S. Herschel, "Account of a Remarkable Excavation made by Lightning in Peat-earth on August 2nd or 3rd, 1906."

Geological, Burlington-house, W., 8 p.m.

Microscopical, 20, Hanover-square, W., 8 p.m. 1. Prof Alfred W. Porter and Mr. P. F. Everitt, "Diffraction Rings due to a Circular Aperture." 2. Mr. E. M. Nelson, "An Improved Vertical Illuminator." 3. Exhibition of Pond Life.

British Archæological Association, 32, Sackville-street, W., 8 p.m.

Pharmaceutical, 17, Bloomsbury-square, W.C., 8 p.m. Annual Meeting.

THURSDAY, MAY 16....Antiquaries, Burlington-house, W., 8½ p.m.

Chemical, Burlington-house, W., 8½ p.m. 1. Messrs. W. Barlow and W. J. Pope, "The Relation between the Crystalline Form and the Chemical Constitution of Simple Inorganic Substances." 2. Mr. J. Hübner, "Experimental Investigation into the Process of Dyeing." 3. Messrs. W. H. Perkin, jun. and R. Robinson, "Some Derivatives of P-pyranol Allied to Certain Derivatives of Brazilein and Haematein." 4. Mr. G. D. Lander, "Mixed Semi-Ortho Oxalic Compounds." 5. Mr. J. B. Cohen, "The Mechanism of Bromination of Acylamino-Compounds." (Preliminary notice)

Journal of the Society of Arts.

No. 2,843. VOL. LV.

FRIDAY, MAY 17, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

CONVERSAZIONE.

The Society's Conversazione will be held, by arrangement with the Council of the Royal Botanic Society, in the gardens of that Society, Inner Circle, Regent's-park, on Tuesday evening, July 9th, from 9 to 12 p.m.

The central portion of the gardens only will be used. The Conservatory and the Club-house will be open.

The reception, by Sir Steuart Colvin Bayley, K.C.S.I., C.I.E., Chairman, and the other members of the Council, will be held at the entrance to the Conservatory, near the Broad-walk, from 9 to 10 p.m.

Each member is entitled to a card for himself (which will not be transferable) and a card for a lady. In addition to this, a limited number of tickets will be sold to members of the Society, or to persons introduced by a member, at the price of 5s. each, if purchased before the day of the conversazione. On that date the price will be raised to 7s. 6d.

Members can purchase these additional tickets by personal application, or by letter addressed to the Secretary at the offices of the Society, John-street, Adelphi, W.C. In all cases of application by letter a remittance must be enclosed. Each ticket will admit one person, either lady or gentleman, and must be signed by the member applying for it.

Tickets will only be supplied to non-members of the Society on presentation of a letter of introduction from a member.

A programme of the arrangements for the evening will be published in due course.

STOCK PRIZE.

FOR THE DECORATION OF PART OF THE INTERIOR OF A BUILDING.

The Council of the Society of Arts are prepared to offer, under the terms of the Stock Trust, a Gold Medal, or a Prize of £20, for competition amongst the students of the Schools of Art of the United Kingdom, at the Annual Competition to be held in 1908.

The Prize is offered for the best original designs for an Architectural Decoration, to be carried out in painting, stucco, carving, mosaic, or any other process.

This Architectural Decoration is to be for the side of a room or a hall, a ceiling, the apse or side of the chancel of a church, or any suitable part of the interior of a building.

The designs must be on imperial sheets. Each set must consist at least of a coloured drawing to scale of the whole design of decoration, and two coloured drawings of details on separate imperial sheets. Mere patterns or sketches of details, without the mouldings or borders necessary to make up a complete decorative scheme, will not be taken into consideration. The designs must have been made between 1st April, 1907, and 31st March, 1908.

The recipient of a prize awarded under this trust in 1893 or 1897 cannot compete again.

The designs are to be submitted, with other school work, in the usual manner, to the Board of Education, South Kensington, in April, 1908. Each of the imperial sheets, forming a set of competing designs, must be marked, "In competition for the Stock Prize," in addition to being labelled or staged according to the Regulations of the Board of Education.

PROCEEDINGS OF THE SOCIETY.

TWENTY-FIRST ORDINARY MEETING.

Wednesday, May 15, 1907; SIR WILLIAM HOOD TREACHER, K.C.M.G., Member of the Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Desmond, Veterinary-Surgeon J., Adelaide, South Australia.

Graham, Walter Armstrong, The Residency, Kelantan, Siamese Malay States.
Hepburn, Arthur E., 956, Nicola-street, Vancouver, British Columbia, Canada.
Loveless, Thomas Henry, 76, Harley-street, W.
Osment, Harry Shorthose, care of British Vice-Consul, Lima, Peru, South America.
Schlict, Paul, St. James's-court, Buckingham-gate, S.W.
Underwood, Edward, Thorndon, Baldock-road, Letchworth, Herts.

The following candidates were balloted for and duly elected members of the Society:—

Coelho, Sertorio, M.A., Rua do Conselheiro No. 7, Nova Goa, Portuguese India.
Ford, James Francis, 17, Pembridge-square, W.
Gossain, Hem Chandra, Tezpur, Assam, India.
May, Theodore Martin, Assoc Am.Soc.C.E., Rooms 1745-1749, 42, Broadway, New York City, U.S.A.

The CHAIRMAN, in introducing the reader of the paper, said that Dr. Macleod, in the early part of his career, served for a few years in India in the Indian Medical Service, since when for many years he had been lecturing on and teaching preventive medicine and bacteriology, and had also instructed medical men as demonstrator and as assistant lecturer at King's College and at the London Hospital.

The paper read was—

TRYPANOSOMIASIS OR SLEEPING SICKNESS.

By H. W. G. MACLEOD, B.Sc., M.D., D.P.H. (late H.M's I.M S.).

The earliest record of this disease, which has of late attracted so much attention, was made by Winterbottom in 1803. He observed it among natives of Africa in the neighbourhood of Sierra Leone. It was noticed also at a later period in the West Indies, where it occurred among slaves imported from Africa. They were liable to be attacked some time after landing, and even after several years of apparently good health. The significant point is that all those who had the disease had come from Africa; and we now know they contracted the disease there.

Sleeping sickness is endemic in Equatorial Africa. At first it was noticed in places on or near the East Coast, and (tracing it along this coast-line from north to south) it is known that the following localities are in the zone of infection:—The Senegal River, Senegambia, Sierra Leone, Liberia, the Ivory and Gold Coasts, Upper Guinea, Biafra, the Camaroon country, the Congo, and Loanda in Portuguese West Africa.

The disease is also to be met with far inland, in Central Africa. At the mouth of the Congo it is not very prevalent, but it is very fatal all along both banks and particularly on the south side of that river. At Leopoldville, Stanley Pool, and Lukolela areas have been devastated by Sleeping Sickness. In 1900 Cook found it was present in Uganda, and since then it has extended to the shores of the Victoria Nyanza and Albert Nyanza, and also to the east and south. It is probable that Emin Pasha's Soudanese (who came from the Congo, numbering 10,000, and settled in Busoga) introduced the disease into Uganda. British East Africa, east of Kisumu, has escaped; and up to the present German East Africa has, I believe, not been infected. The disease is endemic in certain regions along the course of rivers and their affluents; the Senegal, Niger, Congo, and the Nile are specially affected; and, strange to say, villages close to one another remain quite free from infection, although in their immediate neighbourhood the death-rate from Sleeping Sickness is appalling. The outbreaks occur suddenly, and, although several members of a family may be attacked, it is usually found that, though exposed to similar conditions, all do not suffer, but only single individuals succumb. Old people do not as a rule contract the disease, those most susceptible are young children and young adults, between the ages of five and nineteen years. In some places, Uganda for example, people of all ages are liable to infection. All races are equally open to attack. Among those investigating the causes of Trypanosomiasis was Lieutenant Tulloch, of the Royal Medical Staff Corps, who was infected in Africa, and came back to die. A Frenchman died in Paris from the same cause; and both at the London Hospital and at Charing Cross Hospital, Europeans from infected districts have been under treatment. The mortality, when once the later stage of the disease is reached, is 100 per cent. In other words, recovery is unknown, although it is possible that the germs of infection may die off in the blood before they have given rise to the symptoms of Sleeping Sickness.

The spread of civilisation, the exploration of the country, and the opening-up of trade have brought before the various Governments concerned in African affairs the importance of investigating the causes of a deadly disease which has been rapidly spreading during

recent years. Portugal, Belgium, France, and Germany have all sent investigators, and have spent large sums of money for the discovery of its cause and for preventing its dissemination, if possible. It is known that in the valley of the Congo from 400,000 to 600,000 deaths have occurred from this disease during the past 10 years; and in Uganda alone the mortality has reached 40,000 to 50,000. In 1902 the British Foreign Office, in conjunction with the Royal Society, sent out a special Commission to Uganda to investigate the cause of the malady and to report accordingly. Colonel David Bruce, of the Army Medical Corps, a graduate of the University of Edinburgh, was the senior member of the Staff, the others were Captain Greig, I.M.S., and Dr. Nabarro. The work was commenced at Entebbe.

Shortly after the arrival of the Commission, Dr. Castellani, not a Member, was the first to discover a parasite known as a trypanosome in the spinal fluid of five persons infected with Sleeping Sickness; and also in the blood of one of these cases. He suggested that a micro-organism classed as a diplococcus was the cause of the disease, and not the trypanosome. The statement has also been made that he "put forward the view that the trypanosome was the essential cause, and the diplococcus a secondary infection of great importance in the disease." Further researches showed that the trypanosome was to be found in all cases of Sleeping Sickness and also in the blood, though not in the spinal-fluid, of a certain number of persons residing within the infected area in Uganda. These individuals, however, showed no symptoms of the disease.

Colonel Bruce had previously discovered the cause of the tsetse-fly disease among horses in South Africa, and known as *Nagana*, to be a trypanosome in the blood of the infected animals conveyed by *Glossina morsitans*; and he traced the source of infection in Sleeping Sickness to the fly known as the *Glossina palpalis*, a species of the tsetse-fly. To quote his words, "We found the distribution of the disease to be most peculiar. It was confined to a narrow strip of land running along the shore of the lake and to the many islands which dot the northern shore of the lake. It was thought that this peculiar distribution must depend upon some peculiar factor and that factor we found in the *Glossina palpalis*." The distribution of this fly and the distribution of Sleeping Sickness were found to be identical. "Where none of these flies existed there was no Sleeping Sickness." Doctors Ford and Dutton discovered a trypanosome in the blood of a European suffering from fever on the Gambia, and they suggested this was the first stage of the disease. It is now accepted as a fact that the *Trypanosoma Gambiense* and the trypanosome found in Sleeping Sickness are one and the same parasite.

The *Glossina*, or tsetse-fly, is confined to Africa, and inhabits the tropical and sub-tropical regions. The northern boundary of the fly-zone runs from Cape Verde across the middle of Lake Chad to the Nile. Its southern limit extends from the mouth of the Cunene River, at Cape Frio, to the southern boundary of Angola and to the north-eastern end of St. Lucia Lake, in Zululand. These boundaries correspond very closely to those within which trypanosomiasis is known to prevail.

The flies are brownish or greyish-brown in colour, and all of them have a prominent proboscis which is distinctive. The *Glossina palpalis* is the darkest of all the species. The Boers first came across the tsetse between 1835 and 1837, when they made their well-known trek. Later it was found near the Limpopo river by British settlers. Its name is probably derived from the peculiar buzzing sound it makes when flying, or when commencing to suck blood. Mr. Austen, who has made a special study of these insects, and whose book on the *Glossina* is a standard work on the subject, describes it as having a buff-yellow median stripe on the abdomen, and pale "femora," or thighs. The hinder-half of the body is of a paler colour, and has sharply-defined dark-brown bands. When in a resting position the tsetse can be distinguished from all other diptera (or two-winged flies) by its brownish wings lying folded flat, one over the other, down the back. The wings overlap like the blades of a pair of scissors do when closed. The proboscis, sheathed in palpi, projects horizontally in front of the head. The length of the insect, from the tip of the proboscis to the end of the closed wings is about half-an-inch. It is a peculiarity of the *Glossinæ* that they do not lay eggs, but "extrude a yellow coloured larva," nearly as large as the abdomen of the parent fly. At the posterior end of the larva are two projections; the body is divided into ten segments, and is full-grown when extruded. The insect crawls away at once for cover, and after a few hours changes colour and forms a hard and black pupa. Here, also, the tumid

lips of the last segment are well seen, and they are covered with granules. The notch between the projections is larger than in the larva. In about six weeks time the fly is fully developed.

The habits of *Glossina palpalis* differ to some extent from those of *Glossina morsitans*. Both are blood-suckers, and resemble each other very closely in appearance, but the former feeds largely on human blood, and the latter appears to depend for its existence upon animals—on big game in particular—and when these are exterminated the tsetse fly may die out. At any rate it is not found where they are absent.

Unlike the mosquito, the *Glossinæ* of both sexes suck blood. When it scents its prey the tsetse makes its peculiar buzzing noise and flies straight to the most accessible part, by preference, to the leg or foot, if exposed. The site of puncture is very painful at once, but it is stated no irritation follows later. A hard nodule may remain for a few days unaccompanied by any marked swelling or discolouration (Christy). In about half-a-minute to two minutes the fly is filled with blood, and after feeding flies away slowly and hides itself, digesting its meal while resting.

As already mentioned, the tsetse inhabits belts or patches of forest, and is seldom far from water of some kind. Bush, banana plantations, and the margins of rivers, lakes, and watercourses form its favourite haunt. At fords and bridges, and where human beings are constantly to be met with, the *Glossina palpalis* abounds; also within the interior of forests, though in far less numbers. It does not bite, as a rule, early in the morning; more often during the later period of the day, and even late in the evening. During wet and dull weather, fewer flies are encountered, and at certain times of the year these are either quiescent or absent. Further observations are needed on this point, and it is very probable that their habits vary with local conditions.

For the spread of Sleeping Sickness, it is necessary:

1. That individuals have trypanosomes in their blood.

2. That the particular species of tsetse-fly bite them.

3. That the fly within forty-eight hours, or at most within three days, inoculate a non-infected person.

So far as is known at present, *Glossina palpalis* is not able to, or does not, retain its infective quality beyond that period of time.

Evidence is accumulating that not only this fly, but others of the same species, may carry infection to man and also to animals. It has been ascertained by experiment that monkeys, guinea-pigs, rabbits, rats, and other animals can be inoculated with human trypanosomes taken from cases of Sleeping Sickness, the infective material being present in the blood. Experiments with such biting-flies as *Stomoxys* and *Tabanus* have not been successful in animals infected with Nagana, but these flies can spread the trypanosome of Surra in India.

Let us now turn our attention to this mysterious organism, the trypanosome. It was first found in the blood of a patient suffering from fever in the River Gambia Colony by Forde in 1901. Dutton, who was working with him (and who has since died in Africa when engaged in research-work), recognised the parasite, and named it the *Trypanosoma Gambiense*. It is formed of protoplasm, is single-celled, and has an irregular shape. It is pointed at each end, possesses a nucleus, a smaller dot or nucleolus, and a peculiar wavy line, known as the "undulating membrane," which commences in the nucleolus at one extremity and terminates at the other anterior end in a fine thread or "flagellum." This acts as a propelling organ, and by lashing movements the trypanosome swims about in the blood-stream—a worm-like organism wriggling actively among the blood-dics. Differences of sex have not been discovered in these bodies. They reproduce themselves by splitting up along their length—by "longitudinal division" as it is termed. Recent observers suggest the theory that the two nuclei are connected by a band which can be seen to grow out from the small, and to extend through the body of the organism, towards the larger nucleus and even beyond it. This structure is thicker than and quite distinct from the "undulating membrane," and when it is complete small trypanosomes are formed, and the life-cycle of the parasite recommences. At present the evidence is still in favour of the view that all the stages of development of the trypanosome of Sleeping Sickness are completed within the body of its human host and not in the alimentary canal of *Glossina*—differing thus from what takes place in the mosquito, which is the carrier of the germ of Malaria. We know that the parasite is found in flies caught near huts containing

persons suffering from the disease, and it is believed by some that in the alimentary canal of the fly the organism mutiplies and undergoes some change. Yet preparations made from the blood taken from the stomach of the tsetse and examined microscopically have not shown that alterations or stages occur.

The question may suggest itself, "Whence comes the original trypanosome?" That we cannot answer, as it amounts to explaining an *initium vitæ* which Science cannot at present elucidate. The parasite passes from the fly directly into the blood-stream of its victim. Later it invades the lymphatic glands, and last of all passes into the spinal fluid.

Turning next to the symptoms of the disease —which I shall only touch lightly on—it has not been possible to tell how long a person may remain infected without showing any signs of the malady. This hidden or "latent" stage may extend over a year or more; or the signs of illness may be so indefinite, or may come on so gradually that suspicion is not easily aroused. The first symptom that attracts notice is an enlargement of the glands in the neck wihout obvious cause. Other glands also became infected. From these glands the parasite may be obtained, and then all doubt as to the nature of the affection is removed. Later on nervous symptoms supervene—great lassitude, dullness, lethargy, or a stolid expression or puffy state of the face; and with these great emaciation occurs. It is important to note that in cases which ended fatally, sleep symptoms were occasionally not in evidence, and in others they were slight and unimportant. The nomenclature commonly adopted may, therefore, be misleading; this heavy sleep is symptomatic in a comparatively small number of cases, and in every instance, when present, it indicates the terminal stage of the disease.

Treatment by drugs has, I regret to say, not been satisfactory. Recently Atoxyl has been administered, and a few patients have apparently benefited under its use; it is still under trial. Strychnine and arsenic have also been given, and are not curative.

Electricity has been been brought into use, and Ross, of the Liverpool Tropical School of Medicine, states it has no effect on trypanosomes. In Paris the Benzidine colour treatment (on animals) has not been satisfactory. More recent investigations on monkeys have given better results, but it is quite uncertain if these drugs will cure the disease in man.

Turning, lastly, to preventive medicine, what can be done to check a fatal disease, which is spreading rapidly in Africa, and which may, by extending along trade routes, invade South Africa, Egypt, the Soudan, and India? Is it possible to exterminate the tsetse fly? Administrative measures must be taken to control the movements of infected people. It is difficult to discover the disease at an early stage, and, consequently, a dangerous class exists which forms a focus of infection wherever the *Glossina* is found. It follows, therefore, that a special staff of experts is needed to detect early cases. The geographical distribution of the tsetse-fly in Africa is not accurately known, and there may be other species which convey infection.

Posts of inspection should be instituted along trade routes, so that all suspicious persons can be examined by medical experts. Infected individuals should be removed from uninfected districts, and every employer of labour ought to be compelled to have his men examined and treated.

That the disease may invade Egypt and India is only too possible. In South America a fly disease infecting horses is known to exist, and in India Evans first discovered a trypanosome, in 1880, which causes a disease known as "Surra" in horses and cattle, and is due to the bite of a blood-sucking fly. A similar parasite has been found in French Indo-China.

Foreign Governments have taken up the matter. The King of the Belgians has interested himself, and has instituted a prize of £8,000 for anyone who discovers a cure for the disease. He has, in conjunction with the Congo Free State, provided an institute for research, with a suitable staff located in the endemic area. The German Government has voted £6,000 for an expedition under the celebrated Professor Koch; the French Geographical Society has organised an expedition, and has set aside £8,000 for estimated expenses during a period of 18 months.

The British Government has not taken very active steps in the matter. Questions have been asked in Parliament, and it was stated in November last that two medical officers were to be sent to British Central Africa to study local conditions and to suggest preventive measures, and they were expected to arrive there by January of this year. It has been suggested that game-preserves in Africa might spread infection; but the Commissioner of the British Central African Protectorate and of North-East

Rhodesia reported that no such evidence was forthcoming. The Secretary of State for the Colonies stated, "if it could be shown that the removal or the contraction of the reserve would increase the health and security of the neighbourhood, instructions would be given accordingly."

A Commission to investigate the occurence of Sleeping Sickness in the Soudan has been appointed. Liverpool has taken a leading part in investigating the disease, and the Chamber of Commerce there passed a resolution last year to call the attention of the Secretary of State for the Colonies to the importance of active measures being taken. On the 4th of this month two members of a Commission from the Medical School left for Central Africa to prosecute further researches.

The Germans are closely watching the Uganda border to prevent the extension of the disease into their possesions. Epidemics are not abating but on the contrary are invading new districts. It is of the greatest importance for the British Government to take the lead as it has the largest interests at stake; and it is a dangerous policy to act on the motto *Festina lente !*

May I ask if this Society, with its well-known scientific status and its influential Council, can take action in the matter?

DISCUSSION.

The CHAIRMAN, in opening the discussion, said that being only a layman it was not competent for him to offer any criticisms on a paper which had been carefully thought out by an expert; but he desired to say he was cordially in accord with the concluding paragraph of the paper, in which Dr. Macleod stated that, in view of the action being taken by other nations, it was of the greatest importance that the British Government should take the lead, as it had the largest interests at stake. He had served in the tropics for 30 years, in Labuan, Borneo, and the Federated States of the Malay Peninsula, and he had frequently seen scattered over those countries cemeteries in which were buried a comparatively large number of white men, such as soldiers, sailors, civilians, planters, and merchants. The graves of many Chinese and Tamils were also to be seen, they being the races from which the labour forces of those colonies were recruited; and the larger proportion of those deaths was undoubtedly due to malarial fever. Apart from the sad loss of life, it was easy to imagine what a wastage there had been of labour and money, and what a delay had occurred in the development of those countries owing to the mortality which had taken place, much of which could have been minimised if the British Government had earlier taken up the study of tropical diseases, and endeavoured to counteract their ravages. It was not until Mr. Joseph Chamberlain took charge of the Colonial Office that anything was really done in that direction, and since then the London and Liverpool Schools of Tropical Medicine had been originated, at which doctors went through a course of training which fitted them to cope with tropical diseases. As a concrete instance of the value of his training, he might mention that, not very long ago, he opened a new harbour, known as Port Swettenham, on the west coast of the Malay Peninsula. Soon after it was opened, malarial fever, of a most virulent nature, attacked the inhabitants of the district, the coolies and the crews of the ships, and he was asked to close the Port, at any rate for a time. Instead of doing so, he called in the Government doctors, who had been trained at the London School of Tropical Medicine, and the Government engineers; a scheme of drainage and of other remedial measures was carried out, and in a few months the place was perfectly healthy; indeed it was now almost regarded as one of the healthiest seaside resorts on the coast, and vessels of the P. and O. and other companies were making use of it.

Sir JOHN CAMERON LAMB said that as Dr. Winterbottom was a fellow townsman of his he had been exceedingly interested in the author's statement that Dr. Winterbottom was one of the first men who described sleeping sickness. Only a few weeks ago he received from another old friend, Dr. James Gray Glover, a confirmation of that fact, and the further statement that Dr. Winterbottom's paper, though written more than 100 years ago, was still regarded as a treatise of considerable value. He had personally felt very depressed while listening to the paper, because everything seemed to be so hopeless; but it might cheer the meeting, as it cheered himself, to know that Dr. Winterbottom, although he gave so much attention to such a hopeless subject, was one of the most cheerful persons who ever lived. It was encouraging to all concerned that a man who was so deeply concerned in the study of the subject should keep up his spirits, and he hoped they would all do so in spite of the very depressing but nevertheless most interesting statements of Dr. Macleod.

On the motion of the CHAIRMAN, a very hearty vote of thanks was accorded to Dr. Macleod for his interesting paper.

Dr. MACLEOD, in reply, cordially thanked the audience for the kind way in which his paper had been received. He had endeavoured to keep outside professional grounds and make it as popular and simple as possible. If he had failed to do so he regretted it, if he had succeeded in what he had done his pleasure was great.

THE COMMERCE OF THE BRITISH EMPIRE IN 1905.*

This valuable return, now appearing for the third year in succession, gives a general review of such matters as area, population, export and import trade and its distribution, shipping statistics, and production of certain staple commodities. In these notes a few of the more striking figures of a year of general expansion and unequalled activity will be referred to.

Total Trade of the British Empire.—The total foreign and inter-imperial trade of the Empire in 1905 reached the total value of £1,366,708,000, an increase of £62,000,000 over 1904, and of £354,000,000 since 1897. Of the sum total, 74·1 per cent., or £1,012,141,000, represents the external foreign trade of the Empire with foreign countries, of which the exports amount to £448,688,000, and the imports to £563,453,000, and 25·9 per cent., or £354,567,000, represents the inter-imperial trade, comprising £161,900,000 of imports into the United Kingdom from British Colonies and possessions, and £135,524 000 of exports from the United Kingdom to the rest of the Empire, together with an intercolonial trade reckoned at £57,143,000, being the value of goods imported into the colonies from other colonies.

As regards the total volume of trade between the Empire and specific foreign countries, first place is taken by the United States of America, to which the exports were valued at £83,631,000, and from which the imports were valued at £173,687,000. The exports to Germany were £61,613,000, and the imports from Germany were £48,608,000. Other leading countries to which exports were sent were—France, £51,433,000; Belgium, £23,237,000; Russia, £20,015,000; Holland, £16,731,000; China, £20,683,000; Japan, £18,467,000; and the Argentine Republic, £16,887,000. The imports from these countries were—France, £57,917,000; Belgium, £33,307,000; Russia, £35,268,000; Holland, £37,352,000; China, £4,425,000; Japan, £4,336,000, and the Argentine Republic, £26,442,000.

Staple Articles Imported from Foreign Countries.—Dealing only with specific raw materials and omitting food-stuffs, the imports of raw cotton into the Empire amounted to £52,299,000, of which £50,989,093 was imported by the United Kingdom at £1,148,268 by Canada. Raw wool was valued at £5,769,000, of which £5,285,653 was for the United Kingdom. As regards iron ore, the United Kingdom imported £5,453,474, a small quantity imported by Canada not being separately distinguished. The timber imports amounted to £22,065,000, of which the United Kingdom took £18,000,845.

Exports of Staple Articles to Foreign Conntries.—Confining our notes again to specific raw materials, the most important exports from the Empire to foreign countries amount as follows:—Coal, £25,380,000 (mainly from the United Kingdom); raw cotton, £19,376,000 (mainly from British India, £13,139,079), the sum of £6,132,927 representing re-exports from the United Kingdom; raw wool, £26,867,000, (£14,912,341 from the United Kingdom, and £11,045,631 from the Australian Commonwealth); and timber £5,428,000 (of which £4,110,023 was from Canada).

Raw Materials and Manufactured Articles Imported into the United Kingdom from British Colonies and Possessions.—Copper ore, £295,534; copper regulus and precipitate, £782,657; unwrought copper, £850,852; raw cotton, £1,202,563; raw jute, £5,669,239, raw wool, £20,600,774; tin, £5,425,040.

Manufactured Articles Exported from the United Kingdom to British Colonies and Possessions.—In view of the many headings under which these returns are made only a few can be recited, these figures being compiled from the annual trade statements. For instance, out of cotton manufactures having a total value of £37,697,702, British India received £24,811,875, the Australian Commonwealth £3,315,325, Canada £1,605,678, the Straits Settlements £1,572,441, and Hong Kong £1,412,490. Woollen and worsted manufactures totalled £8,502,602, the chief purchasers being British India, £936,252; the Australian Commonwealth, £2,181,023, and Canada £2,713,108. Machinery and mill-work totalled £7,006,888, India purchasing £3,871,471; the Australian Commonwealth £813,432, Cape Colony £582,748, Natal £570,721, and New Zealand £327,940.

Shipping Statistics.—The bulk of the tonnage of vessels built within the Empire is launched within the United Kingdom, where, exclusive of war vessels, 1,037,838 tons was launched in 1905. Other totals are—British India, 7,422; New South Wales, 1,273; New Zealand, 1,395; Canada, 21,865; Newfoundland, 3,121; Straits Settlements, 9,189; Hong Kong, 3,695; and West India Islands, 388. The total tonnage of sailing and steam vessels on the register for the Empire as a whole was 12,332,404, of which 10,735,582 tons was registered as belonging to the United Kingdom, 85,777 as belonging to British India, 352,455 to the Australian Commonwealth, 668,314 to Canada, 117,583 to New Zealand, 129,617 to Newfoundland, and 48,769 to the West India Islands.

Other interesting tables show the volume of shipping entered and cleared between the United Kingdom and each colony, and summarised tables show the small extent to which foreign-owned vessels participate in this trade.

Total Values and Quantities of Staple Articles Produced within the Empire.—In regard to all industries connected with mining save that of coal, the total value produced in 1905 exceeds that recorded for any preceding year. Even in regard to coal, the volume produced exceeds all other records in volume by reaching 265,356,000 tons, of a value of

* Compiled from the Statistical Abstract for British Empire 1891-1905 (Cd. 3328); published by Wyman and Sons, Ltd., Fetter-lane, E.C. Price 1s.

£91,700,000; which may be contrasted with 1900, when the volume was 244,378,000 tons, and the value, £128,800,000. The iron ore produced amounted to 15,600,000 tons, and the pig iron produced (partially, of course, from imported ores) was 10,079,000 tons. The gold production reached 11,106,000 ounces of varying fineness, valued at £46,600,000. The value of the copper produced was £4,184,000, and of tin, £8,700,000.

Passing to statistics of agricultural production, variations in the total yearly production are naturally encountered. So far as can be enumerated the yield of wheat in 1905 was 535,600,000 bushels, a figure exceeded in 1903 by nearly 20,000,000 bushels, but 95,000,000 bushels in excess of 1904. The barley production amounted to 109,200,000 bushels, a figure slightly exceeded in 1902. The yield of oats in 1905 was 341,100,000 bushels, 1902 being the year of greatest production, when the total was 354,400,000 bushels. The total amount of tea amounted to 398,184,000 lbs., a figure more than double that returned in 1891. The coffee production is less satisfactory, very violent fluctuations occurring. The yield in 1905 was 41,494,000 lbs., with which may be contrasted the minimum yield of 28,901,000 lbs. for 1901, or 59,195,000 lbs. for 1891, which is the first year covered in this summary. Complete figures as to the production of raw sugar were only available in 1898; the yield reported for 1905 of 47,200,000 cwts. is the lowest in the period under review. The yield of rubber in 1905 was 9,253,000 lbs., a figure which may be contrasted with a yield of 3,900,000 lbs. in 1902, or 12,787,000 lbs. in 1896.

The total production of cotton amounted to 1,306,188,000 lbs., of which 1,299,600,000 lbs. was Indian grown. Other quantities included: British Central Africa, 2,377,760 lbs.; Lagos, 1,281,072 lbs.; Barbados, 344,232 lbs.; and Cyprus, 782,712 lbs.

Other tables deal with wool production, and also the number of live stock, coal, iron, and tea, beer, wine and grain consumed (in bulk and *per capita*), to which reference can be readily made by those interested in specific items not dealt with in this summary.

THE INDIAN MOTOR TRADE.

India is rapidly taking a leading place in the world's motor markets, and this country is worth the careful attention and thorough investigation of manufacturers who are seeking to enlarge their markets. The value of the trade is seen from the official statement that the motor cars, motor cycles, and cycles, imported during the last fiscal year amounted approximately to £42,000, of which one half was through the port of Bombay, the supply mart of Western India. Accessories, which are classed under different headings, add to this total, while fuel and lubricating oils have had largely increased sales since the use of motor cars has become popularized. One cause of the popularity of the motor in India is the number and the extent of good roads, some of them hundreds of miles in length. A perfect highway runs from Bombay to Delhi, 900 miles, over which the trials were made in 1904. From Peshawar, further north at the frontier of Afghanistan, a fine road extends all the way to Calcutta, a distance of 1,500 miles. These and similar roads are known as the grand trunks, and were built and maintained as military highways before the advent of the railways. They are kept in a perfect state of repair. Other highways equally good are spread throughout the country, and in some of the States ruled by the native princes, great attention is given to the roads. One enterprising prince, the Maharajah of Gwalior, has caused a motorists' road guide of his State to be published with maps, lists of rest-houses and other information. The high class and high-priced cars, which in any country must be considered as luxuries, have found their best customers among the native rulers, whose example has been followed by the rich Parsee merchants and financiers of Bombay, and in a modest degree by some of the officials of the Indian Government. According to a recent report by a Special Agent of the United States Government, the use of motors has gradually spread until they have ceased to be looked upon as luxuries, and are now regarded as necessaries by a growing number of people who are able to invest from £200 up to £1,000 in a motor vehicle. At first it was found necessary to employ European chauffeurs, and this is still done by the owners of the finest machines, but it is now possible to obtain competent native chauffeurs at very moderate wages. The touring car will probably continue, for some time to come, to offer a good field for exploitation, since it is especially favoured by Government officials for use by themselves and their subordinates in reaching districts not accessible by the railways, and it should be understood that there are still many parts of India without means of railway communication. This is especially true of several of the Native States, whose rulers have been very enterprising in providing means of transit. The number of touring cars to be seen in the warehouses and garages of Bombay is also noticeable. Motor 'buses, however, are yet to be introduced in the chief cities. The motor cyele has a fair sale, and the bicycle has not been relegated to the background, as in other countries. The large number of British troops maintained in India is one explanation of the continued use of the motor cycle and the bicycle, since they are especially adapted to military needs. The value of the imports of bicycles is about £100,000 annually. A disposition exists in official circles to encourage the use of motor transport wagons for goods, as the solution of one of the many problems with which the Government has to deal, in the economic affairs of the country. In many of the interior districts much loss results every year through the inability of the country people to get their produce to market. The official suggestion is, that motor wagons might be manufactured, which could transport the produce to the railway station and then to be transferred to the railway trucks and be carried as are ordinary goods from station to station. Kerosine is proposed as the

most suitable fuel for machines of this kind, since the handling of highly volatile spirits such as gasoline is relatively costly in a country of high temperature, which India is. The significance of this suggestion regarding a special kind of motor for the railway trucks, is its recognition that touring and passenger travel is not the only use to which the motors can be put. Motor boats are also seeking an Indian market. The Government has ordered from England a police-boat which is to be fitted with a 6-horse power paraffin motor, and is to have a speed of six miles an hour. The dimensions are to be eighteen feet length and five feet beam. Since this boat may prove the type of others that will meet the requirements of Indian waters, further details of the construction are given. The shape is rectangular, with curved-in ends and sloped-up floor at bow and stern. The paddle wheel propeller is fitted inboard and not beyond the stern, as is customary. The engine is provided with a reduction pulley, whence power is transmitted to the paddle wheel by a broad flat belt. No clutch or reverse gear is provided. Instead, a jockey pulley serves to regulate the tension on the belt, allowing it to slip when required, a lignum-vitæ block-brake being at the same time applied to the belt. The boat is provided with two rudders, is built throughout of teak, and is copper sheathed. A few orders are said to have been given recently for motor-boats from Europe, while a local industry has sprung up in Bombay for the manufacture of hulls, the engines and machinery to be imported. It is claimed that the high-sea freight on motor-boats will prevent the importation of the hulls. The effort is also made to increase the use of paraffin or alcohol for fuel in place of gasoline, since the safety will be greater by the use of a heavier and non-inflammable material.

The important trade, however, for the motor industry in India will always be on land, rather than on water, and some additional particulars, therefore, may be of interest regarding the type of machines in use, and which promise to command the most profitable market. The Indian motorist does not care for great horse-power in the engines. From sixteen to thirty horse-power is the range, with a decided preference for the lower figure. Much attention, however, is given to the coach, which is expected to be both substantial and luxurious. The coach finish of the American cars, for example, is criticised for its roughness, and this objection applies also to the upholstering. Red leather is not disliked, and it may be said that the buyers in India, especially the natives, want plenty of light colours. They are also particular in wanting attractive engine fittings. The American motor-car is also too high to suit the motorists in India. They are accustomed to the English and French cars, hung low from the axles, and object to the inconvenience of climbing in and out of the automobile. Cars made for "bumpy" roads are not needed on the perfect highways of India. Other considerations are of a technical nature, such as relate to the very hot Indian climate, and also to protection from the penetrating moisture of the monsoon or rainy season, for motoring is not entirely restricted to the dry season. Generally, it may be said, that increased horse-power is of the least importance, and that the growing market is for machines built on the French lines. The trade up to this time has been largely controlled from England. The importations into Bombay, during the last fiscal year, from Great Britain, were valued at a little more than £100,000, and from France, about £18,000; but many of the machines credited to England in the Customs returns, are manufactured in France. The colonial rights are held in Great Britain, and under this arrangement the cars are often invoiced and shipped direct from France. Complaint is made that the British manufacturers are not up-to-date, and the concerns holding colonial rights from some of the French manufacturers are likely to do an increasing business. Italy has lately come into the Indian market with its perfected machines, and though the importation last year amounted in value to only £6,500, the future promises to show marked gains. The customers for the Italian high class cars have been found among the wealthy natives. The imports into Bombay from the United States were only valued at £3,000, though several years ago this total was exceeded, and great efforts are now being made by American manufacturers to gain a greater share of the Indian market, and with this object in view an American company has now manufactured a somewhat heavy machine, of 30-horse power, which in some particulars seems to satisfy the requirements of Indian motorists. There are more than six hundred licensed motors in Bombay, and it is observed that the latest licenses granted are for the more substantial cars.

ALCOHOLIC CONSUMPTION AND REVENUE.

For the sixth year the Board of Trade has just issued its memorandum and statistical tables showing the production and consumption of wine, beer, and spirits in the British Empire, and in the principal foreign countries, and the revenue derived therefrom in recent years. In addition to the beverages so classed there are certain others of a more or less alcoholic character not dealt with in the tables. No figures, for example, are available with regard to the production or consumption of cider in the United Kingdom, and so with revenue. Only the revenue raised for national purposes is considered, revenue raised for local purposes, whether in the form of octrois, and so on, being, as far as possible, excluded.

The quantity of wine produced in the British Empire is only very small. Practically none is produced in the United Kingdom or anywhere in the Empire other than the Cape of Good Hope and the Commonwealth, and in the Commonwealth the production is practically stationary. Whilst in 1901 Australia produced more than twice as much wine as the Cape of

Good Hope, in 1904 the Cape production exceeded that of the Commonwealth. It will surprise many to find that, although France holds the first place as a wine producer, even in such years as 1900 and 1904, she imported considerably more than she exported, her imports being derived principally from Algeria and Spain, and consisting for the most part of strong common wines, used chiefly for fortifying wines of French origin. About one-half of the rapidly-increasing production of Algeria is, in fact, taken by France. The consumption of wine in the British Empire is, as might be expected, relatively small, and it has beeu falling considerably since 1899. In 1905 it amounted to only a little more than a quarter of a gallon (·27 gallons per head). On the other hand, the consumption seems to have increased considerably in several Continental countries. In the quinquennial period 1891-5, the consumption in France was 23·0 gallons. In 1900-5 in had risen to 30·8 gallons. Taking the same periods, consumption had increased in Italy from 20·6 to 25·1, and in Germany from 1·10 to 1·45.

Turning to beer, it will be seen that in the United Kingdom the consumption has steadily declined since 1899, when it was 32·6 gallons per head of population, to 27·7 in 1905. But even the last figures are higher than those for any other country included in the tables except Belgium, where the consumption for some years showed a strong tendency to increase, having risen from 39·2 gallons in 1891 to 48·8 in 1905. In Germany, the consumption per head has ranged from 23·2 gallons in 1891 to 27·5 in 1899, and 26·3 in 1905. These figures apply to the whole of Germany. In particular parts of the Empire the consumption is much larger, as for example in Bavaria, Wurtemberg, and Baden. In these countries the figures for 1905 were 34·5 gallons in Baden, 38·1 gallons in Wurtemberg, and 51·7 gallons in Bavaria, the consumption in the latter country per head of population being greater than in Belgium, or in any other country of the world. It is noticeable that, taking the years 1901 to 1905, there is decline in consumption not only in the United Kingdom but in Australia and New Zealand, the only British colony showing increase being Canada. So with foreign countries; in all the Continental countries, with the exception of Belgium, where during these years the consumption has been practically stationary at 48 gallons per head, consumption has been declining, but in the United States there has been an increase from 14·6 to 16·8.

During the fifteen years dealt with in the return, the consumption of spirits per head of population in the United Kingdom has followed nearly the same course as the consumption of beer, having been low (0·97 proof galls.) in 1894, from which point it increased yearly to 1 09 galls. in 1899, and to 1·11 galls. in 1900, and has since decreased each year to a total of 0·9 galls. in 1905. The consumption of spirits per head of population in this country is lower than in any of the Northern and Central countries of Europe except Norway and (for one or two years) Russia. In the United States the consumption per head of population was greater than in the United Kingdom in 1891-3, but less than in 1894-1900. In 1901-5 it was again greater, having increased, whereas the consumption per head in this country diminished. In nearly all the Australian States there has been slight decrease in consumption, but in Canada it has risen from 0·76 to 0·94. In most Continental States there is a slight decrease, and in Belgium a considerable one, from 1·89 to 1·10, but this is attributed to the increase in the excise duty, which rose in 1903 from 100 francs to 150 francs per hectolitre.

An interesting series of tables is given in the returu showing the large part played by the revenue derived from alcoholic beverages in Governmental finance. Nowhere do taxes on these beverages contribute so large a part of the total national revenue as in the United Kingdom and the United States, the proportion so attributed in both countries for the years 1901-5 amounting to no less than 28 per cent. of their respective revenues. Next comes Holland and the Dominion of Canada, which derive 18 per cent. of their revenue from these beverages. Russia, Sweden, and Belgium get 17 per cent., and France 15 per cent. The proportion falls exceptionally low in Italy, Spain, and Servia, in which countries only 2 per cent. or less of the revenue is derived from the taxation of alcoholic beverages. If the revenue from Customs and internal taxation is taken, it is interesting to know that whilst the amount raised by internal taxation of wine, beer, and spirits in this country is surpassed by both Russia and the United States, the Customs revenue derived therefrom far surpasses that of any other country, and is more than twice as great as that of the United States, which stands second in the list.

JAPANESE EXHIBITIONS.

The Japanese patent-office exhibition building at Dosan Machi, Kojimachi, Tokyo, was opened on February 1st, 1907. The building is new and covers about 6,120 square feet. The exhibits, numbering over 2,200, are for the most part articles invented or designed by the Japanese and are protected by either Japanese patent or registration. Among them are clothing, boxes and receptacles, dyed and woven goods, buttons, rings, fans, stationery, toys, agricultural tools and implements, furniture and chemical apparatus, and among the patented articles are found fire extinguishers, engines, pumps, agricultural tools and looms. The exhibition is a permanent one and will be open daily. In connection with the international exhibition to be held in Japan in the year 1912, the following revenue is, according to the American Consul-General at Yokohama, reported and estimated—from the municipality of Tokyo, £300,000; from the national treasury, £500,000, and revenue from the exhibition, £200,000. The area of the exhibition ground is estimated at about 10,800,000 square feet. The principal buildings to be erected by the Government are two scientific buildings, two in-

dustrial buildings, two machinery and electric buildings, transportation buildings, marine product building, zoological, fine arts, agricultural, mining, forestry, foodstuffs, aquarium, and horticultural buildings. In addition to the foregoing, three concert halls for the use of the public, and a post and telegraph office will be built. Both foreign and domestic exhibits are to be classified, and will be placed in the sections devoted to them. The exhibitors will be allowed to erect buildings for their exhibits within the exhibition ground at their own expense. The site of the exhibition has not yet been selected, but the Finance Department and the Tokyo municipal authorities are reported to have agreed to hold the exhibition within, or in the vicinity of Tokyo, and the Tokyo Municipal Council recently voted a contribution of £300,000. The exhibition will be formally opened on April 1st, 1912, and is to continue for seven months. At the instigation of the Chambers of Commerce of several of the larger cities of Japan, aided by the civil authorities of Dalny, a commercial exhibition was opened in that city on February 1st last. One building composed of eight rooms is being used for the exhibition. The Japanese Commercial Museum at Mukden has proved to be such a success that it is contemplated keeping it open much longer than was originally intended. The Government and people of Japan are thoroughly imbued with the importance of exhibitions for the display of their products. There is in the City of Tokyo, a permanent industrial museum under the Department of Commerce, and almost every city of prominence has some form of a commercial museum of a permanent nature. Recently a train was fitted up for the purposes of a travelling exhibition. This was especially encouraged by the press, and was supported by a number of the leading commercial interests. It travelled over the various lines, and was well visited. It is a part of the policy of the Government to assist their merchants by exhibitions of their products, especially throughout China, and wherever a Japanese Consulate is established, there are a number of young commercial students attached to the Consulate, engaged in studying commercial affairs, as well as in developing and assisting in marketing the products of Japan. By this method a great number and variety of Japanese manufactured articles are being distributed and sold in various parts of the Chinese Empire. The Government considers it a part of its functions and duties to encourage Japanese commerce in every conceivable form, and the exhibition spirit seems to be one of the leading methods of rendering aid to Japanese trade. In nearly all these commercial museums and exhibitions the Government's position is that of merely aiding and assisting the manufacturer. A few months ago the Government sent to Manchuria, free of expense, a large body of business men and commecial students. These men were given every opportunity of making a special study of the markets for Japanese products, as well as of examining the possibilities of developing and placing on the markets in Japan the products of Manchuria, and it is largely by such methods as these, and their various museums and exhibitions, that the Japanese are extending their trade throughout the East.

THE INTRODUCTION OF ELECTRICITY INTO DAMASCUS.

Two years ago most people even in Turkey scoffed at the idea of electric lighting and traction being introduced and actually established in Western Asia. The Damascus-Mecca railway scheme was greeted with derision or at least with profound scepticism. However, even then to the careful observer there were signs—and these are gradually multiplying and becoming more pronounced—that the dawn of a great awakening is slowly coming in the near East. Electricity has been admitted into the Turkish Empire. The American Consul-General at Beirut says that he recently visited Damascus, and saw overhead trolley cables in the streets, and a few miles up the Barada river the station erected for the generation of electric motor power. Damascus, the oldest surviving city in the world and the most typically Oriental one in the Turkish dominions, leads in Turkey in adopting electricity for purposes of light and locomotion. The harnessing of the Barada for such ends emphasises the change which is fast overtaking Ottoman industrial and social life. On February 7, 1907, Damascus celebrated an inauguration of more than passing interest. In the presence of the Governor-General of the Province and the General in command of the fifth army corps, besides the civil and military officials, notables of the city and foreign consuls, on that day the new electric street cars and street lighting service in Damascus were handed over by representatives of the Ottoman Government, who had come from Constantinople for that purpose, to the Societé Ottomane Impériale des Tramways et d'Eclairage Electrique de Damas. It was a red-letter day in the annals of Ottoman Asia. At first the street service will cover only the distance from Salhyeh to the Meidan, some five miles through the city from suberb to suberb. Cars were to commence running on March 14th on which day the Ottoman fiscal year begins. Electric lights have been installed, and Damascus is now being lighted by 1,000 electric street lamps for which the municipality pays an annual rental of £2,750. Besides these the company have put in more powerful lights in the Grand Mosque, in the public squares, and in the Serail. Private electric lights are soon to be introduced in shops and residences. The installing company is Belgian. Some of the electrical supplies and apparatus have come from England, Germany, and France, but all cars, motors, dynamos, &c., have been bought in Belgium. Concessions for electric lighting and street railway undertakings have been granted to corporations in Damascus, Beirut, Aleppo, Smyrna, and Salonica. So far nothing has been heard of the authorisation of telephone companies.

HOME INDUSTRIES.

Masters and Men in the Engineering Trades.—A most important agreement has been arrived at between the Engineering Employers Federation, and the engineering trade unions. For nearly ten years the Federation and the Unions have been working under an agreement which was the outcome of the disastrous strike of 1897. On the whole it has worked well. If friction has not been avoided, it has prevented conflict. But the men have been anxious to secure certain modifications of the agreement, desiring the position of the unions to be more fully recognised, and the amended agreement secures this. The first condition of the new settlement is, that "The federated employers shall not interfere with the proper functions of the trade unions, and the trade unions shall not interfere with the employers in the management of their business." Here is the basis of the principle of mutuality. Next, under the agreement, every employer may belong to the Federation, and every workman to a trade union, or not, as they may desire. It follows that every employer may employ any man, and every workman may take employment with any employer whether he belongs to a federation, or a trade union, or not. No workman will be required, as a condition of employment, to declare whether or not he is a trade unionist, and the unions will recommend their members not to object to work with non-union men. And whilst the non-union man is thus recognised by the union, the employers will not object to employ any man simply because he is a member of a trade union. The employers want freedom of labour, but they know the advantage of having highly organised bodies of workmen to deal with. After the 1897 strike, and when the disputants were negotiating the agreement of 1898, the trade unions objected to leave any power with employers to make special wage agreements; but under the amended agreement they admit the right of the employers to employ workmen at wages "mutually satisfactory to the employer and workman concerned," but the rates must be adjusted to the rates prevailing in the district, for skilled men. And it is left to the trade unions, in their collective capacity, to arrange the rates of wages at which their own members may accept work. As to the numerical relation of apprentices to journeymen to be admitted into the trade, the unions do not lay down any rule, but they reserve the right to discuss the question of apprentices generally. Freedom is conceded to the employers to employ those whom they may consider suitable to work the machine tools, and to determine those conditions under which these shall be worked, but "the Federation recommend their members that when they are carrying out changes in their workshops, which will result in the displacement of labour—say by the adoption of some new machine tool—consideration should be given to the case of workmen who may be displaced, with a view, if possible, of retaining their services on the work effected, or finding other employment for them." It is agreed that systematic overtime as a method of production is to be deprecated. When it is necessary, no union workman shall be required to work more than 32 hours overtime in any four weeks, excepting upon specified emergency when it is not to be restricted. Piecework prices are to be fixed by mutual agreement, and it is agreed that piecework prices shall be fixed so that each workman's day rate be guaranteed, irrespective of his piecework earnings. It is not compulsory on an employer to give piecework. For the purpose of avoiding disputes there is to be discussion on any point of difference between masters and men, or between an official of the trade union and the Secretary of the Federation, and either party has the right to bring the matter before a local conference of representatives of employers and the unions. If this fails to effect a settlement, then either party may refer the matter to the executive board of the Employers Federation, and to the central authorities of the trade unions, who will meet in central conference at the earliest possible moment that can be mutually arranged. Meantime, "there shall be no stoppage of work, either of a partial or a general character, but work shall proceed under current conditions until the procedure provided for (as above) has been carried through." It seems to be a most admirable agreement, well calculated to avoid conflict in the engineering trades, and highly creditable to both masters and men.

The Scrap Iron Trade.—Great developments are taking place in the trade in scrap iron, copper, and other material. Every year more scrap iron, &c., comes upon the market. The rapidly increasing number of ships of old types which have ceased to be profit-making ventures, and are supplanted by up-to-date economic tonnage, and the evolution of the war ships, which necessitates the breaking up of ships of war that have ceased to be effective fighting machines, with the same principle at work in other departments of industrial life, is creating sharp competion with the crude iron produced by smelters, and it may be expected that the trade in scrap iron, which is a profitable one, will rapidly grow.

The Hosiery Trade.—The Leicester correspondent of *The Times* directs attention to the hosiery trade and the extent and character of foreign competition. Home yarn spinners are making headway in their struggle with foreign competition but there is still much leeway to make up. The home hosiery trade is at present in a prosperous condition, and important developments are in progress to meet foreign competition, and extend the colonial and shipping branches of the trade. But whilst business with Canada is increasing, and there is a steady expansion of the demand for English-made hosiery fabrics for Australian, Indian, Japanese, and Chinese markets, the home trade leaves much to be desired. Experts

estimate that at least five-eighths of the business done in hosiery in this country is in the production of foreign countries. There is reason to believe that more than half of the hose, shirts, pants, combinations, jerseys, woven under clothing, Tam o'Shanters, and endless varieties of knitted goods and specialties which are sold in Great Britain to-day are either wholly or partly of foreign production. Although in certain very important branches of the trade the goods are manufactured in this country, they are made up of yarns spun abroad, in France, Belgium, and Germany. In other sections of the trade, while the making-up is done here, the goods are composed of knitted cloths or fabrics manufactured abroad, and the remainder of the foreign imports consists of goods copied from English designs in a complete state ready for the retail trade. It is further alleged that a very large proportion of these fabrics when sold retail bear no notification of their foreign origin. English manufacturers of hosiery of all kinds, says the correspondent already quoted, are introducing new machinery to cope with the demand for low and medium priced fabrics in which the German and American manufacturers have taken the lead. In medium to low grade yarns Belgian and German competition is very formidable, and French spinners have a strong hold on a certain section of the trade. Great quantities of these foreign spun yarns are used in the manufacture of English hosiery. The Belgian and German pleating and cordon yarns made of cotton and wool are very popular, because they are cheaper than English yarns of a similar character. There is a large consumption of Verviers mule spun yarns. The Belgians turn out a soft yarn which is very regular and full as well as being nice to handle and to wear. It is very carefully produced, and is said to be better spun than the English yarns of a corresponding grade. These yarns are of cotton and wool combined, but they produce a softer and smoother fabric than if they were made of the lower qualities of strong wool only, which would be necessary to meet the price.

American Copper Imports.—On the face of it it is anomalous that the United States which produce half the copper production of the world, and export more copper than any other country, should also be among the largest importers of copper. The value of the copper imported into the United States in 1906 was 37,000,000 dols., including 6,750,000 dollars' worth of copper ore. The explanation is that the United States has superior smelting and refining facilities, and that copper from its neighbours north and south—Canada and Mexico—comes to its smelting establishments and refineries. Much of the pig copper imported is brought in for the purpose of extracting the precious metals which it contains, and some of this comes from European countries. How much of it is re-exported cannot be determined, since any important article which has undergone a further process of manufacturing after entering the United States is upon export, reported as a domestic manufacture.

The Fruit Trade.—Mr. Charles H. Fox, of Manchester, directs attention to a rather remarkable survival of protection in connection with the fruit trade, and one particular branch of it. Of the various forms in which plums are imported, the fresh fruit is admitted duty free, dried it pays 7s. per cwt., while for the tinned or bottled kind the 4s. 2d. duty on the sugar in the syrup was exaggerated to a duty of 7s. per cwt. on the total weight of the contents—water, plums, sugar, and all. This injustice, now confined to plums, originally applied also to apricots, but its application was some time ago reduced to 4s. 2d. on the added sugar, and Mr. Fox contends that the reduction should have been applied also to plums. The duty of 7s. per cwt. on plums works out in this way. The English firms bring home a foreign fruit free. They process and tin or bottle it with the syrup, paying in the operation, only the 4s. 2d. duty on the sugar they use, while the same fruit, similarly processed and packed abroad, is kept out by the duty of 7s. per cwt. on the entire contents of the tin. The protective difference which they thus enjoy amounts to about 12½ per cent. in the cost. When the attention of Sir Michael Hicks Beach (then Chancellor of the Exchequer) was drawn to the matter, he replied that "the protective character of the duty was not sufficiently marked to excite the criticism of Mr. Gladstone, nor of Mr. Bright and Mr. Cobden," but it must be remembered that a generation ago the plum import trade was practically non-existent. Mr. Asquith, whose attention has also been directed to the matter, admitted the anomaly, and added that "the question whether the Customs tariff should not be amended in respect of these duties, will receive careful attention."

Tea.—In their last tea report, Messrs. Gow, Wilson and Stanton give some striking figures as to the distribution and price of tea last year and this. For example, Indian tea. In 1906 "dust" averaged 3½d., this year 6½d.; fannings in 1906 3½d., this year 6¾d.; broken tea 5¼d., as against 6¾d.; Pekoe Souchong 5d., against 7½d.; Pekoe 6¼d., against 7¾d.; Pekoe Souchong 4½d., against 6¾d. So with Ceylon. Taking 1906 and 1907, Pekoe Souchong in 1906 was 5d., in 1907 7½d.; and Pekoe 6d., as against 7¾d. The changes in distribution are not less noteworthy. Taking the three months ended March 31, the exports to Austria fell from 48,028 lbs. to 9,751 lbs.; to France, from 85,231 lbs. to 68,174; to Holland, from 36,639 lbs. to 7,400 lbs.; to Denmark, from 31,786 lbs. to 3,585 lbs.; to Spain, from 5,289 lbs. to 480 lbs.; to India, from 405,029 lbs. to 83,860 lbs.; to the United States, from 2,245,437 lbs. to 1,425,470 lbs. On the other hand, the exports to Russia rose from 824,149 lbs. to 2,328,401 lbs. The exports to the United Kingdom fell from 21,042,874 lbs. to 20,351,492 lbs.

GENERAL NOTES.

TOBACCO IN PORTO RICO.—In reporting upon the trade of Porto Rico for 1906 (Cd. 3283), Mr. Consul Churchward refers to the increase of tobacco production and manufacture principally through the enterprise of a large Corporation operating under the immediate influence of American companies. The larger operators have been able to adopt the more expensive methods of growing, curing, and general handling, and consequently have increased the production and improved the quality of the leaf. A large proportion of these crops is grown under cover, the cost of which, although it is said to amount to some £100 per acre, is more than repaid in the enhanced yield and finer quality. These enterprises have had the effect of almost doubling the prices of tobacco lands, and of causing places hitherto considered inaccessible to be taken into cultivation. With the exception of an infinitesimal proportion all the material, raw or manufactured, is shipped to the United States.

PORT SUDAN.—In a report just issued (Cd. 3283) Mr. Hohler, the Second Secretary to his Majesty's Agency at Cairo, gives some interesting particulars as to Port Sudan, the rival of Suakin. The future of Port Sudan depends entirely upon its importance as a port of entry and a forwarding station. For these purposes it has already superseded Suakin, but the old town will die hard, if it die at all. The pilgrim traffic to Jeddah will always pass through it; this year the number of pilgrims expected is about 8,000, and as a native centre it is likely to maintain its position. The lower classes come over to Port Sudan to work, but they return to Suakin to spend their earnings. The dangers which surround the sea approach to Port Suakin do not exist at Port Sudan. The fairway is clear and well lighted, and pilots are available if desired. Pilot dues will shortly be imposed, but as yet there are no harbour or light dues. The harbour is safe, but the wharves and appliances for loading and so-on are not yet ready. Before long, however, the port will be as well equipped as Alexandria. There are at present no bonded warehouses, and the merchants are unanimous in calling for them. Whether the system to be adopted should be that which obtains in Egypt, of one large company, or whether firms should be allowed to establish their own bonded stores, is a question for the Government, but the want is much felt. Port Sudan is already at the head of a railroad running to (1) Atbara, 305 miles; (2) Khartoum, 190 miles beyond Atbara; (3) Kareima, 312 miles beyond Atbara; (4) Wady Halfa, 388 miles beyond Atbara. Other railways are projected, and with every mile that is built, the importance of the harbour increases. It seems destined to become the outlet not only for the immense territories of the Sudan, but also for a great part of Abyssinia, as well as the Congo State.

MEETINGS OF THE SOCIETY.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

MAY 30.—"Irrigation Colonies in India." By LAURENCE ROBERTSON, I.C.S., Under Secretary to the Government of India, Revenue Department. CHARLES EDWARD HENRY HOBHOUSE, M.P., Under Secretary of State for India, will preside.

APPLIED ART SECTION.

Tuesday evenings, at 8 o'clock:—

MAY 28.—"Sheffield Plate and Electro-plate." By SHERARD COWPER-COLES.

MEETINGS FOR THE ENSUING WEEK.

TUESDAY, MAY 21...Royal Institution, Albemarle-street, W., 3 p.m. Mr. D. S. MacColl, "Alfred Stevens (the English Sculptor and Painter)." (Lecture II.)
Pathological, 20, Hanover-square, W., 8½ p.m. Annual Meeting.

WEDNESDAY, MAY 22..Royal Society of Literature, 20, Hanover-square, W., 8½ p.m.

THURSDAY, MAY 23...Royal, Burlington-house, W., 4½ p.m.
Royal Institution, Albemarle-street, W., 3 p.m. Prof. Sir James Dewar, "Chemical Progress—Work of Berthelot, Mendeleeff, and Moissan." (Lecture I.)
Electrical Engineers (at the HOUSE OF THE SOCIETY OF ARTS), John-street, Adelphi, W.C., 8 p.m. 1. Messrs. F. Handley Page and Fielder J. Hiss, "The Present State of Direct Current Design as Influenced by Interpoles." 2. Mr. J. T. Irwin, "Hot Wire Watt Meters and Oscillographs."

FRIDAY, MAY 24..Royal Institution, Albemarle-street, W., 9 p.m. Professor J. A. Fleming, "Recent Contributions to Electric Wave Telegraphy."
North-East Coast Institute of Engineers and Shipbuilders, Westgate-road, Newcastle-on-Tyne, 7½ p.m. 1. The Discussion on Mr. J. L. Twaddell's paper, "Sectional Work in Ship Construction." 2. Captain W. Bartling, "Some Experiments on the Magnetic Character of Vessels."
Art Workers' Guild, Clifford's-inn-hall, Fleet-street, E.C., 8 p.m. Paper on Holbein's "Dance of Death."
Botanic, Inner Circle, Regent's-park, N.W., 3¾ p.m.
Clinical, 20, Hanover-square, W., 8½ p.m. Annual Meeting.
Linnean, Burlington-house, W., 3 p.m. Annual Meeting.
Physical, Royal College of Science, South Kensington, S.W., 5 p.m.

SATURDAY, MAY 25...Royal Institution, Albemarle-street, W., 3 p.m. Mr. Arthur Bourchier, "The Limits of the Dramatic Art." (Lecture II.)

The following corrigenda should be made in Mr. P. Schlicht's paper on "The Production of Coke and its Application in Domestic Fires," in last week's *Journal*:—Page 689, col. 2, line 48, for "Aufspitzer" read "Auspitzer." Page 694, col. 2, line 20, for "Schmach" read "Schmacks."

Journal of the Society of Arts.

No. 2,844. VOL. LV.

FRIDAY, MAY 24, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

TUESDAY, MAY 28, 8 p.m. (Applied Art Section.) SHERARD COWPER-COLES, "Sheffield Plate and Electro Plate."

THURSDAY, MAY 30, 4.30 p.m. (Indian Section.) LAURENCE ROBERTSON, I.C.S., "Irrigation Colonies in India."

CONVERSAZIONE.

The Society's Conversazione will be held, by arrangement with the Council of the Royal Botanic Society, in the gardens of that Society, Inner Circle, Regent's - park, on Tuesday evening, July 9th, from 9 to 12 p.m.

The central portion of the gardens only will be used. The Conservatory and the Club-house will be open.

The reception, by Sir Steuart Colvin Bayley, K.C.S.I., C.I.E., Chairman, and the other members of the Council, will be held at the entrance to the Conservatory, near the Broad-walk, from 9 to 10 p.m.

Each member is entitled to a card for himself (which will not be transferable) and a card for a lady. In addition to this, a limited number of tickets will be sold to members of the Society, or to persons introduced by a member, at the price of 5s. each, if purchased before the day of the conversazione. On that date the price will be raised to 7s. 6d.

Members can purchase these additional tickets by personal application, or by letter addressed to the Secretary at the offices of the Society, John-street, Adelphi, W.C. In all cases of application by letter a remittance must be enclosed. Each ticket will admit one person, either lady or gentleman, and must be signed by the member applying for it.

Tickets will only be supplied to non-members of the Society on presentation of a letter of introduction from a member.

A programme of the arrangements for the evening will be published in due course.

MULREADY PRIZE.

The Council of the Society of Arts are prepared to offer, under the terms of the Mulready Trust, a Gold Medal, or a prize of £20, for competition amongst students of the Schools of Art of the United Kingdom, at the Annual National Competition to be held in 1908.

The prize is offered to the student who obtains the highest awards in the following subjects:—

(*a.*) A finished drawing of imperial size from the nude living model.

(*b.*) A set of time studies on a small scale, from the nude living model, executed in a short time, of varied shortly sustained poses (mounted on not more than two imperial size mounts).

(*c.*) A set of studies of hands and feet from the living model (mounted on not more than two imperial size mounts).

(*d.*) Drawing from the life, including memory life drawing done at the Examination in May, 1908.

No student will be eligible for the award who does not pass in the Examination (*d*) in drawing from the life, and who does not obtain an award for (*a*) the finished drawing of imperial size from the nude living model. The other two subjects are optional.

The works must have been executed between 1st April, 1907, and 31st March, 1908.

The recipient of a prize awarded under this trust in 1892, 1893, 1896, or 1903, cannot compete again.

The drawings, &c., are to be submitted, with other school works, in the usual manner to the Board of Education, South Kensington, in April, 1908. Each competing drawing must be marked "In Competition for the Mulready Prize," in addition, to being labelled according to the Regulations of the Board of Education,

PROCEEDINGS OF THE SOCIETY.

APPLIED ART SECTION.

TUESDAY, APRIL 30th, 8 p.m.; J. C. WEDGWOOD, M.P., in the chair.

The CHAIRMAN, in introducing the reader of the paper, said that the subject of joinery and furniture making was a topic which was very near to them all, because the elements of comfort and of ease in life depended a good deal on the state of their furniture. They all wanted their doors to be quiet in closing; their casements to shut free of draught, their sashes to move silently and easily, and they wanted their articles of furniture, say a chest of drawers, to work without the usual aggravation such things caused, when they were not well made. The tendency of life at the present moment, was rather leading to the extinction of the crafts of joinery and furniture making; he thought the carpenter, the joiner, and the cabinet maker were virtually disappearing over the horizon. The carpenter and joiner was attacked on two sides. The first side, which he might call a double one in a sense, was the very transitory way in which the normal or typical man lived at the present time; he inhabited a house he did not own, only taking it for a term of years, and meaning to get out of it either for better or worse, as the case might be. The things that he put into the house were things he did not care about; the furniture he got for to-day would not suit the smaller or bigger house he moved into afterwards, and so he was content with rather ephemeral products. The pictures on the walls were probably only photographs, the books in his library were borrowed from the circulating library, and all his things generally were placed in the house temporarily. No craft could exist under such conditions; if such was to be the demand, the supply would always remain mechanical. At the present time things were jammed together by hydraulic pressure and kept tight with glue. The other difficulty on the same side, was that those who did care about furniture were full of a kind of crammed-up knowledge of what had been, and they, therefore, insisted on having models made of acknowledged masterpieces. A really fine craftsman ought not to be asked merely to copy. It was quite another thing to tell him he could take inspiration from such masterpieces, to try and absorb the spirit in which they were made, and then produce other articles, but if he were asked merely to copy a thing, it took the starch out of him and left him a limp and disconsolate person. In the end he would probably succeed in making an able forgery, but the forgery would be a lifeless one. The other attack on the craft of furniture-making was an interesting one, namely, from the theoretical medical side. If the doctors were to be believed, people were doing very wrong in living in substantial houses built of good solid material and brickwork, as they harboured the deadliest enemies of mankind in the shape of microbes. The doctors implied that people ought to live in houses which were made of some material which could be very easily and safely burnt at the end of a year or so. It made a great difference to the man who was going to spend his life in constructing articles like furniture when he knew they were to be looked upon as a possession and a treasure of the possessor and his descendants. They all wanted furniture in their houses which they could be proud of, and it was impossible to be proud of any of the usual articles of furniture to be bought nowadays. In olden times people had their pieces of furniture; they spoke of them very respectfully; they treasured them, sought for them, kept them in good repair, and left them in their wills to esteemed descendants. He hoped the information obtained from Mr. Green's lecture would be the means of increasing everyone's respect for furniture, and thereby open up the field for careful thoughtful work, and thus encourage the artificer.

The paper read was—

JOINERY AND FURNITURE-MAKING.

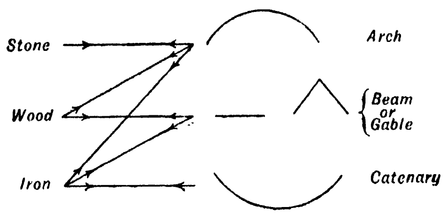
By A. ROMNEY GREEN.

Joinery is one of those crafts which have to do with the building or fitting, the decoration or furnishing of fixed and permanent structures. In this architectural process, it is found that certain materials are better adapted than others to certain purposes. The upright walls of the structure, for instance, can be built of almost anything; but stone or brick are generally used because they are better adapted for the purpose, and much more abundant than any other material, and, by reason of their weight and fragility, are useless for non-architectural purposes. But to use stone or brick for the roof, or the upper floors of a building, is a more questionable and difficult matter. The difficulty consists in carrying the heavy and brittle material under the downward action of the force of gravity, from any one point to another which is not vertically above it. With stone or brick this can only be done, if the two points are any considerable distance apart, by the use of the arch or vault; and this is always an expensive process, whilst in the case of floors it involves a great waste of space and material between the floor and the vaulted ceiling.

But there is another material, wood—light and fibrous, and strong in the direction of its grain, which can easily be carried in a straight line, and therefore with the least possible waste of space or material, from one point to another at some distance off in a horizontal or an

oblique direction; and, since this material is also fairly abundant and quite easy to work, it is generally the best material to use for the roof and floors. Iron (or other metal), the third material available by the architect for structural purposes, differs from stone and wood in that it is much stronger, even in proportion to its weight, though it is also heavier, and in that it is equally strong, whereas stone, as a rule, is equally brittle in all directions, wood standing between the two as strong in one direction alone. For this reason, iron differs both from wood and stone in that it can assume not only the arched and the rectilinear, but the hanging or catenary form, as in a suspension bridge, between one point and another not in the same vertical line. These important properties of the three materials may thus be represented by the following diagram:

FIG. 1.

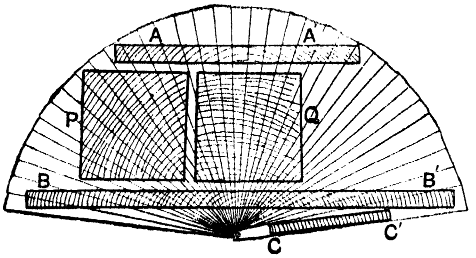


from this it appears that the most characteristic, though not always the only possible, use of each material in solving the given problem is indicated by the corresponding form. Now, it is a principle of the first importance in the architectural crafts that no material should be put to any but a characteristic use; so that in the spanning of aperture, where the catenary for architectural purposes would be worse than useless, iron should have no use at all. A good instance of the violation of this principle may be seen in the entrance hall of the Natural History Museum, South Kensington, where the proportions of the arched system are utterly spoilt by the use of iron, on a scale quite insufficient had these been of the right material, in the uppermost series of arches.

It is in accordance with this principle, to which I shall refer again, that wood may be used, though not in that arched form which is characteristic of stone, for the roof and floors of a building. But the art of using wood thus for structural purposes is the art of the carpenter; not that of the joiner, with which I am dealing to-night. The work of the joiner only begins when the shell of the building is finished; it consists in providing doors, window frames and sashes, handrails, and other permanent fittings. And though in roofing a building we may sometimes hesitate between the stone vault and the timber gable, there is no doubt whatever that for doors and handrails, as also for such portable furniture as chairs and tables, wood, by reason of its strength, lightness and beauty, and of its pleasantness to the touch as compared with stone or metal, is very much the best material.

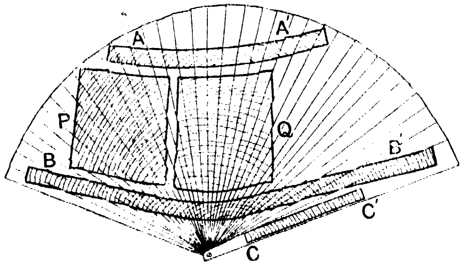
Now the nature of each of the building crafts is of course very largely determined by that of the material used; and wood has several peculiar properties in addition to those which I have already described. One of the chief requirements of a door, which has exactly to fill a given aperture, is that it should remain constant both in size and shape. And one of the most characteristic properties of wood, the material which in other respects it is most convenient to use, is its natural disinclination to constancy either of shape or size. Wood is a fibrous material any prism of which cut with its axis parallel to the grain will be usually of constant length but of variable cross-section. The area of its cross-section, that is to say, will continually decrease as the wood dries, and even after the wood is dry it is sensitive to changes of atmospheric condition, swelling or shrinking as the moisture of the atmosphere becomes more or less. And not only is the cross-section of such a prism variable in area, but also in shape. This is due to the fact that thin laminæ of shell-like cellular tissue are distributed through the substance of the tree at small and fairly regular intervals in planes which pass through the heart; and that these laminæ or medullary rays tend to resist the shrinkage of the wood in the direction in which they lie. These laminæ, that is to say, draw together as the wood dries, but do not very much contract in their own dimensions. As seen in cross-section, where, either to the naked eye or under a microscope, they appear as radii of the annual rings, these rays tend to close upon one another like the ribs of a lady's fan. Some of the results of this tendency are illustrated in my first slide (Fig. 2). The card fan is to represent the cross-section of an oak tree out of which have been cut, whilst the wood is still green, the three flat boards, AA', BB', and CC', and the two square posts, P and Q. As the wood dries the medullary rays—the leaves of the fan—close upon one another thus, with the result that the boards, AA' and BB', contract in width

FIG. 2.



and become convex towards the centre or heart of the tree. These deformations are more pronounced in AA', and in the middle of BB', where the rays cross it obliquely; whilst CC', and the outer parts of BB', which lie in the direction of the rays will hardly be deformed at all. The square posts, moreover, are no longer square, P, which the rays cross in the direction of its diagonal, being further deformed than Q, which the rays cross in a direction parallel and perpendicular to its sides.

FIG. 3.



My second slide shows two actual cases of these deformations. It also shows a square post which contains the heart of the tree, and in which, since the medullary rays cannot close up all round the heart without somewhere opening a crack in the log, we find the expected crack opening, as we should expect, between the heart and one of the nearer surfaces. There are cracks also on other sides of the log, but these are due to the fact that the log dries from the surface inwards, and they will close up again, whilst the other shake will open still further as the log continues to dry; and there are cracks called "heart-shakes," starting from the heart but not reaching the faces of the log, which would have been there when the tree was first cut down, and which I will not try to explain.

From these examples of the curious behaviour of wood we can draw some important morals. If, for example, a post which the rays cross diagonally is to form the leg of a table it should be set so that the rays are tangential, and not normal, to the circumscribing circle; for on this will depend whether the outside shoulder joints between the leg and the rail opens or not as the leg dries. But the most important moral of all is that which relates to the cutting of a flat board, especially when it is most desirable, as in the case of a table top, that the board should neither warp nor shrink. In this case, as you see on reference to the model, the board should be in a plane which lies as near as possible to the heart of the tree, though on one side or other of the part nearest the heart, so that the medullary rays are as nearly as possible parallel to its surfaces, as they are in this illustration. For when thus cut the board will have little inclination to warp, and its shrinkage, as the rays close upon one another, will affect the thickness, where it can not be great, rather than the width of the board. And here is an admirable instance of the poetic justice of Nature; which generally contrives that what is rightly done from any one point of view shall be rightly done from every other; and in particular that the requirements of use and beauty shall be satisfied at the same time. For it is when the board is cut in this way, that the rays, if they are visible at all, crop out most beautifully on the surface, as they do here, in great flakes and splashes of light; and, strangely enough, there is one wood, oak, in which the rays are much more plainly visible than in any other, and it is just this wood which is more liable than any other to warp and shrink when improperly cut. Moreover, the board is more easily sawn out or rent, and very much more easily planed up, when it is cut in this way; so that there are three important reasons, any one of which would be alone sufficient, for cutting as many boards as possible out of an oak log in this way rather than in any other.

I will show you, then, how this may be done, assuming that we wish, as we naturally should do, to cut boards of various thicknesses out of one or any number of trees. But first let me show you how an oak tree is generally cut up by an English timber merchant as an example of how it ought not to be done. We are justly proud of our English oak as the finest timber in the world; but I am sorry to say that if we see an oak tree cut up in the right way we may be almost certain that it was not cut up in England. One thick plank, containing the heart shakes, is cut out of the middle of the tree, because, they

say, boards cut here would be useless on account of the heart shakes; and the rest of the log is cut into boards parallel to this plank. The consequence is that only two or three boards on each side of the plank—only five or six altogether out of the whole tree—are cut in the right way; and that the thick plank, though it may be used for fencing or other outdoor work, is almost useless to the joiner, as it is penetrated with shakes throughout. But it is just where they take this thick plank that we can cut the best figured, and, but for the heart shakes, the most valuable boards; and since a long heart shake, which may spoil half the thick plank, will only spoil a small part of each of the thin boards, this is clearly the right thing to do; cutting the thinnest boards we want, for door panels, &c., out of this part of the tree, and so making the best possible use of it. As soon as we are clear of the heart shakes we can cut thicker stuff to be used in larger pieces for table tops, &c.; above and below these we cut two sets of boards in the vertical plane, narrow but beautifully figured, and exactly suitable for the stiles and rails of doors or other framed structures; and outside them again we can cut table legs or other posts, though remembering their tendency to deformation as the wood dries. This is merely an intelligent variation of the ordinary Continental and American method of cutting wainscot oak, cutting it, as they say, "on the quarter."

I will now return to the question of door making, in connection with which I can illustrate most of what I have to say on the subject of joinery. From what I have said you will see that it is impossible to make a good door of a single board, even when sufficiently wide stuff is available. It would shrink, it would warp, and it would be very liable to split longitudinally if subjected to a violent shock in slamming, or by a determined house-breaker. The problem here, as in every wooden structure, is to obtain that strength and constancy of dimension in all directions which the material possesses in one direction alone. This may at first be attempted by screwing or bolting other pieces of wood with the grain horizontal—ledgers as they are called—to one side of the original wide board. But even so the tendency of the latter to shrink will probably result, either in its splitting, or in its buckling the ledgers; for the strength of this tendency is almost inconceivable till one sees the effects of it. The next attempt, therefore, to solve the problem, will be by making the width of the door in several pieces, bolted, as before, to horizontal ledgers, but with tongued and grooved or over-lapping edges, so that the pieces may shrink separately without buckling the ledgers, or showing daylight between their joints. In this case, however, the door will obviously require bracing; the lapped edges of the vertical members will afford a good opportunity for moulding; and we get at last a door such as that shown in the following slide. This is the first type of a thoroughly good door. It will always be popular on the score of cheapness, and is actually often preferred for its intrinsic merit to the next and more elaborate type. My own objection to it is that on the side on which I cannot see the construction I wish that I could, and on the side on which I can see it, it is generally so clumsy, that I wish that I could not. The fact, moreover, that its construction involves the use of bolts or screws gives it just the same inferiority to the next kind of door that a packing-case has to a chest of which the sides are dovetailed.

The great virtue of the framed and panelled door is that its construction is visible on both sides; that it is highly characteristic of the material, and that it does not involve the use of any other—it can be made without screws or nails. The most elementary form of such a door consists of five pieces of wood, four thick narrow pieces, grooved on their inner edges, and mortised and tenonned together, to form the frame, and one thinner and usually wider piece, the panel, fitting into the grooved frame. I have here a sample of such a door in process of being put together. The mortises are usually cut on the vertical members of the frame, the stiles, and the tenons on the horizontal rails. Here, if the groove is deep enough, and the panel does not quite touch its inner surface, it is clear that the panel is free to shrink or swell without leaving or deforming the framework, the inner edges of which will form a rectangle of constant size; and if the stiles are sufficiently narrow, the tendency to alteration of the whole width of the door will be much less than that of a single board of the same width.

Before describing the possible elaborations of this simple form, I must call your attention to certain small points which should be observed in construction. The tenons may either be carried right through the stiles and fastened with wedges, as in the specimen, or carried only part way through, when they are called stub-tenons, and fastened with wooden pins. The former is the strongest,

and in modern joinery the most usual, method, but it has this danger: that if the stiles are not quite dry, they may shrink away from the shoulder, leaving an open joint which disfigures and weakens the door. The usual recipe for providing against the opening of the shoulder joints is to say that the wedges should be so cut as to fit more tightly at their inner than at their outer ends. A safer precaution, however, is to put saw cuts in the tenon and insert the wedges in these cuts, instead of outside the tenon, as in the next slide; and either to use glue on the wedges only, or, at all events, to see that there is no glue on the upper and lower edges of the tenon at its outer end. In this case the tenon is really dovetailed into the stile instead of being merely held by compression, as it is by the usual method; and if the stile shrinks, it is just as sure to shrink towards the shoulder rather than away from it, as a ball is to roll down hill rather than up. If, however, the wedges are placed in the usual way, it is a good plan to use glue on their inner surfaces only, so that they become part of the tenon rather than of the stile, with the same advantages that are obtained by the other method.

By the use of intermediate members of framework, vertical, horizontal, or oblique—rails and muntins, or struts and braces—with the requisite number of panels, this type of door may be elaborated to any extent.

Here are some examples of doors and other panelled structures from the Victoria and Albert Museum kindly lent by the Board of Education, which I have arranged in chronological order, with the purpose of illustrating and trying to explain the extraordinarily rapid change in the spirit and art of wood-working, as in the other architectural crafts, which took place between the fourteenth and eighteenth centuries.

All manual or productive work is of two kinds, which may be distinguished as the indirect and the direct, or as the preparatory and the creative. To sharpen a chisel, for instance, is work of the first kind; to use it work of the second; to make a door is work of the second kind; to draw the door, or to make any mere instrument of production, such as a mitre-board, is work of the first kind. And corresponding to these two kinds of work there are two extreme types of workmen. There is the enthusiastic and hot-blooded, the foolish and poetic, type of workmen, who is in such a hurry to get to the creative work, that he will spend the least possible time over any preliminary operation, and that not till the last possible moment; he will sharpen no tool till he actually needs to use it, and make no working drawing, nor waste his time upon any time-saving contrivance, if he can possibly do without it. And there is the conscientious and methodical—shall I say the diplomatic or prosaic?—type of workman, who has realised that time well spent in preparation may be more than saved in the actually productive work; who makes sure that his tools are all sharp and in order, his working drawings and templets complete, and every possible labour-saving expedient considered and prepared, before he touches the wood at all; who cuts out all his parts before he begins to plane them, and fits them all together before he will carve or mould them; and who adheres strictly throughout to his working drawings, whether they are his own or another's. These are the two extreme types of what I may perhaps call the natural and the civilised craftsman; the one with his attention wholly fixed on the end desired, and working directly to that end with such few and simple tools as he already possesses; the other constantly considering the means to be adopted, and working therefore with continually more numerous and complex instruments; the one wholly possessed by his conception; the other equally content, so long as it gives him an opportunity of using his latest and most ingenious tool, in working at that of another man; the one, therefore, freely and fully expressing himself in the finished product of his labour, by which alone he is finally judged; the other expressing himself, by the way, in many practically unrecorded activities, and producing finished work of a less human and individual character because of the more specialised and mechanical nature of the tools employed.

The moulding plane, which has been so much used on these last two doors, is a good example of what I mean by a highly specialised tool. I do not know the date of its introduction, but it was certainly long subsequent to the introduction of mouldings. Look again at the old pew ends, or at the old pulpit*, and you see that they are covered with mouldings for which the moulding plane could not have been used at all. For the moulding plane can only move in a straight line, and cannot very well be stopped until it gets to the end of the wood. It might have been used, for instance, to cut

* Photo 15947 in S.K.M. catalogue.

the moulding on this rail, but not that on the stile, which must have been cut with chisels and gouges, in order to turn the corner in that way. Indeed, the whole thing is obviously the work of men who were quite content, on the one hand, with these simple tools, and whose heads, on the other hand, were so full of patterns that no two of the carved panels, nor of the vertical moulded ribs, are anywhere of the same design. And though you will probably not think that any of the detail is as good as it might be, you will all admit the charm of mingled richness and rudeness, the vast amount of individual character, that there is in the whole effect. The expression of character is direct. It is impossible to imagine that this pulpit was designed by any but the man who made it, or that full-sized working details were drawn out even by him. Rather it grew as he worked at it, and his work was spontaneous and direct. He had not studied nature, this man, nor had he been taught design, but he seems to have been born with the tools in his hand, and ever since to have been dreaming of leaves and feathers, and knotted tree trunks, and half human, half bird-like, inhabitants peering at him from between the branches. Except, perhaps, in this one panel, which seems to be of later date, he worked mainly to please himself, with the result that the whole thing is alive, and still instinct with the soul of its forgotten author.

This fine old door (S.K.M. 18261)—also French—is of about the same date, and of very much the same character; but there is one premonition of the coming change in that the plough has apparently been used on the framework of the door in the capacity of a moulding plane, though the device of making this mechanically cut moulding continuous by means of mitreing has not yet been attempted.

In this seventeenth century panelling (S.K.M. 19305), and in this next (22041), an eighteenth century door, it is clear that a complete change has come over the spirit of woodworking. This change may be partly explained — or shall I say, more fully described?—by saying that the craftsman has begun to prefer the more complex and highly specialised to the simpler tools. He has begun to realise that time spent on the preparatory stages of his work may often be more than saved in the actually creative processes; he has learnt to work with a deliberate and increasingly elaborate adaptation of means to ends in which his genius has more than half expressed itself before the work of creation begins. He has found, for instance, that if he buys or makes himself a moulding plane he can cut mouldings of a certain kind, very much more quickly and accurately than he could do with the gouge and chisel. And, since his moulding plane will not go round a corner, he has begun to mitre his mouldings. And for this purpose he finds that he wants a mitre-box and a specially fine-toothed saw; and that even then his mitres have to be planed, so that he must make himself a mitre-board, and for that, again, a particular sort of plane.

Now all this has an effect on the craftsman's character. Between the use of a moulding plane and of a gouge or chisel there is all the difference between work and play. Leave a man with a sharp chisel alone in the same room with a sharp-edged rectangular board, and he will be just as irresistibly moved to attack the sharp edges of that board with his chisel as the boy to notch the edges of the school desk with his knife. To hack with something—with anything—at all sharp edges and corners is an instinct of the human race. But I do not think I ever yet met the natural man who was irresistibly attracted to the use of the moulding plane. The moulding plane is a very different instrument from the pocket-knife or the chisel. These latter a man can use very effectively for a short time in a certain way, and then use them quite as effectively in some other way, or, if he is inclined to be lazy, stop using them altogether. But when he begins to use the moulding plane on the sharp edge of his board, he must either at once or in a succession of strokes go the whole length of that edge; and he must go the whole length of that edge many times, his moulding plane traversing always exactly the same path at exactly the same inclination to the face of his board, to produce an effective moulding. This is something very like hard work; and when the moulding is cut, the workman—unless he also made or designed the plane—has not expressed himself, except, if he has been successful, by his fidelity to the conception of another man. His work has been mechanical, and the result is highly mechanical as compared, for instance, with the richly-cut ribs of the French pulpit. And before he can make such a door as either of the two last—for the sake of brevity I will call the section of Jacobean panelling a door—this mechanical operation has to be many times repeated; and, worse than that, his plane will have to be

frequently sharpened. To sharpen a knife, a chisel, or a gouge, is a simple, and by no means a disagreeable task; but to sharpen the iron of a moulding plane so as not in the least to alter the delicate contour of its edge, which must everywhere project exactly the same small distance beyond the shaped sole of the plane, is the task of a mechanic, a slave—or shall I say of a saint? — rather than of an artist and a free man. Of the true artist, as of the poet, we must say that he is born, that he is not made; but the exact contrary is true of the kind of artist who can turn out such doors as those. Not only the cutting of the mouldings, but the mitreing of their corners, whether "stuck" as in the one door, or "planted" as in the other, and the construction of the whole door, is mechanical, unimaginative, and tedious to the last degree. And it is especially interesting to notice—only in looking at the photograph of these panellings I did not at first notice sufficiently—how this mechanical and unimaginative character of the craftsman which is fostered by the use of such instruments as the mitre-board and the moulding plane, comes out also when he handles—or wishes it to appear that he has handled—the superior tools; for his attempts at decoration on the Corinthian pilasters and on the central panel, (S.K.M. 19305) which, as far as the tools are concerned, might have been freehand, are just as hard and monotonous as his plain flat panels and his painfully cut and mitred mouldings. Even his patterns do not express the man, but have obviously been traced and repeated — so at first I thought — from the full-sized drawings of some academic designer. But here perhaps I did an injustice to the academic designer, and I certainly underrated the sophisticated ingenuity of the artisan. For on looking more closely I see that very little of this decorative work has been done with the carving tools at all; it has been cut out with a fret saw and glued on to the structural members, some of the rosettes only having been afterwards carved so as to heighten the artifice by which I was at first deceived. And here, you see, some of this applied ornament is peeling off, in obedience to the natural law which always at last exposes the artificial and insincere.

So far I have only partly explained this great change which has come over the spirit of wood-working. I have been careful to give the technical explanation only. I have explained it as a tendency to the specialisation of tools, the elaboration of means and methods, the spending of thought and time and energy on preparatory rather than on creative processes. I have said that the craftsman expresses himself in the instruments, the bye-products of his activity, rather than in those more enduring results by which alone he is finally judged, since these are all the while the true end of his labours; and that the finished product of his work would be naturally less human, less richly interesting, more formal and mechanical, merely on that account. Whether or not the later work is also less beautiful is perhaps a question of individual taste. A great deal of beautiful work, especially in furniture making, was done during the seventeenth and eighteenth centuries; and, speaking generally, I do not wish you to think me prejudiced in favour of Gothic as opposed to Renaissance art. I only ask that all art shall be natural and good; not consciously—it can never be that—but quite unconsciously the expression of character, as undoubtedly is the work of the great painters and sculptors of the early Renaissance period; and as often was that of the eighteenth century furniture makers when they used their improved appliances to produce work which was, not cheaper, but really better and more useful, than that which had gone before. And so far I have only said that the specialisation of tools has a strong tendency to make this expression of character less direct—the finished products of the tool less human and alive. But I do believe, too, that the arts are well called the "humanities," and that the more beautiful of two works of art is always the more human or humane. Everywhere and in everything, in our houses and in our furniture, as well as in our books or our friends, I believe it is life, it is soul, which we look for, and by which we live. I believe, therefore, that the change which I have traced in the art of wood-working is decadence—is a change for the worse. And if you agree with me, and if you are content with the explanation I have tried to give—if we assume that the craftsman as a free agent has been himself responsible for the tendencies I have just described—then we must believe that every art contains in itself the seeds of its own destruction. This, however, is not only a most unhappy, but a most unwarrantable conclusion. This rapid decadence of the crafts which has characterised the western civilisation of the last four or five hundred years is anything but a normal phenomenon. In Egypt and Asia the

industrial arts have often flourished for untold centuries, or even thousands of years, without any such signs of diminished life and energy as have been traced in these illustrations. And, to come nearer home, here is a Norwegian chair of the tenth century (S.K.M. 23713), and here a Norwegian butter-tub of the eighteenth century; and the spirit that breathes from these two lovely works, separated though they are in date by eight hundred years, is so nearly identical, their difference of functions allowed for, that they might almost have been made by the same man. Here, on the other hand, is a French chair (the ugliest thing I could find in the South Kensington Museum—26488) of almost the same date as the beautiful French door, but instinct and hideous with an utterly different feeling, which, since it is carved all over, and must at that time have been carved by hand, cannot be wholly accounted for by the specialisation of instruments.

If we go back again over our illustrations, you will see, I think, that those which I have already attributed to the natural or poetic type of craftsman as opposed to the civilised or prosaic, and to the direct as opposed to the indirect method of workmanship (and with these I include the Norwegian articles), resemble each other, but differ from the two later doors, as also from the French chair, in that they bear no witness to the existence either of academic influences or of class distinctions. We have here, in fact, two distinct kinds of art—the two kinds of art which Mr. Lethaby, I believe, lately distinguished as the "distributed" and the "condensed," but which, since I was unfortunate enough not to hear his paper, and do not wish to misapply his terms, I had better continue to call the natural and the civilised, or might describe better still, perhaps, as the voluntary and the forced. The first, the natural or voluntary kind of art, is done on their own initiative by the people for the people; by the craftsman for his own family or township, for his church or his Guildhall; at the worst—or shall I say, at the best?—for some local magnate or liege-lord with whom he had personal contact, and between whom and himself on both sides was recognised a social tie; and if the Norwegian chair was made, as it should have been, for a king, that king was, like his subjects, a viking; he was much more truly, I imagine, one of his people than were the kings of the Middle Ages. But the two later doors and the French chair, though by no means worthy of kings, bear internal evidence, as it seems to me, that no social tie was recognised at all between those who made them and those for whom they were made. They bear witness to an over-emphasis of class distinctions which is just as fatal to art as it is to manners and conversation in begetting everything that is over-formal or over-florid at the expense of everything that is natural and sincere; and which is even more fatal to art than that tendency to the over-specialization of tools which I have already described. The freedom of execution, the geniality of the earlier work, as compared with the formality or floridity of the later, is the geniality and freedom of the man who is working, not only with simple rather than with highly-specialised tools, but for kindred spirits of his own acquaintance rather than for unknown task-masters of greatly superior rank, and different habits of life. Of such an unknown task-master it is naturally assumed by the humble craftsman that he will require in all his furniture and apurtenances an almost superhuman perfection of workmanship, whether simple or ornate; he cannot imagine that this superior creature is possibly a man of like tastes with his own, who might be wonder-struck by the same half-suggested beauty or charmed by the same conceits.

The decadence of Gothic art is a mysterious phenomenon, and there are doubtless many people in this room who know more of its history than I do. I am only anxious, if possible, to absolve the craftsman; I am sure that he was not solely responsible; that there were social causes at work, and that these were at first political rather than academic or economic. But with the Renaissance of art and learning the craftsman became subject to another and more far-reaching than this political tyranny; to that of antiquaries, scholars, and architects who, in a spirit of noble though mistaken enthusiasm, deliberately proceeded to force on him traditions utterly foreign to those which he had himself developed. To impose on the craftsman of one age and country the traditions of another utterly dissimilar in climatic and social conditions would always be fatal to his own genius and to his dignity as a free man; but it was especially so in our own case because the usurping traditions were those of the slave-holding communities of Greece and Rome and favoured our already existing bias to formality and mechanical finish in that they had been adjusted by tyrannical masters to the capacities of the helot races. In what

I have called voluntary art, the craftsman, as I have pointed out in the case of the oak pulpit, was obviously his own designer; though in this capacity he made no painful effort to be original; his individual genius was always partially subject to the authority of his great traditions; and the importance of this principle, that the craftsman should be his own designer, whilst subject to his own traditions, it is impossible to over-estimate. Even by the draughtsman himself a perfect design can never be made on paper; a design, in fact, can never be said to be made until it is carried out. A hundred opportunities occur during the progress of a work of art for improvements and modifications, for just those little touches that make the whole difference between success and failure, which cannot be foreseen until the work is actually in progress. No true craftsman will ever adhere exactly to a cut and dried set of full-size working details, even of his own design; he will be continually revising his first conception according to the promptings of his spirit, the weakness of his flesh, or the stubbornness of his material, as he goes along. If, for instance, he has intended to use a large piece of wood for a certain purpose and finds that he has not got it, he will probably make a virtue of necessity, and a pattern of his small pieces. If, in cutting out a bracket or angle piece, he finds that the grain of the wood permits a sharper curve than he had hoped for, he will alter his design accordingly. And thus, by taking advantage of his opportunities, accommodating himself to his material, working always in the direction of least resistance, he will produce an article of a certain natural, inevitable, almost fatal beauty, superior to that of his own more arbitrary first conception. It is this slow evolution of types, and adaptation of forms to materials, this constant elimination of everything that is unfit either from a decorative or a constructive standpoint, that constitutes a sound tradition; and such a tradition can only be developed and maintained by successive generations of craftsmen who are their own designers, and who are also in direct communication and sympathy with the public for whom they work. The work of the professional designer, carried out by the mere mechanic, may usually be known by one or more of the following characters: by that symmetry and formality, and dull repetition of parts, which saves so much labour in drawing, and takes so much interest out of the creative process; by that cheap originality or eccentricity which is so easy to the man who has substituted pencil and paper, for the stubborn material and the cutting tool, and who is not therefore compelled to suffer in his own person the penalties of his own caprice; or, at the best, by a certain violence of intention, an abuse of material, and waste of labour, which suggest the strategist who conducts a campaign, not from the saddle but from the arm-chair, and without sufficient reference to the movements of the opposing forces. Beauty in art, as in nature, is organic; it is seldom either quite geometrical or quite capricious; it grows, it cannot be manufactured; its manifestations are not to be compelled but awaited; like the kingdom of heaven, it cometh without observation. And till this principle, that is, that the craftsman must be his own designer, is thoroughly grasped and applied we can have no national art.

I have now attributed the decadence of the crafts, previous to the industrial revolution, to three co-existing tendencies; to the specialisation of tools, the over-emphasis of class distinctions, and the growth of academic influences, and it was merely the more rapid development of these tendencies, following the invention of the steam-engine and power-driven machinery, which constituted the industrial revolution. Not only the tools are specialised but the workman's functions; the man often becomes not a tool merely, but a veritable machine. And this inhuman degradation of the craftsman, who was once in the full exercise of his creative faculties, perhaps the most nearly godlike of all God's creatures, is justified in the name of economy; and this though the average national income per head has doubled and trebled and, perhaps, quadrupled itself since the golden age of mediæval art and handicraft. The result we know. We know what fabulous sums are now given for old pieces of furniture, because persons of taste will pay anything rather than tolerate in their houses the abominations of modern furniture. We know what these people suffer because there were some things which our forefathers did not make—how they cannot enjoy the use of a billiard table, a grand piano, a roll-top writing table, or even a comfortable chair without importing into their museums of art elements of vulgarity and discord which might very well break their hearts. We know how almost impossible it is for us to restore an ancient building without spoiling it so utterly that it would have been better destroyed. We

know how at the first contact with western commerce and civilisation the arts of the great peoples of Asia, or of the more remote peasant races of Europe, which had flourished, as I have said, with undiminished energy for hundreds or even thousands of years, are suddenly withered away as if by magic, and beyond hope of revival. And even when, independently of economic considerations altogether, we put forth our best powers to produce work, let us say, for the great Paris Exhibition, this is the kind of thing we do. (S.K.M. 22350, 22358).

Various attempts are being made, as you know, to remedy this state of affairs. Here, for instance, are some illustrations of the work of Mr. Sidney Barnsley, who makes, as I think everyone will admit, the best furniture that is now being produced at all. Mr. Barnsley makes the strongest possible protest against modern industrial methods, not only in eschewing the use of all machines, and, of course, in designing his own work, but in executing it throughout entirely with his own hands. But all work in applied art is the work, not only of the individual craftsman, but of the whole community; and in spite of their richness and fine proportions the formality of these two beautiful cabinets suggests, I think, that Mr. Barnsley has not the confidence in his public which would enable him to let himself go; to express himself with the freedom and geniality of the mediæval craftsman. Mr. Barnsley, in fact, like everyone else who is trying to do good work at the present time, and who has also to make a living at it, has to work for a rich class of very refined and superior people; for people with whom the craftsman, or anyone who works with his hands even if he belongs to their class by birth, as now-a-days he often does, can have very little in common. For when a member of this class begins to work with his hands; when he begins to see life from the real, the industrial, side—from the point of view of the people who produce the necessaries of life—the things without which the superior and ornamental class could not exist for a day—he soon finds that his whole outlook upon things in general is suddenly and strangely transformed. What was important to him is now trivial, and what was trivial is now important. In particular a whole class of things which were formerly almost beneath his notice—chairs and tables, and cups and saucers, and pots and pans, and wheelbarrows and ladders, speak to him now continually; they have become biographies and histories, of the joys and the sufferings, the virtues and vices, of their makers, his fellow men. He suddenly realises that it is the producer, and not, as he used to be taught, the consumer, who is the important person. If he is a furniture maker, he finds that he wants to make furniture for other people who also work with their hands; for the kitchen rather than for the drawing-room, and for the farmhouse or the town hall—rather than for the town flat or the residential villa. So that when I said that the decadence of the crafts was very largely due to the over-emphasis of class distinctions, I might have put it more simply and said that it was due to the fact that people have stopped using their own kitchens themselves. I have neither the time nor the temerity to drive this point home this evening; nor am I qualified to preach a theory that I do not practise; but I merely give you the facts.

Less than a hundred years ago, the Norwegian peasant, before his economic man had been tempted and his taste corrupted by the wares of the British capitalist, produced kitchen and other furniture for his own use of which this butter-tub is an example. And when Mr. Barnsley, instead of making drawing-room furniture for other people, makes furniture for a kitchen which he himself uses and lives in—for a living-room—a room which is a study and a library as well as a dining-room and a kitchen—he makes furniture like this for it. Even this furniture, beautiful and interesting though it is, is severe and plain as compared with mediæval work; but that only illustrates the difficulty of the craftsman who has to start from the beginning on his own account. Had Mr. Barnsley inherited four out of these five pieces of furniture, the time and energy expended on the five he might have put into one alone. Each piece, probably, would have been richly carved; and that the more easily and successfully because the inheritance of living traditions would have been even more valuable than that of the furniture itself. All art tends to be both expensive and artificial in the absence of true traditions, because then the craftsman must stop to think before he can act, which takes time, and is in any case a dangerous habit; and this loss of tradition is even more fatal to decorative than to structural excellence. It is for this reason that wood-carving is almost a lost art at the present time, and one, I believe, which Mr. Barnsley has not tried to revive. I have the

greatest admiration and respect for the work of Mr. George Jack; but wood carving in his hands is a fine art; I feel that it is almost too refined and beautiful; it is work that it would be hopeless to emulate, that could never become traditional, and that, in any quantity, would be almost oppressive to live with. I feel that if it is yet possible that the art of wood carving in an architectural and popular sense of the word be revived at all it must be rather in the spirit of my friend Mr. Godfrey Blount. It is much less refined and elaborate work than Mr. Jack's, but full of irresistible life and energy. It is nearer to the mediæval work in spirit than almost anything I know, just because it is play rather than work. The tools used are of the fewest and simplest, and the technique easily acquired. The only thing that is not easily acquired is Mr. Blount's genius for pattern-making, which is, unfortunately, the important thing. Mr. Blount's work is seen at its best on the beams and lintels of his own house. But even when he works for other people he has still this curious predilection of the true craftsman, for making kitchen and nursery utensils—spoon-racks and salt-boxes, and cradles, and so on—he makes no drawing-room furniture—he works for the working people.

All these unorganised efforts at reform, such as Mr. Blount's and Mr. Barnsley's, serve, in fact, to show that any real revival of a national art and handicraft involves legislation; involves, especially, the better payment of the people who do the work of the world. I only wish to insist that something ought to be done; and I cannot do better than conclude by quoting to this effect so great an authority as Plato:—

"Such qualities" [viz., 'of a mind that is really well and nobly constituted in its moral character'] . . . . "enter largely into painting and all similar workmanship, into weaving and embroidery, into architecture, as well as the whole manufacture of utensils in general, ... for in all these things gracefulness or ungracefulness finds place. And the absence of grace, and rhythm, and harmony, is closely allied to an evil style and an evil character; whereas their presence is allied to, and expressive of, the opposite character, which is brave and sober-minded. . . . .

"Ought we not therefore to extend our superintendence to the professors of every craft, and forbid them to impress those signs of an evil nature, of dissoluteness, of meanness and of ungracefulness on any work of their hand; altogether interdicting such as cannot do otherwise from working in our city, that our guardians (aristocracy) may not be reared amongst images of vice, as upon unwholesome pastures, culling much every day by little and little from many places, and feeding upon it, until they insensibly accumulate a large mass of evil in their inmost souls? Ought we not on the contrary to seek our artists of another stamp, who by the power of genius can trace out the nature of the fair and the graceful, that our young men, dwelling as it were in a healthful region, may drink in good from every quarter, whence any emanation from noble works may strike upon their eye or their ear, like a gale wafting health from salubrious lands, and win them imperceptibly from their earliest childhood into resemblance, love, and harmony with the true beauty of reason."

DISCUSSION.

Mr. H. H. Statham heartily agreed with the author in all he had said about the manner in which craftsmanship had degenerated. Nowadays a man, instead of designing and carrying out the whole thing, was engaged in mechanically making only one portion of an article. He also agreed with the author in thinking that the introduction of so much machinery had done very much to ruin the artistic spirit in the work. He could not, however, agree in Mr. Green's theory that the workman was only to work for those of his own class, and that the art was killed if he made things for people in a higher station of life. That theory was contrary to all history, and while the author talked about art having been killed by the exaggeration of class distinction, the facts were all the other way. For the last 200 years they had been breaking down class distinctions. The author had referred to the Italian Renaissance; but who were the people, who made a great deal of the beautiful work then produced, making it for? They were making it for persons entirely above their station. It would be seen, if one looked at the autobiography of Cellini, that even he produced work to please princes and poets, and sold that work to them. He (Mr. Statham) did not see that it was a higher theory of art to make things only for one's own class. If a man wanted to make beautiful things he would put his best work into it, whoever he was making them for. The audience had been shown that evening, some earlier specimens of wood work made before the specialist tools appeared, and he quite agreed that such work was much more interesting, and that there was more of the mind of the worker in it, but some of that work, especially the Norwegian chair, looked to him a little clumsy. He could not see why there should not be good art combined with what one might call elegance and finish, such furniture as that of Chippendale and Sheraton, which he called furniture with a distinction about it. He could not understand

the passion for kitchen chairs and tables at the present time, he thought they might very well be kept for the kitchen. He himself preferred in his drawing-room fine and graceful furniture.

Mr. EDWARD SPENCER remarked that the author had lamented the incursion of an alien art into England at the time of the Renaissance, and had rightly attributed to that incursion the cessation of continuity in tradition, which was so important in the arts and in the crafts. Another effect of their incursion was the gradual severance of the functions of design and execution, which went to make what might be called the drawing-room art of the present day. But one could not help recognising the fact that at the time when the Renaissance art was brought into England from Italy, after travelling through France, westwards and northwards, the tradition as it existed then in England was not a very healthy one. Gothic art was in its decadence, and it was because of this decadence that it allowed the Renaissance, the classic, the foreign art to usurp its position. The reason that Gothic art was then in its decadence was, he thought, because those institutions which were designed to protect the crafts and the privileges of the craftsmen had themselves began to suffer from the shock of quite a new and antagonistic force—the force of capitalism. It was because it was so essential that in a modern State they should not only have fine crafts, but also institutions designed to protect the development of those crafts, that he should like to quote Mr. Hobson, who said in his book, "The Social Problem," that it was not enough to have a changed heart in the community in order to ensure reform, but it was necessary to have the forms—Mr Hobson meant the political forms—that fitted them. For that reason he (Mr. Spencer) endorsed the author's opinion, that the relationship between politics and art was a very close one.

Mr. A. ROMNEY GREEN, in reply to Mr Statham, said that theoretically, class distinctions were less now than in the Middle Ages, but, practically, they were greater; there was a social tie recognised between the upper and lower classes in the Middle Ages which was not recognised in the same way at the present time. With regard to Cellini he should say that his art was a fine art, and he (Mr. Green) had not been talking in his paper about fine arts—painting, sculpturing, and so on; Cellini would rank as a sculptor, not as a furniture maker. With reference to Mr. Statham's criticism of the eighteenth century furniture, he would point out that the makers then were, as a rule, their own designers; whereas in joinery, in making doors, and so on, the designing of such things was done by architects. That was the reason why the eighteenth century doors were decadent, but the furniture of that period was not.

On the motion of the CHAIRMAN, a hearty vote of thanks was accorded to Mr. Green for his paper.

THE RESOURCES OF SPITZBERGEN.

When the islands of Spitzbergen were first discovered by Dutch sailors in the year 1596 they were found to be without inhabitants, but abounding in game and fish. A station was built at Smeerenberg on the south-easterly coast of what is now known as Dane Island. Dutch whalers visited the islands in great numbers for a long time, and as time passed Russian, Norwegian, British, Swedish and Danish fishermen and hunters also found the remote region worth visiting. Of late years the Norwegians are the people who pay most attention to this field. In the year 1906 six different Norwegian whaling expeditions with crews aggregating 420 men, made their stations there. Besides these a great number of smaller craft from towns of northern Norway visit the islands every summer, hunting and fishing; some hunters also pass the winters there. The cargoes brought home consist principally of oils, furs, and eider down. The aggregate yearly outcome is estimated at about £100,000. A few years ago it was discovered that coal of fair quality appeared in various localities. Experimental mining has been conducted by several parties, and during the past winter no less than three well-established and equipped expeditions, aggregating more than 150 men, remained in the islands. In the largest of these a good deal of American capital has been invested. Game such as reindeer, polar bears, ptarmigan, geese, ducks and other birds are still fairly plentiful in the islands, but as no one is in control the fauna are being wantonly exterminated, being killed at all seasons of the year. One of the visitors there last summer reported that a party of tourists killed upwards of 100 reindeer, leaving the carcases where they fell, only bringing away with them a few of the finest heads and antlers for mounting. The eider duck is so tame while hatching that it may often be lifted by hand while the nest is robbed of down and eggs. In Norway stringent laws have been enacted for the protection of this valuable bird. It is stated on good authority that the walrus by this time is nearly extinct, the white whale which was formerly very abundant, is becoming scarce, the numbers of seals and polar bears are largely reduced, and that the reindeer and birds are being killed at all seasons and are becoming exterminated. No nation has yet taken possession. It would seem high time for the nations most directly interested to come to an understanding whereby the islands, including Bear Island, either were formally turned over for annexation to one certain power, or else that a combination of the powers would make arrangements whereby law and order could be maintained, game and fishery laws made and enforced, and mining claims protected. The prospect for paying coal mining is good, and the claim is made that indications of valuable minerals are present. Tourist steamers of different nationalities visit the islands every season. The warmest part of the year is the first half of August, when the thermometer sometimes reaches 60 degrees Fahrenheit.

HOME INDUSTRIES.

The Railway Companies and Wages.—There is no immediate likelihood of a strike of railway servants for higher wages, but the men are making preparations that suggest the probability of their pressing their demands before many months have passed. Reference was made in these notes last week to the agreement arrived at between the Engineering Employers' Federation and the Engineering Trade unions, and to the admirable example it sets to other trade organisations. But between the present position of workmen in the engineering and railway trades there is an important difference. The Engineering Employers' Federation recognise and treat with the unions, the railway directors do not, because there is no body sufficiently representative of the men to warrant the directors in assuming that it speaks for the great majority of them. A year ago the Amalgamated Society of Railway Servants consisted of 60,000 men, or only 28 per cent. of the total possible number of men in the grades represented by the society. It was not unnatural that railway directors should decline to admit that a society representing so small a percentage of the total body of the men was really representative. It is true that during the present year, owing to exceptional efforts, there has been a large increase in the membership, which has brought the proportion of the men who are members of the society to 38 per cent., and the membership is still increasing rapidly, so rapidly that if this increase continues for another few months the society will be in a position to claim that it speaks for the majority of the men. The railway servants enjoy some advantages over similar *employés* in other trades. Their employment is continuous, and they are as safe in it as a civil servant, whilst some of them receive pensions when too old to work, and many get tips which add materially to their wages. But as a body they have grievances, the principal of them perhaps being the question of hours. And here the public interest is very directly concerned. The question of Sunday labour is a branch of the same grievance and should not be incapable of satisfactory settlement.

Bankruptcy in 1907.—The number of bankruptcies may be taken as a rough index of the state of trade. According to this test trade is in a comparatively satisfactory condition. During the three months ended March 31 the total number of bankruptcies was 1,083, as compared with 1,254 in the corresponding month of 1906, and 1,317 for the three months ended March 31, 1905. The reduction is more noticeable in the High Court than in the County Court cases.

The Boot Industry.—The boot manufacturers are grumbling loudly at the continued high price of leather. They have not yet been able to obtain an adequate advance in prices, and they complain that their margin of profit has disappeared. The demand is for light boots. Even the working classes are discarding heavy footwear. But this demand for light boots makes matters worse for the manufacturers, as light leathers are the dearest and most difficult to obtain at anything like a reasonable rate. The demand for them comes not only from boot manufacturers, but also from glovers, the motor trade, bag and belt manufacturers, and others, and the supply is not equal to it. High-water mark was thought to have been reached at the Leeds leather fair, but since then small transactions have been recorded at higher rates. It was thought that prices would recede to something like their former level when the exceptional influences of recent years—the war, the famine in India, the disturbance in the Chicago stock yards—had ceased to operate, but the growing demand was underestimated, and instead of abundant stocks and falling prices leather is still scarce and dear. Supplies are increasing, but the demand increases more rapidly, and there seems little likelihood of any substantial fall in prices. None of the many substitutes for leather in the market can equal it in its hard-wearing and damp-resisting properties. The inventor who discovered such a substitute would be a public benefactor.

Insurance and the Cotton Industry.—The Federation of Master Cotton Spinners' Association has adopted a scheme for insuring "sprinkled" cotton mills against fire, and are considering another for the covering of risks under the new Workmen's Compensation Act, which comes into force on July 1. With two unimportant exceptions all the accident offices have now agreed upon a tariff which binds the several companies to minimum premium rates. In mule spinning the official rate is 15s. per £100 of wages paid, for ring spinning 4s. 6d., and for weaving 4s. 6d. Employers are dissatisfied with these rates, considering them excessive, and steps are, it is understood, being taken to make other arrangements of a special nature to cover the liability of cotton spinners under the Act.

Fast Colours.—A discussion in the *Manchester Guardian* on fast colours has led to an interesting letter from Mr. W. M'Farlane, of Miller's Brook, Heywood. "Fastness," as Mr. Heywood points out, is a relative term, no two colours being capable of withstanding the same test to exactly the same degree. This is why it is so difficult to formulate a test which shall satisfy all requirements. For commercial purposes colours must be tested according to the specific uses to which they are to be put. A colour satisfactorily "fast" for one purpose may be quite unsuitable for another. Fast colours in the laundry sense are colours that will stand washing and bleaching. Up to recent years the only colours of this class were turkey red and indigo blue, and even the latter was somewhat overrated, losing, as it does, the major part of its substance under

bleaching, and sometimes, unless the dyed shade be very dark, disappearing altogether. Now, thanks to the researches of colour chemists, it is possible to produce a quite extended range of shades which fulfil the present exacting requirements, and which really deserve the name of "fast" colours. This is especially the case with blue, which can be made not only much brighter but infinitely faster to bleaching materials and lighter than the old indigo. The skilled dyer now produces "fancy" shades of equally stable character, and practically as durable, as the fabric into which they are woven.

British Insurance and San Francisco.—In referring to the great fire in San Francisco, Mr. Consul-General Bennett says that amongst the defaulting companies there does not appear the name of a single British corporation. From a return made by the insurance companies, it appears that the amount of insurance written in San Francisco in 1905 by 92 companies was very nearly 756,000,000 dols., whereas the amount written in 1906 was 890,000,000 dols. The premiums taken by companies, American and foreign, which maintain their reputation for honourable dealing in the recent disaster, have increased largely. The Consul-General puts the general average at practically 50 per cent., but one English company has increased the amount of premiums taken in the past year from 300,000 dols. to over 800,000 dols., whilst another has increased from 300,000 dols. to over 600,000 dols. This business is now distributed not amongst 223 companies, as was the case in 1906, but amongst 92. "It is gratifying to notice," writes the Consul-General, "that with very few exceptions, and those owing to complications caused by the earthquake clause and its doubtful interpretation, the English companies have fully maintained their reputation for prompt settlement of losses, and that they are now reaping a rich harvest in new insurance work in San Francisco, at considerably higher premiums than were charged before the fire."

The Wheat Harvest Outlook.—There would seem to be some ground for the recent advance in the price of wheat, and the belief that the world's wheat harvest will be a short one. In the United Kingdom the plant looks well in most districts, but, unfortunately, nowadays the home output is too small to have much effect upon prices. Elsewhere—in the countries from which the United Kingdom obtains the larger part of her wheat supplies—the present outlook is disturbing. In the United States, according to the Washington Bureau, 3,500,000 acres of winter wheat have been "winter killed," and it is expected that the winter wheat crop will be about 100,000,000 bushels less than last year, whilst the condition of the spring wheat is described as very unfavourable in North Dakota and North Minnesota, consequent upon the extremely late season. The reports from Canada are not more favourable. In Manitoba and the Canadian North-West spring sowings had hardly commenced on May 1st owing to the inclemency of the weather, and a late season spring wheat crop seldom gives a heavy yield in those districts. The strange character of the weather during the past winter seems to have been general not only in America but in Europe. In Russia, from which so much of the wheat consumed in the United Kingdom is got in these days, semi-official reports put the damage to autumn wheat in the districts where it is mostly grown at from 5 per cent. to 50 per cent. The Spring wheat crop was sown late, and owing to the unfavourable weather the condition of the crop is precarious. In Roumania the official reports speak of a loss of 25 per cent., and unofficial estimates put the 1907 crop at 50 per cent. less than that of 1906, when the wheat crop yielded 13,600,000 quarters. In Austria-Hungary, the Argentine, Australasia, and India, crops promise average yields, but nowhere is there a surplus. Of course, the weather of the coming months may materially alter the present outlook, but probabilities point to a considerable shortage in the world's wheat crop in 1907, and, so far as the United Kingdom is concerned, the supplies are believed to be much smaller than usual.

The Income Tax and Cotton Spinners.—The Federation of Master Cotton Spinners' Association object to the proposed new regulations relating to income tax assessments, more especially to the abolition of the three years' average clause so far as it affects cotton mills. Cotton spinners also contend that it would be unsatisfactory to them to have assessments made by the Surveyor of Taxes instead of the Income Tax Commissioners.

OBITUARY.

SIR BENJAMIN BAKER, K.C.B., K.C.M.G., F.R.S.—The Society has suffered a serious loss by the death of Sir Benjamin Baker, one of its Vice-Presidents, who died suddenly at Pangbourne on the 19th inst. Sir Benjamin was elected a Member of the Society in 1884, and became a member of the Council in 1888. In 1900 he was elected a Vice-President, and held the office till 1903. He was again elected in 1906, and remained a Vice-President until his death. In February, 1889, he read a paper on the "Forth Bridge," and several times took the chair at meetings of the Society, the last occasion being at the reading of Major Baden-Powell's paper on "Aerial Navigation" on the 17th of April last.

Sir Benjamin had achieved a great reputation as an engineer, and at the time of his death was certainly regarded as the head of the profession in this country.

The work which made his reputation as an engineer was the Forth Bridge, in which he was associated with Sir John Fowler, at that time his senior partner. This and the Barrage of the Nile will always be considered his most important works, though there are besides these many which would have sufficed to make a reputation for a smaller man. His engineering labours were recognised by the grant, first of the K.C.M.G. and then of the K.C.B. In 1895 he served as President of the Institution of Civil Engineers, and in 1890 he was elected a Fellow of the Royal Society. He was in his 67th year at the time of his death.

GENERAL NOTES.

CHANGES IN ROME.—Within the last 37 years Rome has been almost rebuilt. A map of 1870 compared with one of the present time will show that its topography has altered considerably. Strenuous efforts are being made to establish manufactures. The possible harnessing of a portion of the Tiber, and of the waterfalls near Rome, as a motive power, the recent 50 per cent. reduction on the important duty on petrol, the proposed reorganisation of the electric supply service, and other reforms of a wide public character are expected to assist to this end. In his report upon the trade of Rome in 1906 (Cd. 3283) Mr. Consul Morgan says that complaints that Rome has been spoilt by the obliteration of some of the traces of the past are not, in his opinion, well founded. "All that could be preserved of the past of Rome was most scrupulously saved, and even now important schemes are under official consideration for the protection of the city's monuments." Mr. Morgan says that Rome is gradually becoming an important market for the sale of works of art. Visitors give extensive orders for copies of old masters existing in the Vatican galleries as well as the Capitoline museums, or belonging to private collectors. The exportation of old works of art is checked on account of the Government restrictions, which are getting every year more stringent, local public opinion being decidedly against the exodus of what is looked upon as the national artistic patrimony.

MEETINGS OF THE SOCIETY.

INDIAN SECTION.

Thursday afternoon, at 4.30 o'clock:—

MAY 30.—"Irrigation Colonies in India." By LAURENCE ROBERTSON, I.C.S. CHARLES EDWARD HENRY HOBHOUSE, M.P., Under Secretary of State for India will preside.

APPLIED ART SECTION.

Tuesday evening, at 8 o'clock:—

MAY 28.—"Sheffield Plate and Electro-plate." By SHERARD COWPER-COLES. SIR JOHN EDWARD BINGHAM, Bart., will preside.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 27...Geographical, University of London, Burlington-gardens, W., 3 p.m. Annual Meeting.

British Architects, 9, Conduit-street, W., 8 p.m.

Medical, 11, Chandos-street, W., 8½ p.m. Annual Oration.

Victoria Institute, 8, Adelphi-terrace, W.C., 4½ p.m. Rev. F. Stores Turner, "Mencius."

TUESDAY, MAY 28...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Applied Art Section.) Mr. Sherard Cowper-Coles, "Sheffield Plate and Electro-plate."

Faraday Society, in the Library of the Institution of Electrical Engineers, 92, Victoria-street, S.W., 7.50 p.m. Annual General Meeting. 8¼ p.m. 1. Mr. F. H. Campbell, "Contributions to the Chemistry of Gold." 2. Dr. F. Mollwo Perkin, "Reduction of Oxides, Sulphides, &c., by Means of Metallic Calcium." 3. Dr. T. M. Lowry will Exhibit Thermostatic Apparatus.

Royal Institution, Albemarle-street, W., 3 p.m. Professor G. H. Nuttall, "Malaria, Sleeping Sickness, Tick Fever, and Allied Diseases." (Lecture I.)

Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m.

Statistical, 9, Adelphi-terrace, W.C. 5 p.m.

Photographic, 66, Russell-square, W.C., 8 p.m. Messrs. C. E. Kenneth Mees and J. K. Baker, "Measurement of the Efficiency of Dark-room Filters."

Zoological, 3, Hanover-square, W., 8½ p.m.

Horticultural, Vincent-square, Westminster, S.W., Annual Flower Show in Temple-gardens, E.C.

WEDNESDAY, MAY 29...British Astronomical, Sion College, Victoria-embankment, E.C., 5 p.m.

Colonial Institute, Whitehall Rooms, Whitehall-place, S.W., 4½ p.m. Mr. J. Burtt-Davy, "Agricultural Possibilities in the Transvaal."

THURSDAY, MAY 30...SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Indian Section.) Mr. Laurence Robertson, "Irrigation Colonies in India."

Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Prof. Sir James Dewar, "Chemical Progress—Work of Berthelot, Mendeleeff, and Moissan." (Lecture II.)

FRIDAY, MAY 31...Royal Institution, Albemarle-street, W., 9 p.m. Mr. A. H. Savage Landor, "Recent Journey across Africa."

SATURDAY, JUNE 1...Royal Institution, Albemarle-street, W., 3 p.m. Sir William White, "The Contest between Guns and Armour." (Lecture I.)

Journal of the Society of Arts.

No. 2,845. VOL. LV.

FRIDAY, MAY 31, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

ALBERT MEDAL.

The Council of the Society, with the approval of His Royal Highness the President, the Prince of Wales, have awarded the Albert Medal for the current year to the Earl of Cromer, O.M., G.C.B., G.C.M.G., K.C.S.I., "In recognition of his preëminent public services in Egypt, where he has imparted security to the relations of this country with the East, has established justice, restored order and prosperity, and, by the initiation of great works, has opened up new fields for enterprise."

CONVERSAZIONE.

The Society's Conversazione will be held, by arrangement with the Council of the Royal Botanic Society, in the gardens of that Society, Inner Circle, Regent's-park, on Tuesday evening, July 9th, from 9 to 12 p.m.

The central portion of the gardens only will be used. The Conservatory and the Club-house will be open.

The reception, by Sir Steuart Colvin Bayley, K.C.S.I., C.I.E., Chairman, and the other members of the Council, will be held at the entrance to the Conservatory, near the Broad-walk, from 9 to 10 p.m.

Each member is entitled to a card for himself (which will not be transferable) and a card for a lady. In addition to this, a limited number of tickets will be sold to members of the Society, or to persons introduced by a member, at the price of 5s. each, if purchased before the day of the conversazione. On that date the price will be raised to 7s. 6d.

Members can purchase these additional tickets by personal application, or by letter addressed to the Secretary at the offices of the Society, John-street, Adelphi, W.C. In all cases of application by letter a remittance must be enclosed. Each ticket will admit one person, either lady or gentleman, and must be signed by the member applying for it.

Tickets will only be supplied to non-members of the Society on presentation of a letter of introduction from a member.

A programme of the arrangements for the evening will be published in due course.

PRIZES FOR INDUSTRIAL DESIGN.

The Council of the Society of Arts hold a sum of £400, the balance of the subscriptions to the Owen Jones Memorial Fund, presented to them by the Memorial Committee, on condition of their spending the interest thereof in prizes to "Students of the Schools of Art who, in annual competition, produce the best designs for Household Furniture, Carpets, Wall-papers, and Hangings, Damasks, Chintzes, &c., regulated by the principles laid down by Owen Jones."

The prizes will be awarded on the results of the annual competition of the Board of Education, South Kensington. Competing designs must be marked, "In competition for the Owen Jones Prizes."

No candidate who has gained one of the above prizes can again take part in the competition.

The next award will be made in 1908, when six prizes are offered for competition, each prize to consist of a bound copy of Owen Jones's "Principles of Design," and the Society's Bronze Medal.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

Thursday afternoon, May 2, 4.30 p.m.; SIR CHARLES A. ELLIOTT, K.C.S.I., LL D., in the chair.

The CHAIRMAN, in introducing the reader of the paper, said that Sir Edward Buck occupied an eminent position in all matters concerning agriculture and irrigation. He (the Chairman) first became acquainted with him more than forty years ago, when he was in charge of the Cawnpore Model Farm, which was one of the first institutions established to enable English officials to obtain information about native methods of cultivation before they tried any reforms or improvements of their own. After that he was associated with the author in the settlement of the Farukhabad district, where they studied together the work of the canal system, the fertilising power of its waters on the crops, the injury done by the water if efficient means were not provided to carry it off again, and the remarkable effect it produced by liberating the labour of thousands of men and cattle from the drudgery of drawing water from the wells and distributing it in a minute trickle over the fields. Afterwards, when Sir Edward became Director of Agriculture, he took up a number of interesting projects, such as the producing of silk in Dehra Dun and the growth and manufacture of tobacco in Ghazipur and Pusa. His greatest achievement of all was his standardisation of the system of cadastral survey, and the creation of a permanent record of rights, automatically corrected year by year by the village accountants. Since he resigned the service he had not lost his interest in India, having revisited it every year to keep himself abreast of all that was going on in the way of progress and reform; and now he came before the Society to offer a most valuable contribution to their general knowledge by showing what Italy had to teach India in the use and control of water.

The paper read was—

THE APPLICABILITY TO INDIA OF THE ITALIAN METHOD OF UTILIZING SILT.

By SIR EDWARD CHARLES BUCK, K.C.S.I., LL.D.

On the 7th of June, 1904, an agricultural conference held at Ravenna in North Italy passed the following resolution: "That whereever fertilizing silt is available it is a grave economical error not to profit by it." I ask you to accept this resolution as the text of my address.

I have had some hesitation in deciding whether to begin by talking about India or about Italy. Perhaps the simplest plan will be first to indicate briefly what India has done to utilize silt, then to describe what Italy has done, and finally to suggest the further possibilities in India.

Let me first explain how my own attention was drawn to the subject. Sometime after the first Provincial Department of Agriculture in the Upper Provinces was committed to my charge, I visited an estate managed by an English planter on the banks of the Ganges, who, among other improvements, had controlled the drainage on the summit of the cliffs, and by a system of small dams across the gullies, supplemented by terracing, checked the further erosion of the uplands; held up the silt carried by the drainage, and quadrupled the letting value of the land.

Returning with this object-lesson in my pocket to the provincial farm near Cawnpore, I took in hand a small area of broken, raviny, and mostly unculturable land close by, and began "doctoring" it with dams and drains much in the fashion of a boy playing with sand on a seaside beach, but was removed from the province before I had seen more than the commencement of the slow process of silt deposit. An intelligent native assistant, however, had watched and appreciated the proceedings, and carrying them on after my departure eventually asked for and received permission to rent from the proprietors the broken and neglected lands of the neighbourhood, which he succeeded in transforming into a profitable estate, of which the rental has been more than quadrupled. He is still, in 1907, extending further afield the system which has made him, after retirement, a prosperous farmer. As long ago as 1892 my successor, Mr. Holderness, wrote to him as follows: "You have clearly shown that by embankment and a very moderate outlay on manure it is easily possible to improve broken and apparently sterile land and convert it into fertile fields. Until I saw your work I had not realised how valuable the simple expedient of embankment is."

Later on, I came across in Gwalior, a State as large as Ireland, an interesting illustration of the value of silt. There Colonel Pitcher, once my assistant, then the administrative factotum of the Maharaja, had enclosed the catch basins of large areas by low banks sometimes a mile or two in length, which focussed the drainage towards a strong

dam, so as to form a small lake from which the rice fields *below* the dam were irrigated. When the water was drained off at the beginning of the winter, it was found that the silt deposited *above* the dam gave magnificent crops of wheat, and this notwithstanding the fact that the drainage had been drawn from the poorest of soil, and from stoney hills in which only low scattered scrub could grow.

In my further tours through India I ascertained that in many localities the advantage of capturing and utilizing silt was appreciated by cultivators, who did their best to secure it on a very petty scale, but I did not find that any important attempt had been made in the same direction by the authorities.

What I had seen and heard led me in 1893 to obtain permission to issue a circular to all provinces asking for the facts. The opportunity was taken to circulate an extract from Scott Moncrieff's "Irrigation in Europe," in which he described, to use his own words, "the enrichment of a barren and worthless valley in the Moselle country by no manure save the alluvial matter deposited by abundant irrigation," and the question was asked whether anything of the sort had been done in any Indian province.

The replies were received just as I was leaving India. I have them here, and they are of great interest. They indicate

1. That in many localities cultivators appreciate the value of silt.
2. That, with or without financial assistance, they take action of a petty character to secure it.
3. That action is mainly confined either to the damming or terracing of broken land, or to the swamping of rice lands with silt-laden water.
4. That in a great part of India no practice of any kind prevails.
5. That nowhere, with very few exceptions, have the authorities themselves undertaken any important scheme.

There is no time to go through the replies province by province, but I may quote the first (that from Madras) as a sample :—

"Except in four districts," it was written, "no action has been taken of late years to promote the construction of dams or for fertilizing by silt deposit. There is little or no information regarding the practice of ryots, but they are in the habit of making small dams for preventing erosion, or in rice fields to bank in water for the deposit of silt."

In other provinces whatever encouragement is given to cultivators is for petty works of similar character.

We are told, too, of the reclamation of salt-lands on the Bombay coast; of the flooding of some lands on the Indus; of the terracing of small tracts below the salt range; and of the silting up of a few depressions by canal officers in the Punjab, in all of which operations the authorities have interested themselves. But these cover but an insignificant area compared with that of India. We are told, on the other hand, by the Agricultural Department of Upper India, that in 13 sub-Himalayan districts, say 30,000 square miles, where it is written the system described by Scott Moncrieff, might well be carried out, nothing has been done either by the cultivators or by the authorities to arrest the silt.

Such was the position in 1895. It has hardly been affected by anything that has been done since, except, perhaps, in Bombay, where the damming of ravines and gullies has been encouraged as a famine relief work.

My own attention was not again drawn to the subject until June, 1905, when I had the honour to represent the Government of India at the Agricultural Conference at Rome. This gave me the opportunity not only of learning something of what had been done in Italy in the way of capturing silt, and of receiving invitations, private and official, to come and see how it was done, but also that of discussing the subject with Lord Minto, who led the British representatives at the Conference. I did not then know that I was talking to the future Viceroy of India, but the circumstance led, perhaps, to the mission with which Lord Minto's Government charged me in 1906 to visit Italy and to submit a report on their methods. I may indeed say that but for Lord Minto's interest in the subject I should not be addressing you this evening.

I will now ask you to follow me to Italy, and learn with me something of the great work—viz., the control and utilization of drainage streams and rivers—which has been carried on in that country for centuries, but never with so much energy and so effectually as at the present time.

I may at once say that I met with the most cordial reception at the Ministries of Public Works and of Agriculture; that I was made acquainted with all official and other literature on the subject; that I was given introductions to the engineers on the principal works which I wished to visit, as well as to the agricultural and chemical professors at the Universities;

that the engineers themselves gave me the fullest assistance and instruction; and that the University professors provided me with much useful information.

From no one did I receive greater kindness than from Count Pasolini, whose grandfather, the great statesman and an equally great agriculturist, was an intimate friend of Lord Minto's grandfather, with whom he stayed in Scotland. Count Pasolini volunteered to take me to Ravenna, where he is continuing the work of his grandfather in improving his large estates, as are other proprietors in the neighbourhood, by overlaying the lower lands with a deep deposit of river silt. I will not attempt to describe my tour except to say that the most important works which I visited were those at Ravenna, conducted by landowners, and those at Capua and at Grosseto, conducted by the Government, as well as many in which operations had been completed. I have only time to give you a general—bird's-eye—view of what has been, and is being done in Italy.

History shows that in the utilization of the waters of their rivers for various useful purposes the Italians have long given lessons to the world. For some centuries past they have taken the utmost pains, quoting their own phrase, "to put the bridle on" one after another of their streams. It was at the end of the twelfth century that, following the lead of their Roman ancestors, they began to turn their rivers into canals, of which the objects were to carry irrigation to the agricultural lands and potable waters to the towns. Two of the most important of such works in operation at the present day were constructed not less than seven hundred years ago. But the supply of irrigation and pure drinking water were not the only objects for which they harnessed their streams for, as time went on, they found that they could, to quote one of their writers, "use the waters of a river as a weapon of defence against the destructive and pernicious influences of the very river itself." Leonardo da Vinci, whose genius as an engineer was even more remarkable than his skill as a painter, had been among the first to point the way. The heading of the fifty-third chapter of his great treatise on the "Movement and Measurement of Waters" is "How with the running waters we ought to carry the earth of the mountains into the valleys, so as to render them fertile, and to purify the air." And for the last five centuries the intelligence of the Italian engineers has been directed to forcing each stream to turn the swamps which it had itself caused into fertile plains, and to build up with its own silt rich terraces in the very ravines which it had torn from the hillsides.

It is interesting to learn from Italy to how many useful purposes the drainage of a country can be directed when once it has been brought under control.

There is an extensive Italian literature on the subject, but the most recent and comprehensive works are two published as lately as 1902 and 1904, by Engineer Niccoli, Professor of Agricultural Chemistry at the Pisa University. Omitting domestic uses and the like his divisions of the agricultural uses of controlled water are:—

1. Irrigation, or the supply of water to crops.
2. Fertilization of land by irrigation.
3. Fertilization of land by submersion.
4. Protection against frost by submersion.
5. *Bonificazione* in the plains.
6. *Bonificazione* in the hills.

I will deal as quickly as I can with the first four on the list, for it is to the last two, Bonificazione in the plains and hills, to which I wish to draw attention. But I must explain the meaning of Bonificazione. (It is to me a more blessed word than Mesopotamia.) I can, however, suggest no one English word as its equivalent. In paraphrase it means in the plains the fertilization and sanitation of low-lying unhealthy lands by deposit of silt combined with drainage; it means in the hills the utilization of silt and the prevention of erosion.

Returning now to Professor Niccoli's list:—First, irrigation of crops—well, we know all about that in India. In no country has a more splendid work been accomplished than that of our engineers, second to none in the world, in the bridling of the great northern rivers and in using their captured waters for the irrigation of crops. But it is interesting to remember that they, too, carried to India an object-lesson from Italy. Three of the leading pioneers of our Indian canal system, Cautley, Baird Smith, and Scott-Moncrieff—great names—travelled through Southern Europe to study the irrigation works and methods of France, Spain, and Italy, learning lessons, specially from Italy, which have been applied not only to India, but in later years also to Egypt.

The next subject is the *fertilization of land by irrigation*. This can only be done when the water contains fertilizing material. The pro-

cess is, in a sense, silt depositing, but it is only a veneer of silt, and can be applied to land either prepared for or bearing crops. The extension of the practice is strongly urged by the agricultural authorities. Thus writes a professor of the Pisa University, in his advocacy of the practice:—"The silt of the river Arno contains, weight for weight, as much fertilizing substance as would be obtained from half the amount of stable manure, and can be easily utilized for irrigating cultivated land."

The third subject is *fertilization of land by submersion*. This process, as in India, is chiefly applied to rice lands. But Professor Niccoli goes further, and shows with the aid of diagrams a plan on which it is carried out on gradually descending levels, systematically arranged for the purpose. He refers also to the Nile system, which includes fertilization of land both by submersion and by irrigation. And I have received, from Sir Thomas Elliott, a note courteously prepared for me by Mr. Sabin, of the Board of Agriculture, showing that the practice has, under the name of "water meadows," prevailed in some parts of England where the value of the land has often been increased tenfold by the process. It is interesting too to learn that Arthur Young, the father of agricultural reform in England, introduced a method not unlike the "gradually descending" plan of Professor Niccoli; and that later on an improved system was advocated by, among others, a former Secretary of State for India, Sir Stafford Northcote, who gave a description of it, as long ago as 1852, in the "Journal of the Royal Agricultural Society." The area of water meadows in England is said to be about 100,000 acres.

The system of "warping," which implies the spreading of fertilizing water on the deltas of rivers when the incoming sea tide turns back the river flow, is also described by Mr. Sabin, as practised on the Humber and elsewhere, and I can only regret that the time allotted to me does not permit me to give further details of either water meadows or warping.

I must deal quickly too with the next subject, *Protection against frost by submersion*. All of you who have travelled through Lombardy in the winter, must have seen on either side of the train what appears to be a serious inundation extending as far as the eye can see. These are the so-called "*marcite*" meadows in which grass and other herbage is protected by water, innocent as I found, of silt. The sole object of the flooding is protection from frost. Even in India the market gardeners hurriedly run water over fields occupied by valuable crops when frost is expected. And with reason. For in view of the fact that the vapour of water is known to be more impermeable to heat than almost any known substance, it can readily be understood that a stratum of moisture temporarily raised over the crop prevents heat from escaping from the soil.

We now come to the main subject of our discourse, *Bonificazione in the plains*. The blessed word includes on one hand the drainage of water-logged tracts and on the other hand the building up (*colmata*) of low-lying lands by river silt. These are the two measures with which the Italians have sucessfully banished malaria from some thousands of square miles of their country. To anyone to whom the knowledge of the facts is brought for the first time both the magnitude of the work and the patience with which it has been and is being executed must be the cause of surprise and admiration.

A splendid reward has been reaped. For Bonificazione now directed primarily against malaria at the same time confers upon the land such exceptional fertility that tracts in which man could hardly live or gain a livelihood are to-day crowded by a prosperous peasantry.

The history of Bonificazione is a long one. It began with the drainage of marshes by the Romans. But no comprehensive schemes were undertaken until the twelfth century, when measures were commenced for the amelioration of the historical "Val di Chiana," supplemented later on by the treatment of some hundreds of square miles in other localities, notably between Pisa and Florence. It is interesting to know that the first to study the question of silt deposit to which the reclamation of the Val di Chiana is due was Torricelli, a pupil of Galileo. The valley comprises about 800 square miles, of which no less than 500 have been built up by silt, but it was not until the end of the eighteenth century that it was authoritatively announced that malaria had been finally expelled from the valley. "All the transformations have been due," says the official report, "to the natural deposit of silt spread over the land by branch streams directed more or less by man."

In an interesting report of 1903, the first of a series under issue by the Italian Parliament, the history is commenced of the whole series of Bonifcazione works now in progress. It is

prefaced by a brief but instructive account of the running fight against malaria during recent centuries. This shows that a careful study made long ago of the conditions under which malaria prevailed proved emphatically that they were the very conditions which medical discoveries have since established as necessary for the existence of the mosquito. But the cause not being then recognised, popular and medical prejudice strenuously opposed the piling up of river silt, the decaying matters in which were, it was contended, a dangerous source of the malady. Nevertheless, the State engineers persevered and later medical science has proved them to be right. "Now," writes the author of the report, "the new school of medicine welcomes Bonificazione, of which silt deposit is the main feature, as the sovereign remedy (*remedio sovrano*), at the same time that it is financially beneficial."

We may pass now from the centuries preceding to the period succeeding the Unification of Italy in 1862. Although in the first few years political interruptions interfered with progress, yet by degrees a comprehensive scheme was launched for gradual Bonificazione throughout the whole of Italy. I will not attempt to follow the changes in legislation which experience showed from time to time to be necessary for the object in view, but will commence with the latest Act of 1900. This Act confers upon the State the right of undertaking the Bonificazione of all unhealthy lands, whether private or public, the exercise of the right being justified, states the Act, by the necessity (1) of lessening the difficulties of police supervision; (2) of removing the causes of malaria. The first object is explained by the fact that bandits and criminals have been in the habit of taking refuge in malarial swamps where the police are afraid to follow them. So it is in the malarial Terai of North India.

To return to the Act. Bonificazione is divided into two so-called "categories." The first category includes important works of drainage and silt building conducted by the *Government*. The second category, those in which private interest is (*a*) dominant, (*b*) exclusive. These are conducted by *private agency*.

Expenditure on works of the first category is divided in the following proportions. The State pays 6-10th, the province 1-10th, the commune 1-10th, and the proprietor 2-10th. In the (*a*) class of the second category, if any hygienic result at all can be proved, the State may award 1-10th, and the province and commune each 1-10th as a grant in aid. In the (*b*) class province and commune are not precluded from assisting. The enhanced value (*plus valenza*) of the improved land accrues to the proprietors, subject only to the ordinary land tax in all cases.

We may now pass to some very interesting figures, which indicate the magnitude of the campaign against malaria. In the last 42 years expenditure has been 221,000,000 of lire, or £9,000,000 sterling.

In 1903 the area then under treatment by Government agency is recorded as 4,300 square miles, of which 1,800 square miles has been finished, and 2,500 square miles are under execution.

The map exhibited shows the position and area of each work in progress. It will be noted that they are distributed over every part of Italy.

These figures do not include the work done before the unification, such as the Val di Chiana. There is no record of that area, but I believe that 3,000 square miles would be below the mark. Nor do they include the numerous works of the second category, such as the Ravenna estates. The area of these is not known, and I can only state that private owners are now so satisfied with the financial advantages of the silt system, that the practice is widely spreading. And it must be understood that even the works of the first category are not to be limited to the above record. As engineers are released from one scheme they will be put on a new one not yet included in the schedule. I was officially informed that unrecorded projects for Sardinia alone, involving mainly silt deposit, will take in about three-quarters of the island. A low estimate of the area, past, present, and future, might be 10,000 square miles, or about 1-10th of the area of Italy.

The question will be asked, What is the commercial aspect of Bonificazione? The answer is that all writers, early and late, testify to the profitable results of the *colmata* profits, of course varying with local conditions and the character of the silt. In one tract of 100 square miles which I visited, the benefit was made out to be 20 per cent., while in another district returns of private enterprise carefully examined by a Commission, showed it to be, as a rule, something like 25 per cent. Instances occur of enormous profit, such as an estate formerly worth 700 francs, selling for 50,000; but such exceptional cases are no guide. It is true that some of the older works, handicapped by

political interruptions, by inexperience, and by injudicious financial arrangements, resulted in loss. But, as the engineers all told me, "If they had known then what we know now, there would have been no loss." All round financial advantage may perhaps be safely estimated at 20 per cent.

I am referring here to the *colmata* or silt-built land, not to drained land, which is much less remunerative. In recent years a tendency has prevailed to lower the level of the water rather than to raise the level of the soil, because, say the engineers, and with reason, we can expel malaria far more quickly by drainage than by silt. But this view has put the agriculturists up in arms, and a somewhat acute controversy has been recently proceeding between them and the men of the public works which may be said to have been more or less concluded at that Ravenna Conference of 1904 by a resolution of compromise, which, while admitting the hygienic advantage of rapid draining, urged that where possible drainage should always be followed by deposit of silt because, and here came our text, *it was a grave error not to profit by fertilizing silt whenever it was available*. The Conference concluded by advocating the formation, as in Germany and in France, of a corps of agricultural engineers whose training and sympathies would promote agricultural as well as purely engineering interests.

I should detain you too long if I were to attempt to describe in detail the process and methods of silt building. Broadly speaking, the captured rivers or their canals are led into embanked enclosures, each of which may be a few square yards or a few square miles in area, on which silt-bearing water is allowed to lie until its silt has been deposited. The pen of an engineer is required for a further description, and more than 50 pages are devoted to the subject in one of Professor Niccoli's treatises. Many factors have to be considered; the slope of the ground; the character of the silt; the depth of the required deposit; the drainage system of the locality, and so on.

Much, as I have said, depends on the amount and value of the silt which the river carries. Very careful analyses are accordingly made by chemical experts of the silt taken from the river when in flood at various depths, and various distances from the banks. From some rivers, as at Ravenna, the silt is only worth taking immediately after heavy rains in the hills, which perhaps only occur six or seven times in the year, and even then the deposit of silt is confined to a few hours on each occasion. The river Volturno, on the other hand, near Capua, is much richer, and can be utilised more often and for longer periods. Progress in the former case is slower than in the latter.

A few words now about "Bonificazione in the hills." The system of reclaiming ravines and rugged hills is known as *colmata di monte*, or building up of the hills. This is carried out by private owners, not by the State, who cannot in this case plead the hygienic object. A long history is attached to the gradual development of the system. The earliest plan was the primitive practice of terracing, such as we are familiar with in the Himalayas, and, indeed, in mountainous regions throughout the world. But this method affords little protection against the gradual erosion of soil torn away into gullies by heavy rains and torrents. Here, again, Leonardo da Vinci was first with his advice, thus worded: "to break the ravine torrents by watercourses branching in various directions." Gradual modifications, which it is needless to describe, were made during succeeding centuries, until about 100 years ago, when in the hills between Pisa and Florence, the land agent, Testaferrata by name, of the Marquis Ridolfi, worked out a system described by one writer as a "stupenda invenzione," and which is now accepted both as fulfilling da Vinci's precepts and as the most perfect plan of dealing with gullies and rugged hills yet devised.

The following description was given of the system in my report to the Government of India:—

"The 'Testaferrata' system is described in a treatise by the grandson who has succeeded to the Rudolfi marquisate; also by Professor Niccoli, who devotes 40 pages to the subject; and more elaborately still by an agricultural professor, Conti; in each case with the aid of exp'anatory diagrams, wi hout which indeed it is difficult to give a clear account of the methods employed.*

"The following general remarks taken with little modification from Niccoli's 'Agricultural Uses of Water' may be useful:—

'The buildings up of the hill (*colmate di m nte*) have for their complex object the utilization of the force of the waters for the removal of the objectionable ruggedness, whether convex or concave, and for modifying or making more uniform the slopes. The waters act in a twofold manner—(1) by eroding the projections and convexities and carrying away earth

* M. Conti, "La sistema e lo scuolo delle acquè dei terrini di collina" (Casale, 1903).

from them; (2) by transporting and spreading the silt into depressions and concavities. The hills which lend themselves most readily to the system are those with rounded summits which supply a sufficient amount of rain water to the ravines. . . . . The first thing to do in order to prevent disastrous erosion is to surround the upper portion of the hill or slope with a trench succeeded lower down by similar horizontal trenches from which streams are conducted in any required direction. This is in effect the principal preached by Leonardo da Vinci in the chapter quoted in paragraph 1 of this report.' Professor Niccoli then enters into technical calculations which show that in a hectar of land ($2\frac{1}{2}$ acres) with a slope of 150 feet, 30 inches of rain in the year will give a force equal to one horse-power working 150 days in the year. 'The object is,' he adds, 'to use this natural force, by guiding and directing it, for levelling the ruggedness of the hill.'

"The preliminary treatment of the hill above indicated is then supplemented by what we may call the 'doctoring' of the ravines and by protecting the base of the slopes. For the latter purpose a large trench is carried round the foot of the slopes. Next dams are carried across the ravines above the horizontal trenches and gradually raised as time goes on. The framework is thus arranged in a manner which gives control over the drainage. Finally, small channels are led diagonally at steep inclination from the upper horizontal trench to the ravine hollows behind each dam. When rain falls, water, laden with soil, is carried diagonally into the hollow above each dam and allowed, when clear, to issue on the other side. Here the issuing stream is joined by the diagonal earth-laden feeder from the ditch above, and the waters of the two joining together are carried into the hollow above the next lower dam. The issue is made, after deposit of silt, from the opposite side, and thus the drainage, of which the torrential force is broken, is carried in a zigzag fashion, with halts behind each dam, to the main trench at the foot of the declivity.

"If there should be uneven land more horizontal in character at the base of the slopes, it may be levelled by silt deposited by the drainage, now completely under command, on a system similar to that adopted ordinarily in the plains."

I have now spent all the time I dare in demonstrating the great and patient work which, guided by its best intellects, has been accomplished by Italy, and I think you will all agree that in that magnificent work Italy has afforded a grand object-lesson to the world. I will endeavour now to suggest, though but imperfectly, the possible application of the lesson to India.

Going back to our text: "It is a grave error not to profit by fertile silt wherever it is available." It is doubtful whether in any country the adoption of the text and its application is more needed than in India. The crying want of agricultural India is manure. Admitting that water is its first need, and this is only true of some regions, we know that everything possible is being done by the State to satisfy that need. But water alone does not suffice. It has, indeed, been proved that pure water tends to impoverish land which is not refreshed by adequate manure.

The three most valuable manures which are in the West employed for the fertilization of land are in the East either exported or burned. These are bones, oilcake, and farmyard manure. The first two are exported, the last is, except in the rainy season, dried and burned as fuel. Imported and artificial manures are too costly for the ryot. It is difficult to see what other manure supply is available to India except the fertile silt of its rivers, streams, and drainage. If so it follows as a corollary that the drainage, streams, and rivers must be so bridled and controlled as to make them yield to the land as much as is economically possible of the fertile silt which they carry.

This is just what has been done in Italy. If India could do likewise, on the same scale, what would be the result? In Italy we have an area of, very roughly, 100,000 square miles; in British India an area, very roughly again, of one million square miles. We have assumed that the bonificated area of Italy will sooner or later be 10,000 square miles, or 1-10th of the whole country; allow one-half for silt deposit, and that will mean 5,000 square miles, or 1-20th of the whole area as built up by silt (*colmata*). This is well under the mark, especially if the agriculturists have their way in the future. Applying the fraction 1-20th to India, we should have 50,000 square miles of silt deposit.

It may be said, it has been said, that India does not lend itself so well as Italy to Bonificazione. Possibly. We never know till we try. But an intelligent consideration of the maps of India might lead to the opposite conjecture. Let us examine them. They prove at any rate the value of silt deposit.

Here is the one showing "Physical configuration." You will understand it better if you are told that if the sea were to rise 1,000 feet, India would be reduced to an island about half its present size. Now look at its river system. The whole of the drainage of the Himalayas, north and south, pours its wealth into India (Tibet gets none of it) in three great systems. There is the Indus system, which derives its waters from both

northern and southern sides of the range. There is the system of the Ganges fed by a succession of rich rivers along its length, each richer than the one above. There is the Brahmaputra system, which carries the splendid soil that has formed Assam and Eastern Bengal. Simla, as befits the residence of the great Viceroy, is a corner-stone of the building. The rain that falls on the roofs of Viceregal-lodge descends on one slope to the Arabian sea; on the other to the Bay of Bengal; and in almost direct line from the Viceroy's house, on the other side of the vast mountain range, is the mutual starting point of the Indus and Brahmaputra, destined after long journeys to east and west, during which they drink in the drainage from the Northern inclines, to turn round at last, with all their riches, abruptly into India.

The remaining drainage is with minor exceptions that which flows east and west from the island you were asked to imagine, more, much more, east than west because there is a general trend to the east from the mountain wall which rises out of the western sea.

What in past ages became of the silt carried by all this drainage can be best understood by looking at the geological map. You will observe how simple is the geological surface of India. Neglecting small patches there are only three great sections, the alluvial deposit, the trap or black soil, and the Archæan rock.

You will at once see where the silt from the southern slopes of the Himalayas has gone. It has formed or at any rate overlain the great alluvial sea, if I may use the term for dry land, which sweeps round from above Bombay by Peshawar to Calcutta. Drainage from the northern slopes has made almost a Nile of the Indus, and, looking at the area it has built up, more than a Nile of the Brahmaputra. The silt of our island drainage has formed strips and deltas of pure alluvial soil on the river banks and along the sea coast.

The map, however, does not show those silt deposits which the geologists have not classed as alluvial *inside* our island, though we know that there are rich valleys of level black soil within the trap area; that there are extensive rice tracts in the south of India; that there are here and there vast pockets of rich soil.

The comparative value of the pure alluvial, let us call it silt, which surrounds the island can be partly indicated by the next map, that showing density of population. Naturally people crowd on to the best land and you will at once see how the colour darkens along the Himalayan plain; how it deepens as it approaches the delta of the Ganges; how dense are the patches which crop up along the deltas of the Eastern coast; and how everywhere the darkest colour prevails on the alluvial soil or silt. I may be challenged by the suggestion that population follows the rainfall as well as the soil. This is also true. But the dark patches in Madras, where there is less rainfall than on the slopes above, are significant of the attractive influence of alluvial soil.

Time will not permit me to take you round India, and I will confine your attention to that half of the great alluvial plain which is traversed by the Gangetic system of drainage, and is known as the Gangetic valley. Umballa, opposite our viceregal cornerstone, may be taken as the summit of the watershed between the Arabian Sea and the Bay of Bengal. The distance from Umballa to Calcutta is roughly 1,000 miles, and the fall 1,000 feet, or just one foot in the mile.

It is not difficult to understand that, gentle as is the descent, the general law of all slopes must prevail, and that the lightest and most fertilizing particles of silt are carried furthest. Hence we find sand prevailing near Umballa, loam or a mixture of sand and clay in the Upper Provinces, and clay in Bengal.

The tendency to lighter soils above and heavier soils below, is intensified by the circumstance that the monsoon rainfall increases as we proceed along the Himalayan range from opposite Umballa to opposite Calcutta. Heavier rain means more abundant forest vegetation. Consequently the silt washed down from the mountains becomes, as we follow the increasing rainfall, richer and richer in those fertilizing ingredients which go to make clay, at the same time that a more and more abundant quantity is carried down.

Thus there are four factors which have to be considered. Downflow of plains silt; rainfall; quality of mountain silt; quantity of mountain silt, all increasing as we descend from Umballa to Calcutta.

Let us now restrict our area of observation more closely and confine our attention to the upper half of the Gangetic valley, excluding the richer clays of Lower Bengal. What can be done in that region? We cannot alter the rainfall, we cannot improve the quality of mountain. But we can check the downflow of plains silt; and we can arrest some of the mountain silt. At present we allow the old silt to be stolen away, and the new silt to slip through unused.

The facts which I wish to impress upon some

minds are these, that the Himalayan drainage which must have once built up this vast Gangetic plain has now been concentrated into great rivers; that these rivers have, too frequently, cut deep channels for themselves in the plains which they created; that they have not only ceased to fertilize the land with fresh deposit but actually erode and gradually but continuously carry away the silt that they once laid down; that they are assisted in the work of destruction by the numerous feeders which each year eating through rich layers of deposit carry the most fertile elements of the old silt into the Jumna, Gogra, and the other large rivers which utilise the Ganges as a drain for hurling their stolen wealth into the sea. How I wish I could show you the hideous belts of gullies which flank so many of our rivers and their feeders, and which in the Jumna sometimes stretch inland for miles beyond its banks. You could then see for yourselves how the riches deposited by past ages are being gradually filched away.

But the cloud has a silver lining. For it is in those very regions in which good silt has been once deposited that good silt can be again laid down. And it is those very regions where State action is probably most needed.

It is interesting to notice in reviewing the replies from provinces, that almost the only tracts where the cultivators adopt the practice of holding up silt are, putting aside ricefields, broken and hilly lands, where each ryot builds up his little fields by dams and terraces that catch and hold up a few spadefuls of comparatively poor earth. But with negligible exceptions no practice of the kind is reported from the vast alluvial plains. Naturally. For there we have to arrange for the bridling and control of drainage over extensive areas or for long distances and must work with large schemes under competent experts. The ryot can do nothing alone. But, and this is the point I am aiming at, we shall be dealing not with the poor soil of hill slopes and rugged land but with the good soil of old silt and with the good soil of new silt. Surely, if it is worth while for the cultivator to arrest the poor washings of his hillside by his own petty efforts, it is worth while for the State to arrest on his behalf the rich silt on the alluvial plain. Only the other day I met the manager of some very extensive estates in Oudh, which lies in the region under discussion, who told me that during the last rainy season a small river, breaking loose, had deposited in one direction a huge area of coarse sand, and in other directions as huge an area of fine silt, so fertile that every cultivator was holding up his hand for a bit of it.

Now, we have seen how the Italians, bridling their stream, analyse every section of its water and apply to the land whatever kind of silt may be useful; coarse sand it may be to the bottom; fine silt above it; and finer silt still on the surface. Is not this the example to be followed in our great alluvial plain?

As I have said, I must not attempt to carry you further round India, where conditions vary at every stage. But the great principles of Bonificazione—the control of drainage and the capture of silt—are, *mutatis mutandis*, capable of application in every part of the country.

I will, however, take you for a brief journey to that one part of India where our splendid engineers *have* bridled the great rivers of the North to use their waters for irrigation, and, to some extent, lately, for Bonificazione. My object is to show you how small in extent is the area with which they deal compared with that of all India. The map shown indicates geographically the country traversed by canals; the diagram demonstrates the contrast between the canal-irrigated area and the cultivated area of British India 10 years ago; and here are the figures of the most recent returns, a decade later. Total culturable (not cultivated) area of British India 420 millions of acres; total area irrigated from canals, 13½ millions, Let us be liberal and allow the canal department 20 millions of acres, so as to include all their irrigable land as well as new schemes. Still, that will be less than 5 per cent of the whole. Now, the point I want to bring out is this: that in all India it is only this 5 per cent. area that is equipped with any engineers whose duties require them to examine the conditions and capabilities of the land; that elsewhere the man of the Public Works is confined to roads and communications; that unless for aligning a new road or railway he is debarred from travelling right or left of his hedges; that he has no opportunity of studying the character of the surrounding country and none of acquiring the agricultural knowledge and instincts which are developed in the man of canals in the course of his duties and without which no schemes of Bonificazione can be successfully designed. Here, indeed, we are led to the very question discussed at the Ravenna Conference, whether the example of Germany and France should not be followed in bringing agriculture and engineering into closer union

by training agricultural engineers. This is a question which is not being neglected in India, but it does not affect the present argument, which is, that as matters stand there are some 400 million acres out of a total of 420 millions in which there is no engineer of any kind outside the road and the railway; in which the character of the country has never been professionally examined; and in which the problems involved in the preservation and improvement of the soil have never been professionally studied.

There is no doubt, however, that as time goes on, and when railways and canals can spare the men, Agricultural Departments will be equipped with engineering experts, and that the capabilities of each province for Bonificazione will be satisfactorily ascertained.

One more word. The engineer will require a map showing the drainage of the country before he can suggest any scheme for Bonificazione. I will explain how such maps have been made at comparatively trifling cost. Every field on a large scale village map, already existing, is marked by the village map keeper with an arrow showing the direction in which the water flows off the field; broader arrows are then roughly drawn along the main drainage lines plainly indicated by the field arrows. The village maps placed together show the continuous drainage lines of any given tract. Reducing these by pentagraph, a map of any scale can be provided. The only expenditure is the pay of the pentagrapher.

I gave a first trial of this system some years ago when requiring a drainage map of the district of Cawnpore, an area of 2,400 square miles. I show here a section of about a fourth of it—600 square miles. You will see how it indicates in great detail where the land is water-logged, where it is being too rapidly drained and probably eroded, and so on. The system is now adopted in the canal department as providing the best basis for the alignment of canal distributaries, and would be equally useful in designing schemes for Bonificazione.

A difficulty to be faced lies in the circumstance that in the greater part of India the land is in private hands, generally in small parcels. Italy got over a similar difficulty by proclaiming a campaign against malaria, but it is possible that no such course could be taken in India. The ultimate solution of the difficulty may I hope be found in the reforms which have been begun in the education of the people, and which will, by bringing them into sympathy with agricultural improvement, secure their co-operation. Thus in some provinces the village schoolmaster passes through a course in the school of agriculture; in all provinces the rural schools teach the ryot's son all about his father's fields and what grows in them; the official staff whose duties involve field inspection—and there are about 15,000 of them—are all passed through the agricultural schools; the higher officials, are in growing percentage, selected from that staff; the scholars in many advanced schools receive an education more practical than literary, and are encouraged to adopt practical professions; the sons of the landholders are beginning to enter the agricultural colleges, and the higher castes generally are finding out that the literary professions are too full and that they too must turn to trade or to agriculture for a living. The time has passed when a Brahmin student could give the answer recorded in the books of a university 30 years ago to the question how to graduate a Danish steelyard. "I call this question a downright violation of the law of God," he replied. "Are we coolies or petty shopkeepers that we should graduate the Danish steelyard?"

I wish in conclusion to explain why I have not said anything about the effect of Bonificazione on malaria in India. Partly because I am not competent to deal with the subject, partly because I am sure that this aspect of Bonificazione will receive the fullest consideration from those who are competent. The State has never grudged a rupee for the protection of the people against devastating disease, and, if in the course of time it sees its way to improve their health by schemes of Bonificazione, is not likely to withhold money or men. Agricultural improvement took precedence of sanitation when Italy began its work and is now welcomed as the *sovrano remedio* against malaria. Perhaps history may run the same course in India.

DISCUSSION.

The CHAIRMAN:—I am sure you will all agree that the paper we have just heard has been most interesting and instructive, so instructive in fact that I wish your Chairman had more technical and expert knowledge of the subject and was able to speak about it on something like the high level attained by the author. But though I have always taken the keenest interest in canal irrigation in India, and did much while I was at the head of the Public Works Department to urge its claims and to secure a larger share of the revenue of the country to be spent on extensions of the canal system, I cannot say that my attention was ever specially drawn to the question of river silt

except in one way—it was always spoken of in the Irrigation Department as an unmitigated nuisance. Whether it was the silt that collects in the canals, especially when the water is checked and led off into side channels or distributaries, which involved a closing of the canal during the periodic and expensive cleanings, and presented constantly growing difficulty as to how to deal with the silt when cleared out, or whether it was the silt brought down by the hill streams from the outer hills of the Himalayan range, and spreading out in cone-shaped fans to the destruction of the fertile land it covered, it was generally looked on as a hostile and dangerous element. One was conscious, however, that in this mass of coarse sand and pure silica there was at times a mixture of fertile soil, for one saw in the broad dry bed of the Jumna at Delhi, or the Ganges at Cawnpore and Farukhabad and similar places, small patches which the keen eye of the agriculturist noted as suitable for cultivation, and which he turned with abundant manure into melon beds. Again, in the tank system of Madras and Mysore, where the gentle sloping valleys are crossed by numerous embankments one above the other, holding up and passing down the water from the highest to the lowest, it is well-known that the soil brought down from the sides and deposited above the embankment is extremely productive, and the crops grown in the tank bed when the water is run off are often more valuable than those in the rice fields below the embankment, into which the water is sedulously led. A similar case to this has been described by the author as coming under his observation in Gwalior. And here I may say, in passing, we have a curious instance of what is mentioned in the paper, the necessity that the engineers should also be agriculturists. The Madras engineers who have so skilfully controlled and organised the vast tank system were, and perhaps still are, strongly opposed to the cultivation of crops in the tank bed, on the ground that it tends to fill up the bed and decreases its water capacity; and in the Mysore famine of 1877 Colonel Scott-Moncrieff and I had to use strong measures to get this restriction cancelled, and the starving ryots permitted to raise crops on these areas. But the idea mentioned by the author that you can not only ascertain by chemical analysis when the flood waters of a river contain fertilising soil, but also can ascertain beforehand when they are going to contain such soil, so as to be able to turn only such water into the fields, and only during the short time for which this condition lasts, was certainly never mooted in my time, and deserves very careful consideration by our Indian engineers. I confess that it seems to me to be surrounded by much practical difficulty, for you must have the proper officer in his place at the proper time to turn on the water, and if that time only occurs six or seven times in the year, and only lasts a few hours, I fear that, being an Indian subordinate, he will often not be there in his place. Moreover, it is hard to see how it will pay to construct sluices and distributaries, and keep them in constant repair for such very occasional use; still, hard as the process is to realise, what has been accomplished in Italy ought to be practicable in India, and we ought not to be deterred by *prima facie* difficulties. Sir Edward Buck's comprehensive survey of Indian geography, together with the lantern slides, which will not, I fear, be available for the reader of the paper in the Society's *Journal*, has given a fairly clear idea of the tracts to which he would propose to apply the principle of Bonificazione by the deposit of fertilizing silt. The instances given at the beginning of the paper were all on a small scale, and the interesting method he describes of the building up of hills, and of dealing with ravine-riddled tracts, like the banks of the Jumna, seem to require minute attention to contour lines, and the laying-out of surface drains and trenches, rather than the application of river silt. But his description of the way in which the whole of the Indian plains have been created by the action of great rivers, which, to use Tennyson's words, "draw down Æonian hills, and sow the dust of continents to be," seem to show that the system should not be—like the Ganges and the Jumna, and the five rivers of the Punjab—applied to the great rivers which have cut channels so far below the surface of the land, but to the smaller streams rising and running in the plains themselves, like the Limone river in the Ravenna province, or the Isan river in the Cawnpore district. And while by the help of these rivers, the fertile soil from the head of their basins might be caught and distributed over the lower part of these basins, it would be even more worth while to pour the fertilizing silt on barren and unproductive land, such as the large tracts of "oosur" land, impregnated with saline efflorescence, at the reclamation of which Sir Edward and I worked together long ago. Then we come to the question of the cost of the operation, and I have already suggested fears on that head. In his official report, on which the paper is largely based, and which he has been good enough to lend me, Sir Edward mentions four cases of private works which he has culled from official documents in which the value of the land was greatly raised, and of which the average cost per hectare, in the four cases he has mentioned, was 567 francs, which corresponds to 230 francs per acre, or say £9 or 135 rupees per acre. Assuming that the outlay was borne by Government, as it would be in the case of canal construction, would such an expenditure be remunerative? Could the interest on the capital be recovered by enhancing the rent? We know that in the case of canals it is a rough general rule that the capital cost should not exceed Rs. 50 or Rs. 60 per acre if the canal is to be commercially successful. The meaning of that is, that the interest on Rs. 50 at 4 per cent. is Rs. 2, and the cost of upkeep, distribution, &c., is about the same figure, and that the ryot will hardly ever be willing or able to pay more than Rs. 4 an acre for the use of the water. Here, with a capital outlay, on the basis of the Italian figures, of Rs. 135, the

interest would be between Rs. 5 and Rs. 6, and there must, I presume, be some regular charge for upkeep, so that I fear we are getting into almost prohibitive figures. Perhaps, however, work of this kind can be done at a lower cost, Indian labour being cheaper than in Italy. I trust I shall not be thought to be unduly critical or pessimistic in these remarks. They are difficulties which have struck me in reading the paper, to which I have already referred, and the proof of this paper, and it is very likely that Sir Edward Buck may be able to dispose of them in his reply. And we must not forget that he mentions another kind of Bonificazione besides that of making the fields more fertile, viz., the benefits to health which will occur from raising the level of low and marshy soil so that the pools may be filled up in which mosquitos breed, and thus the main source of that terrible curse, malarial fever, may be removed. No doubt there are many parts, especially in Eastern Bengal, where great benefits would accrue from such a process; but whether it could be, as he suggests, effectually applied to the Terai seems to me doubtful. There, as you know, the trouble comes not from lodgment of surface water but from the springing up from below of the water of the streams, which get lost in the stony talus at the foot of the hills, and reappear gradually at a lower level. I can hardly see how the imposition of any layer of silt on the surface could prevent this reappearance. However this may be, I think we may heartily thank the author for the very interesting and instructive information he has bestowed upon us, and may support the suggestion he has made, as being well worthy of careful examination, and as containing possibly some seminal ideas which may be of great value to the country. But before closing I have still, in my temporary capacity as a doubter, one other reflection to make. These great agricultural improvements, of which everybody who has travelled across Lombardy, down the valley of the Po, must have at least some superficial knowledge, have been carried out by Italians for Italians, the landowners and the cultivators co-operating with the engineers and the officials, and realising that the work will do good to the country. We have heard of Count Pasolini's grandfather "the great statesman and equally great agriculturist," and we are told that private owners are so satisfied with the financial advantages of the silt system that the practice is rapidly spreading. Can we be sure of such co-operation and such enterprising landowners in India? Unfortunately we cannot. Our engineers are foreign to the country, and if even in Italy it is admitted that engineers are apt to be too professional and too little alive to agricultural wants, still more is that likely to be the case with English engineers in India. And so with the natives, even the leaders and most educated among them. We have trained them in literature, and Herbert Spencer, and so forth, and taught them to demand a larger share of political power, which they are doing, much after the fashion of suffragettes, but we have not done much to teach them the duty of landowners towards the improvement of their land, nor has agricultural engineering become a profession of dignity and profit. Sir Edward speaks hopefully of the agricultural schools and the practical training of the village schoolmaster and the village accountant, but I fear they are as yet in a very rudimentary condition; and before his idea as to reclamation and fertilization can be carried out on a large scale, through local agency and with popular support behind them, we must follow the example given by Germany and Austria, by France and Belgium, and set up a dozen Cirencester Colleges, one in each province, or even something more advanced than Cirencester, and with a larger outlook, so as to create a class which will do in India what English landlords do, as regards experiment and investigation of the qualities and possibilities of the soil. When this is achieved, there may be some hope of saving agriculture from its liability to seasonal catastrophe whenever the rainfall is untimely in its incidence or deficient in its quantity. May I, in conclusion, say a few words to express my admiration of the great part which the Italian Government has taken in this work? Sir Edward tells us that they have applied this system, or are in process of applying it, to about 10,000 square miles, have reclaimed the marshes, filled up the swamps, covered the whole with fertilizing soil, and almost extirpated the malarial mosquito, at the cost of £9,000,000. And this has been done by the poorest country in Europe, in order to improve the sanitary and economic condition of its people, in spite of very heavy taxation, and almost in silence; for in all the discussions I have seen on Italian finance, I have never heard mention of this particular class of expenditure, nor any selfish suggestion for curtailing it in order to relieve the over-burdened taxpayer. Surely no grander work of far-seeing benevolence has ever been undertaken by any country, and we may heartily support Sir Edward Buck's advice to the Indian Government to study its methods, and, as far as the system is applicable to India, to go and do likewise.

Dr. J. A. VOELCKER said that he had listened with great interest to the paper, and he also had especial pleasure in recalling the great kindness which the author showed to him personally when he was in India endeavouring to investigate some of the great agricultural problems with which Sir Edward Buck's name and work had been identified. He had very rightly referred to the great value of silt, and told them that it was a material which ought by no means to be neglected, yet to some extent this had been the case in India. His remarks with regard to the chemical or fertilizing advantages of silt were perfectly correct. The principal advantage of silt was of a chemical nature, and consisted in actual elements of fertility—nitrogen, phosphoric acid, lime, potash, &c.—being brought on to the soil. The author might also have referred to another point having special importance in connection with

India, namely, the physical advantages attending the use of silt. In a country like India, where very much depended upon the retention of moisture in the soil, it was above all things essential, as nobody knew better than the Indian cultivator, to keep a fine tilth on the surface of the ground. In this way, cultivation and drainage were improved, and the moisture was kept in the land, thereby increasing the actual fertilizing value of the silt. The advantages to be derived from the carrying of water from rivers or canals depended upon four considerations. Firstly, whether silt was being carried with the water, or not; secondly, what kind of silt it was; thirdly, what quantity; and fourthly, at what time of the year, and for how long it was carried. The whole question as to whether silt could be economically used or not resolved itself more or less into a consideration of these four points; and it seemed to him that in India there was a great deal of variation in the conditions met with. He had seen the application of silt in many parts of India, and he had also seen other parts where it had not been used and where some thought it might have been. Silt, moreover, could not be spoken of in general terms, because it depended upon what it came from. There were some kinds of rocks which produced a silt which was not worth having, while there were other kinds which produced a silt which was immensely valuable. It was necessary to discriminate in the use of the one or the other. Then, if silt was coming down for part of the year only, it was a consideration whether any work of reclaiming it could be economically carried out. It was well known that perennial canals often contained no silt at all, and to let them go over the land was simply to increase the bulk of the water and to intensify the malaria which it was so desirable to remove. On the other hand, with what were called inundation canals, where the water was taken at flood-tide, not only water but silt was placed on the land; at the same time the drainage was improved, and an excessive quantity of water, which might in the long run produce malaria, was not stored up in the soil. He had recently read a paper, written in 1897, containing an account of some work done by the Agricultural Department of the Government of India on the question of the utilisation of silt, and he could not help being struck by the enormous variations shown, both in the kind of silt and in the time during which it came down, thereby emphasising what the author had insisted upon, namely, the need for further enquiry. He thought the author would agree with him that it would only be right, before the Government undertook any big scheme, to make careful enquiries, because he was sure that the scheme put forward was no universal remedy, which could be applied anywhere and anyhow. He had also had the advantage of seeing what was being done in Italy, having travelled across the plain of Lombardy. No one could help being struck by the immense fertility of this district, but it had to be remembered that the rivers of Lombardy carried down not only an enormous quantity of silt, but silt of a most valuable kind. In the case of India, as had been pointed out, it was quite true, that some of the most valuable silt was being run down to the mouth of the river, and thence into the sea; but if it was going to be all stopped in the upper parts of the country, it would be a case of robbing Peter to pay Paul; somebody would miss it down below. In travelling over India, one could not help observing that the native had a very fair knowledge of what was good, and what was not good, and he had only utilised on his own account the silt which was really valuable. He (Dr. Voelcker) was a little afraid that, if a big scheme of the kind suggested by the author were undertaken without due enquiry, and the engineers were not sufficiently agricultural, it might result not unfrequently in the utilisation of silt regardless of its quality. He, therefore, desired to emphasise the importance of Sir Edward's suggestion of the need of enquiry, and of the different Departments paying attention to the agricultural side of the matter, a point on which the author in his own work had always so strongly insisted.

Mr. R. B. Buckley, C.S.I., M.Inst.C.E., said the author mentioned that the text of his paper was, that wherever fertilizing silt could be found it was a grave error not to carry it on to the fields. He cordially agreed. The Chairman had said that his experience of silt was that all engineers regarded it as an unmitigated nuisance. He (Mr. Buckley) was an irrigation engineer, and did not at all agree with the Chairman's statement. If amongst those present there were any other irrigation engineers who had devoted their lives, as he had done, to trying to improve agriculture in India, they must have listened with special interest to the paper. Although irrigation engineers undoubtedly found silt a nuisance at times, they were fully aware of the good results it could produce when, as Dr. Voelcker had pointed out, the right sort was obtained. He knew several tracks of country which were sandy wastes when he first became acquainted with them forty years ago; they were now, after twenty years' irrigation from the Sone Canals, in Behar, fertile plains of rice, partly because they had obtained water, and largely also because they also had obtained fertilizing silt. That land forty years ago was rented for six or eight annas a beegah; when he was there eight or ten years ago it was let at seven or eight rupees. Another instance of the fact that rent could be largely increased by the proper distribution of the proper kind of silt was to be found near Patna. There was an old depression close to Bankipur which was filled up with the water of the Ganges every year, and received a deposit of silt; and he believed the rents of some of that land were eight and ten times as large as were received from land not possessing the same advantage. The Nile conferred great benefits upon all the lands it watered. It was estimated that it carried down to the sea a volume of no less than 50 million tons of silt a year, although it

contained only about $1\frac{1}{2}$ ounces in each cubic foot of water. Fifty million tons conveyed a small idea of what it really was, but it was an enormous volume. If the whole of Hyde-park and Kensington-gardens were covered up with silt to the height of the top of the Albert-hall, something like 50 million tons would be used. In the Indus there was something like $2\frac{1}{2}$ times the amount of silt there was in the Nile, but the Nile silt was, he believed, always highly fertilizing, and the Indus silt was not equally good. The Ganges, the main source from which the author proposed to carry out the improvement of the land, contained roughly something like three times the volume of silt that the Indus did — an enormous volume. The author was undoubtedly right when he said that, if the silt from the rivers of India was placed on the land, it would confer the greatest advantages on all agriculturists; but it was necessary to think for a moment or two what he proposed to do. The lands in Upper Egypt were, and had been for thousands of years, watered from the Nile. It had been estimated, from certain facts connected with the foundations of the two Colossi which are seated on the plain of Thebes that, in the course of 2,400 years, the Nile, which nearly every year had flooded the plain, had raised it by 6 feet, which worked out at a minute fraction of an inch in a year. That was what would be obtained in India if rivers, such as the Indus, the Ganges, and the Sone, were tapped, and the water put over the land to a depth of something like three or four feet every year. He thought those who had listened to the paper had rather gathered that the lands would be raised in a marked way. That could be done on a small scale in certain places, but it could not be done on a large scale over a great area, because the silt in the water was not sufficient. The author had said that the ultimate aim he had in view was to apply the system to 50,000 square miles of country, *i.e.*, something like 30,000,000 acres. He did not think Sir Edward quite appreciated how much was now being done, and had been done for years, in the same direction in India. The last returns prepared by the Government of India showed that 20,000,000 acres of land were being irrigated by the great Indian canals. That portion of this area which was irrigated during the flood season was now being more or less subjected to the same process which the author recommended for another 30,000,000 acres. The canals of India at the present moment tapped the rivers, and deposited the silt on the land. The Sone Canals, with which he was intimately acquainted, carried every year some 2,000,000 or 3,000,000 tons of silt, and deposited it on some 400,000 acres of land. The great Chenab Canal, the glory of the engineers of the Punjab, carried every summer season something like 5,000,000 or 6,000,000 tons of silt and deposited it on the land. The great inundation canals in the south of the Punjab and in Sind, and indeed every other canal in India, except those that took their water from reservoirs, were doing more or less the same thing. That is, they were carrying the silty water of the river, and depositing the silt on the land. The Chairman had referred with some doubt to the question of cost of Sir Edward Buck's proposals, and he shared the same doubts. Nobody would deny that, if the good silt could be taken out of rivers and placed on the land, it was an excellent thing. Analyses made by the engineers of the Punjab, and by those on the Sone Canals, showed that something like two-thirds of the silt was good, the other one-third being sand, and comparatively useless. But the important question was—What would it cost? In order to carry the water from the rivers, and place it on 30,000,000 acres of land, it was necessary to make canals to carry the water. The volume to be carried would be enormous, and the canals would have to be numerous and large. But what would that cost? The author had referred to what Sir Colin Scott Moncrieff had said with regard to the improvements in the Moselle district. The improvements were undoubtedly very good, but Sir Colin gave the cost at from £17 to £28 an acre. He did not mean to say it would cost that amount to carry silt from the Ganges and the Indus on to the lands of India, but it would certainly cost a very material sum. In the "basin" lands of Upper Egypt the cost on some 2,000,000 acres was between £3 and £4 an acre. If the author intended to reclaim or improve 30,000,000 acres in that way, he would have to make canals similar in style to those which had been already made in India for irrigation purposes. To construct similar works to irrigate 30,000,000 acres would cost about £100,000,000 sterling, and about £2,000,000 a year to keep them working. He also doubted whether it would be as easy to make such works in the Valley of the Ganges as it had been in the Valley of the Nile; the circumstances were not nearly so favourable. He did not say it was not a matter for investigation as to whether the system might not be applied in certain cases with advantage, but he did say that, before £100,000,000 sterling was invested on such works, it would need far more enquiry than had at present been given to the subject. At the same time, he wished to thank Sir Edward for having brought the subject to their notice, because he was fully aware of and highly appreciated the immense benefits which occurred when silt could be brought on to the land at a reasonable cost.

Professor W. J. SIMPSON, M.D., remarked that if the author could get the Government to accept even the experimental part of his scheme he thought he would have done a very great service to India. He had no doubt whatever that, in some parts of India, it would be possible, after due enquiry, to find some places in which the system could be applied. He had interested himself a good deal in the question of inoculation in regard to man, to render him more resistant to certain diseases, and had naturally interested himself also in recent

experiments in regard to improvement of crops by inoculation of the soil with nitrogen fixing bacteria. He recently asked Professor Bottomley, of King's College, who had devoted a great deal of attention to the subject, whether it was not possible that inoculation could be applied to some of the lands of India. The practice had been carried out very largely in America by agricultural parties with great success, and recently Professor Bottomley had made a large number of experiments in regard to the poor lands of England; by utilizing bacteria which only cost sixpence a packet, or even less, he had been able to produce crops which were equal in quality to those produced from land which had been manured at a cost of £2 an acre. Not only had Professor Bottomley succeeded with leguminous plants in inducing them to fix the nitrogen of the atmosphere by these bacteria, but he had extended it to other plants. It had struck him since reading the paper that there might be a possibility of applying such a cheap process to India, because it could be easily used by the Indians themselves, if the nitrogen fixing bacteria were prepared and the packets distributed with instructions for their use. He cordially thanked the author for his interesting paper, and hoped he would be more successful than the irrigation engineers believed would be the case.

Mr. T. H. Middleton (Assistant Secretary, Board of Agriculture and Fisheries) confessed that he had come to the meeting in rather a sceptical frame of mind towards the subject of the paper, as he happened to know something of Indian conditions. He rose for the purpose of saying that, having listened to the paper and the discussion, he should go away feeling that he had got a new light on the subject which Sir Edward had placed before them. The author had, in his opinion, given them an idea which was distinctly worth following out. He remarked that the difficulties which had been referred to in connection with the agricultural engineer and the native cultivator were not serious difficulties. The agricultural knowledge which would be required by the engineer in charge of such works as the author had referred to would be very small; it would be knowledge which could be quickly acquired by anyone at all interested in the subject; and everyone who knew the Indian cultivator knew his skill in dealing with irrigation water, and the care he took in preventing erosion.

Sir Edward Buck, in reply to the remarks the Chairman and Mr. Buckley had made with regard to the cost, said he could only refer them to the observations he had made with regard to the little place near Cawnpore, outside the area being dealt with by the canal engineers, which is the only portion in something like 50,000 square miles under that kind of treatment, and the man had made it pay, having quadrupled the value of the land, though he had done that more by preventing the escape of the old silt than by obtaining new silt. He wished it to be clearly understood, however, that he had not made any proposal for action; the only thing approaching to a proposal was that the surfaces of the country should be studied by competent engineers, who should decide whether or not anything of the kind could be profitably undertaken. He had not ventured to go further than that, because he was not competent to do so. He referred his audience to the text with which he had begun, namely, that "Wherever fertilizing silt is available it is a grave economical error not to profit by it." By the word "economical" he inferred profit. If it did not pay, the work, of course, should not be undertaken, unless the malaria and unhealthiness of the country were so great that, as in Italy, the health of the people demanded that the expenditure should be made; but agriculturally nothing ought to be done unless it could be proved to pay.

On the motion of the Chairman, a hearty vote of thanks was accorded to Sir Edward Buck for his valuable paper, and the meeting terminated.

Mr. J. D. Anderson writes:—Sir Edward Buck's admirable and most interesting and suggestive paper on the "Applicability to India of the Italian Method of Utilizing Silt," deals only with those comparatively elevated portions of the Gangetic plain, where the great rivers have affluents, and do not frequently overflow their banks. The problem is a different one in Central and Eastern Bengal, where the minor rivers and channels are effluents, not affluents. In Eastern Bengal, now probably the most healthy and prosperous region in Northern India, the beneficent action of the greater streams in pouring fertilizing silt into the marshes lying behind the raised river banks, cannot be questioned. For instance, there is in this region a *pergannah*, or fiscal division, called Khaliajuri, which, a hundred years ago, was a vast sheet of water. It had practically no "assets," to use the revenue phrase of the day, at the time of the Permanent Settlement, and was permanently assessed at a merely nominal sum. Since then, the turbid and silt-laden stream known as the Kangsa has been pouring soil into its marshes through innumerable winding *khals* or channels, and it is now one of the most prosperous and thickly populated tracts in Eastern Bengal. It might indeed serve as a typical example of "unearned increment" under the Permanent Settlement. This tract is, of course, subject to deep floods during the rainy season, but the inhabitants, with the usual Indian adaptability, have suited their life and cultivation to their surroundings. The rice they grow is of the long-stemmed variety, which rises with the rising flood and loves deep water. The villages are built on artificial islands, and are surrounded by cow-sheds sloping to the water's edge. The villagers go out in their boats and cut marsh grass for their stall-fed cattle, whose rich milk furnishes the well-known "Dacca cheese," so called,

not because it is made, but because it is sold, in Dacca, the capital of the new province of Eastern Bengal.

In Central Bengal the conditions more closely resemble those of the valley of the Po and of similar tracts in Japan. The rice grown is not of the long-stemmed variety, and much of the land is given up to fine crops of jute, to which heavy floods are fatal. Consequently, many districts in Central Bengal are surrounded by expensive embankments, which are carried across the mouths of the channels which should be kept open for the natural dispersal of the fertilizing silt. The result is that the silt, instead of being spread over the fields, is deposited on the bed of the river. Consequently it becomes necessary to add continuously to the height of the embankment, until nature, in a year of high floods, takes her revenge, bursts the embankment, and destroys the standing crops. There is much loss of property and sometimes acute distress. But the cultivators are in the long run remunerated, for the fields, refreshed by the silt-laden flood, often yield bumper crops. It would seem that here engineering skill might improve on the Italian example by aiding nature to distribute the silt of the great rivers without causing the floods against which the present blind and unpierced embankments are raised.

The question is not merely one of agricultural prosperity, for these embanked districts have an ill-fame as the abode of "Nuddea fever" and "Burdwan fever," remittent agues due, no doubt, to the mosquitoes that breed in the water-logged area within the embankments. Such is the state of some of the most populous districts of Bengal, quite close to Calcutta. No doubt it would be impossible at this stage to remove the embankments. That would involve too harsh and sudden a change in the habits of the people. But perhaps it would be possible to admit the floods into the low lands behind the embankments, in such a fashion as to enable them to carry the silt without damaging life and property. The discussion on Sir Edward Buck's paper showed that in the tracts which drain into the great rivers of Northern India, questions of expense may render it impossible to apply the Italian system of irrigation. But in those deltaic tracts, which drain out of the great rivers, it might perhaps be possible to discover some middle way between shutting out the river water altogether, and the sudden and destructive floods which result from the consequent raising of the river beds. It is some years since I served in Central Bengal, and I make my suggestion with much diffidence, inasmuch as it is possible that steps have already been taken in the direction of controlling rather than excluding the silt-laden flood water. Italian and Japanese experience has shown that the bed of a river is not the proper place for rich and fertilizing silt. On the other hand, the rivers of the Gangetic delta are so swollen and strong that it will necessarily tax engineering skill to control their waters. I trust Sir Edward Buck will excuse me for adding a corollary to his extremely interesting paper. Bengal is so often regarded as the granary of Northern India that it does not occur to administrators to suggest a possible addition to its agricultural resources. As a matter of fact, however, Central Bengal is not so prosperous as is commonly supposed if the bulk of its population be considered, and the prevalence of malarious fever has for the last fifty years caused anxiety to the administration. It is just possible that Sir Edward Buck's inquiries in Italy may enable him to suggest some remedy, though, of course, the comparatively small and stagnant Italian rivers present a much easier problem to the engineer and to the riparian cultivator than the great streams of Bengal.

RAILWAYS IN THE CONGO FREE STATE.

Two important steps have recently been taken on the further development of the railway system in the Congo Free State. Two new lines have been opened that will very materially aid in giving access to that country. One runs from Stanley Falls, where the river Congo ceases to be navigable, in an easterly direction towards Mahagi on the Albert Nyanza, a distance of 695 miles, and the other starts from Stanleyville, the city by the falls, and running from north to south, partly by boats on the navigable portions of the Upper Congo, and partly by a railway for such portions of the stream as are not navigable, ultimately is bound for the district of Katanga, in the extreme southern portion of the Free State, where there are great copper and gold fields. Of this latter line the road was opened on September 1, 1906, from Stanleyville to Ponthierville, and is now in operation for a distance of 79 miles. The following, according to the American Consul at Antwerp, are the terms and conditions on which these two great projects have been undertaken. The Congo State contracted to build the road bed on account of the railway company, which agreed to supply the entire superstructure and the rolling stock free on board at Antwerp. Until the opening of the line, all the work done by the State is charged for at cost. The State further guaranteed to the company 4 per cent. interest on its capital, and is to assign to it for every £1,000,000 of capital invested 10,000,000 acres of land, which they are to dispose of jointly, dividing the profits therefrom in equal shares. When the Government first started these enterprises seven years ago, it attached greater importance to the line projected to the Albert Nyanza Lake and the Nile. It therefore pushed all the preparatory work for this section, so that the route was already surveyed to the lake by 1902. But while the railway company was forming, and these preparations were being made, the political interests of the Congo State in this line to the Nile underwent a change. At the same time the discovery of rich ores in the district of Katanga at once made the construction of the southern lines

the more urgent and the more important of the two. This new road, 79 miles in length, runs through a country covered mostly with primeval forests and intersected by numerous streams which had to be crossed by twelve bridges, partly of wood and partly of steel. Above Ponthierville to Kindu there is a stretch of navigable water in the Congo, 217 miles long, which is traversed regularly by two steamers of 30 tons each, by another vessel of 100 tons, and by a tug boat, all brought from Belgium. The trip to Kindu takes four days, and from two to three days for the return trip. The width of the stream varies, being in some places only 600 yards broad, but on the average it is 2,000 yards wide and abounds in islands. At present much work is being done to improve the channel of the river by dredging. From Kindu the navigation is being continued for the present, when the water is too low, by a small steamer up to Sendwe, 14 miles above Kindu. From this point another railway will be necessary to Buli, about 186 miles distant, to get round the next unnavigable portion of the stream, and a large number of people are now at work upon this. It is expected that the number will, in a short time, amount to 5,000. Above Buli another navigable part of the Congo will be found, about 372 miles long, up to the northern portion of the district of Katanga, and this section is now being surveyed to complete this new and great system of railway and river transportation through the heart of Africa. Thus another link has been added to this wonderful line, the construction of which was pronounced to be impossible, because of the supposed insurmountable difficulties presented to engineering skill. Only a few years ago, in 1898, the first part of it was opened, the well-known Cataract Line around the falls of the lower Congo. It takes twenty-one days for a voyage from Antwerp to the landing place, Matadi, on the Congo, and from twenty-two to twenty-five days for the inland trip by rail and by river to Stanleyville and Ponthierville, so that these places can be reached in forty-five to fifty days from Europe. A ton of goods can now be carried from Antwerp to Stanleyville at a cost of about £10.

ADMIRALTY CHARTS.

The following is the official list of charts issued by the Hydrographic Department of the Admiralty in February and March:—

February.—New Charts.—1899—Asia Minor:—Kalimno, Kappari, and Kos channels. 2579—West Indies:—Cuba. 3630—Plans in the neighbourhood of Magellan strait:—Fitzroy channel, port Bobillier; Guzman inlet. 3612—China, east coast:—Port Shelter and Rocky harbour. 3621—Plans in the islands south of Kiusiu:—Isso; Miyanoura. 3614—Japan:—Nanao wan. 3628—Japan, Kiusiu, East coast:—Ariake wan. 3622—Australia, east coast:—Port Jackson to cape Byron. 2873—Anchorages in the Solomon islands:—Beaufort bay; Sutulahia anchorage; Vura anchorage; Auki island harbour; Sandfly passage; Albatross bay; Lengo to Teterre; Ngora fu harbour. New Plans and Plans added.—1582—Harbours on the east coast of the Adriatic. Plan added:—Narenta river entrance and anchorage.

Charts that have received additions or corrections too large to be conveniently inserted by hand, and in most cases other than those referred to in the Admiralty Notices to Mariners.

No. 2154—England, south coast:—Newhaven. 2050—England, south coast:—approaches to Spithead. 2255—England, south coast:—Weymouth and Portland. 30—England, south coast:—Plymouth sound and the Hamoaze. 32—England, south coast:—Falmouth harbour. 2879—Wales, west coast:—Milford haven. 1951—England, west coast:—Liverpool bay. 2131—Scotland, west coast:—Arran island to Gare loch. 1828—England, east coast:—The Downs. 1607—England, east coast:—North Foreland to the Nore. 2151—England, east coast:—Broadness to Mucking light. 1834—England, east coast:—Bishops ness to Rochester. 1491—England, east coast:—Harwich harbour. 109—England, east coast:—entrance to the river Humber. 3497—England, east coast:—Hull road. 2567—England, east coast:—Tees bay. 1934—England, east coast:—River Tyne entrance. 1777—Ireland, south coast:—Queenstown and Port of Cork. 60—Channel islands:—Alderney and the Casquets. 2626—Channel islands:—Guernsey, Herm, and Serk. 62b—Channel islands:—Island of Jersey. 2289—Norway:—The Skagerrak. 3415—Baltic sea:—Approaches to Räfsö and Biörneborg. 144—Spain, south coast:—Gibraltar. 194—Malta and Gozo islands. 867—Bermuda:—From the Narrows to Hamilton. 1127—River St. Lawrence:—Montreal harbour. 337—North American lakes:—Toronto harbour. 324—North American lakes:—River St. Mary from East Neebish to point Iroquois. 1638—Gulf of Mexico:—Breton sound to Dernière island. 1499—Alaska:—Cross sound to Kadiak Island. 616—Africa, west coast:—Sierra Leone river. 1920—Africa, south coast:—Table bay. 1849—Africa, south coast:—Simons bay. 2404—Singapore main strait from Tree island to Batam bay. 1466—China, east coast:—Fotaumun pass. 3480—China, north coast:—Shantung promontory to Nagasaki.

March.—New Charts.—121—Sweden, west coast:—Torbiornskier to Väderöbod. 3633—Alaska:—Dixon harbour. 3620—China, south coast:—Canton harbour. 3617—Japan:—Yume zaki to Modoro zaki 3623—Australia, east coast:—Cape Byron to Lady Elliot island. New Plans and Plans added.—108—England, east coast, Skegness to Blakeney; New plan:—King's Lynn docks. 1858—Central America, plans in Yucatan; Plan added:—Port Morelos. 1304—Plans on the coast of Chile; New plan:—Comau or Leptepu inlet. 2395—Ports in the Philippine islands; Plan added:—Paskao anchorage. 1579—New Hebrides, Malekula island, southern portion; Plan added:—Pangkumu bay.

Charts that have received additions or corrections too large to be conveniently inserted by hand, and in most cases other than those referred to in the Admiralty Notices to Mariners.

No. 1547 — Ireland, west coast: — River Shannon, sheet II. 1548—Ireland, west coast: — River Shannon, sheet III. 1541—Ireland, west coast: — River Shannon, Sheet IV. 1549 —Ireland, west coast: — River Shannon, sheet V. 2552—Ireland, south coast:—Dunmanus bay. 1875—Germany: —Elbe, Weser, and Jade rivers. 2302—Baltic sea: — Gulf of Bothnia, sheet VII. 3300—Baltic sea; gulf of Riga:—Windau. 798—France, west coast: — Douarnenez bay and approach. 419—Adriatic:—Anchorages and channels in the gulf of Cattaro. 2843*a*—United States, east coast:—Chesapeake bay, sheet I. 2818—United States, east coast:—Hampton roads and Elizabeth river. 2866—United States, east coast:—Winyah bay and Georgetown harbour. 1217—Gulf of Mexico: —Florida strait, south part. 486—Gulf of Mexico:—Jamaica and the Pedro bank, &c. 1266—Islands and banks between San Salvador and San Domingo. 456—Jamaica:—Port Royal and Kingston harbours. 2600—Leeward islands:—San Domingo to Dominica. 525—Gulf of Mexico:—Boca Grande cay to Tortugas cays. 1329—South America, east coast:—Bahia Blanca to Union bay. 587—Central America:—Burica point to Mangrove bluff. 629—Africa, west coast:—Walfisch bay. 2089—Africa, east coast:—Tugela river to Delagoa bay. 1235—Persian Gulf:—Mouth of the Euphrates. 1884—Bay of Bengal:—Arakan river, Akyab. 794—Malaca strait: —Pulo Berhala to cape Rachado. 2109 — Borneo, sheet VI.:—Barram point to Nosong point. 900—Celebes: —Tilamuta harbour to Tanjong Tuladenggi. 1740—China: — Canton river, sheet III. 1262—China, south coast;—Hong Kong to gulf of Liau tung. 1760—China, east coast:—The Brothers to Ockseu islands. 1761—China, East coast:—Ockseu islands to Tung Yung, &c. 2347—Japan:—Nipon, Kiusiu, and Shikoku, and part of the Korea. 1030—Australia, east coast:—Great Sandy strait, southern portion. 1031—Australia, east coast:—Great Sandy strait, northern portion. 179—New Hebrides:—Espiritu Santo island.

These charts are issued by Mr. J. D. Potter, 145, Minories.

GERMANY'S MARITIME INTERESTS.

According to recent reports of the American Consuls in Germany a publication has recently been issued by the German Government on the development of the German maritime interests in the last decade. It was probably intended to assist the Bill before the Reichstag for the further increase of the Imperial navy. Facts and figures are given to exhibit the enormous increase in the maritime interests of Germany during the last ten years, an increase which is represented by the German Admiralty as eminently satisfactory in itself, and yet not without anxiety for the future. The report shows that the comparison instituted between Germany and foreign countries makes it clear that Germany in many directions has a marked superiority over other countries, and that this advantage will in certain directions be long maintained. On the other hand there is a growing competition with German trade in foreign countries and foreign markets, which must require from Germany the most energetic efforts for the maintenance of its national welfare since any relaxation of such effort must involve the country in the danger of falling behind, and of being dislodged from the position of advantage which it has acquired at such great cost. It is indispensable to the continued prosperity of the empire to maintain and increase the economic relations with foreign countries, especially those across the sea. Since the foundation of the empire its population has increased by nearly 20,000,000 - from a little less than 41,000,000 to a little over 60,000,000. Its rate of increase is now greater than that of any of the larger European States, being over 800,000 annually, and surpassed only by the rate of increase of the population of the United States. Formerly the volume of emigration exceeded that of immigration, but since 1895 this has no longer been the case. Not only has emigration been reduced, but from 1895 to 1905 the surplus incoming population has amounted to 94,000. Between 1894 and 1904 the total German foreign trade increased 66 per cent. in value; trade with the United States increased 59 per cent., with England 38 per cent., with France 28 per cent., and with Russia 23 per cent. The rise in the value of the sea-borne commerce amounted to 75 per cent. In the report it is stated that since 1894 up to 1904, trade with the United States rose from 804,000,000 marks (£40,200,000) to 1,438,800,000 marks (£71,940,000), an increase of some 78 per cent., the increase of the "special trade" (imports for home consumption and exports of domestic produce and manufactures) with the United States being given as 59 per cent. There can be no denying the prodigious growth of German maritime interests in recent years, as an analysis of the figures amply justifies the contention of the German Admiralty to the following effect:—"Every branch of the national industry is deeply interested in the further development of the maritime trade. There is no great German industry that is not dependent upon it in a greater or less degree—in the import of its raw materials, or for the export of its manufactured products, or for both —and thus, that anything which tended to injure or imperil this indispensable factor of the national industry would certainly make itself felt more and more severely, alike as regards the supply for immediate consumption, and as regards the maintenance of employment in individual trades, thereby inflicting a loss in both directions upon the working classes of the empire."

HOME INDUSTRIES.

Coal Mining and Labour Hours.—The final report of the Miners' Eight Hours Day Committee was issued last week. The Committee has not been able to accept the general contention of the coal-owners that a legal eight hours day would mean a serious diminution in the output of coal—nearly twenty-six million tons calculated on that of 1906. But they admit that some diminution of production would follow the statutory reduction of hours, whether introduced gradually or suddenly. Their language is very cautious. In their opinion "the permanent result of a legally restricted day for workers in coal mines, upon wages and employment, is impossible to foretell, but it may be assumed that both will greatly depend upon the disposition of employers and workmen to co-operate to minimise any inconvenience that may arise in the initiation of a new system to the general public, and especially to the manufacturers of heavy goods for export." It is sometimes forgotten that the present practice varies widely, and that if the average be taken the hours are not much in excess of an eight hours day. The average time from bank to bank in all the coal mines of Great Britain is nine hours and three minutes, but the actual hours worked vary from 6 hours 49 minutes in Durham to 9 hours 57 minutes in Monmouthshire for all classes of underground workers. Allowing for customary weekly or fortnightly total stop days the average theoretical week's work all over the country is 49 hours 53 minutes. The Committee find that the reduction of time to a legal eight hours day would make a difference, counting stops and short days running as they are, of 10·27 per cent. The contention of many masters examined by the Committee was that this loss of time ought to be taken as the basis of calculation, and if it be this shrinkage of 26,000,000 tons in the output is arrived at. The Committee do not adopt this view. They find that the actual average of working hours is 13·36 per cent. less than the theoretical, or 43 hours 13 minutes, which gives an average of a little over seven hours for six days in the week. And in the opinion of the Committee, who, however, speak with hesitation, a certain portion of the time now lost would be utilised under a legally restricted day. They consider, too, that other causes would be more or less operative in mitigating the effects of a reduction of the hours of the full working day, among them increased efficiency of labour, improvements in the mechanical equipment of collieries, an extension of the use of labour-saving machinery, and of the multiple shift system, and some increase in the existing flow of outside labour to the collieries. But the Committee agree that some diminution of production would follow a statutory reduction of hours, and that any advance in the price of British coal which did not equally apply to foreign coal would injuriously affect our exports to the nearer ports, a branch of the export trade which amounts to about 14,000,000 tons. Realising the grave possibilities involved in the eight hours day, and the great national importance of the coal trade, the Committee point out that if an eight hours' day is enacted by Parliament it will be desirable to reserve in the hands of the department of the Government controlling mines certain powers of suspension and exemption in the public interest.

The Iron Trade.—The expectation that the early months of the present year would see a large decline in the activity of the iron trade has not been borne out by the event. It was assumed that the demand from America and Germany would be much smaller, whereas it shows a marked increase in both cases. In the four months ended April the shipments to Germany direct amounted to 97,643 tons of pig iron as compared with 52,302 tons in the corresponding four months of 1906, and with 38,423 tons in the corresponding four months of 1905. Some, too, went to Germany through Holland, whose imports were 67,226 tons, as against 59,473 tons in the same four months of last year, and through Belgium, which took 46,820 tons as against 36,127 tons last year. Again, our shipments to America have in the four months of this year exceeded by 161,000 tons the exports in the corresponding period of last year, and this increase follows upon one of 136,300 tons in 1906, as compared with 1905. The Board of Trade returns show that we shipped altogether 670,340 tons of pig iron in the four months ended April 30th last, as against 400,041 tons and 266,648 tons in the corresponding months of 1906 and 1905. Nor is there any reason to suppose that there has been any diminution in the home consumption. Makers have not been able to meet all the demands as required, and the stock of No. 3 Cleveland iron in warrant stores has been reduced to 348,000 tons, a reduction of some 50 per cent. from the highest. Cleveland warrants which in December last fell back to 53s. 6d., have almost recovered all they lost in the depression of a few months ago, the present quotation being 63s. Nor is the revived demand confined to foundry iron. West coast Hematite warrants have been up to 82s. and it is exceedingly scarce. There is a keen demand for it for export and the home demand is larger than ever. There are less than 37,000 tons of it in the public stores of the country and it looks as if it will soon be exhausted. The public stock of raw iron in the United Kingdom is only about 403,000 tons of all sorts, and makers hold little or none. It is said that the orders already booked for America and Germany will run over the summer months, and steel makers in the north have had to pay 85s. per ton for hematite delivered to their works. The immediate future depends largely on America, but there is no signs as yet of declining demand in the United States for either iron or steel. It is long since the iron trade looked stronger.

The Tobacco Trade.—The present position of the tobacco trade is both anomalous and interesting. The consumption of tobacco steadily grows—the

world's consumption has increased by something like 25 per cent. in the last ten years—but the acreage under tobacco has fallen from 1,030,000 in 1902 to 776,000 in 1906, and it is said that 40,000 acres have been abandoned this year. It is with tobacco in an even greater degree than with cotton that dependence upon a single country for supplies causes trouble. The cotton manufacturer, though perilously dependent upon the United States for his supplies, does get supplies from elsewhere—from Egypt, India, &c. But the tobacco manufacturer depends almost entirely upon America. And yet with tobacco as with cotton, many lands are suitable for its growth. British Africa, Ceylon, the West Indies, parts of Australia, all have climatic conditions suitable for growing tobacco, and samples are equal to the American article. The consumption is increasing rapidly. The total home consumption in 1906 amounted to 93,494,000 lbs. as compared with 88,693,000 lbs. in 1905 and 85,502,000 lbs. in 1904, whilst for the first three months of the present year it was 24,034,000 lbs. as against 23,299,000 lbs. in 1906. Naturally with the increased demand and decreased supply there is augmentation in the price of the raw material. It is noteworthy that the 821,823,000 lbs. crop of 1902 was valued at very little more than last year's crop of 629,000,000 lbs. The position is complicated by the growth of Growers' Associations, which aim at controlling the production, and threaten to dominate the markets. The Associations are at open war with the Trusts, and are said to terrorize the farmers. British manufacturers are turning their attention to the possibility of establishing other means of supply, but it must be many years before the commanding position of the American cultivator is seriously menaced. As it is, the manufacturer here finds himself in a very embarrassing position. He hoped for relief by a reduction of the duty on tobacco, or an increase in the moisture limit, but the Chancellor of the Exchequer has proposed no change. The retailer is threatening to raise the price of cigars, and it would seem reasonable to raise retail prices of tobacco, so as to make the consumer pay for the increased cost of the raw material, but in practice it is found difficult to alter what may be called the standard price of 3d. per ounce. The present position of our tobacco trade emphasises the unwisdom of being content to draw the bulk of the raw material from a single and a foreign country. The arguments that apply to cotton in this connection apply, as has been said above, with equal force to tobacco. All the tobacco, as all the cotton, required by British manufacturers can be grown within the limits of the British Empire, but even now the practical steps taken to bring about the desired change are halting and very inadequate.

The Motor-Car Industry.—The only thing the motor-car industry is suffering from at the present time is lack of capital. If capital went into the trade more freely its expansion would become more rapid than it is. But it is very remarkable. Fifteen years ago the foreigner had the market pretty well to himself. The imported motor-car was everywhere—everywhere, that is to say, where the motor-car was to be seen, which was not in very many places; the home-made car was a rarity. The foreigner has still his grip upon the trade, but it is slackening. With each year the demand increases, and the British manufacturer is improving his position as compared with that of his foreign competitor. Last year the British market was worth nearly twelve millions sterling. Of this the foreign manufacturer got nearly four and a half millions, and the British manufacturer about the same, the remainder going to those who buy foreign parts and assemble them. Altogether British trade is estimated to have benefited to the extent of about seven millions sterling. In 1903 the imports of finished cars were roughly of the value of one and three-quarter million sterling; in 1906 they had increased to two and three-quarter million, but in 1906 the growth was only about £200,000, and in the first four months of the present year they show an actual decrease of some £30,000. It is in the "parts of cars" that the foreigner still does a very large business. In the first four months of 1905 he exported to this country motor-cars to the value of £809,659, and parts of cars to the value of £237,735. In 1907 these figures were respectively £812,522 and £879,743. The import of motor-cars was practically stationary; the import of "parts of cars" had nearly quadrupled. The British manufacturer is taking in the year considerably over two millions sterling of foreign-made parts, so that a "British" car has still about 30 per cent. of foreign matter in it, by which it is not, of course, meant that there are no wholly British cars. On the other hand the British export trade is in a very healthy condition. Half-a-dozen years ago the number of British cars outside the United Kingdom was almost a negligible quantity. The foreign make was preferred abroad as here. That remains true, but much less universally true. The exports of British motors in the first four months of 1905 were of a value of only £77,138, and of parts of cars £31,312. In the same months of the present year the figures were respectively £248,705, and £159,380, which indicates substantial expansion. It is to be hoped and expected that as time goes on the British manufacturer will rely less and less upon foreign-made parts. The home factories are working at their utmost capacity. It is expected that there will be 20,000 cars of all grades made in the United Kingdom in 1907. Many more would be made if there were the appliances to make them. There is every indication that the demand will go on increasing, and that the industry will grow to great, even enormous proportions. The shyness of the capitalist is not likely to be long maintained. The distrust born of the memory of the losses of a dozen years ago must give way to the accumulating evidence of the immense possibilities of the motor-car industry. It is indeed a strange anomaly that whilst the public

responds more or less heartily to the invitation of company promoters to put money into gold mines in Siberia and cobalt in Ontario, a young, growing, and promising home industry remains hampered from lack of capital. But it is satisfactory to know that, as shown by the figures quoted, British motor car manufacturers are making their way to the front notwithstanding capital difficulties.

OBITUARY.

W. Martin Wood.—Mr. W. Martin Wood, a well-known Anglo-Indian publicist, died suddenly from heart failure at Weybridge on the 25th inst. in his seventy-ninth year. He joined the Society in 1881 and since 1890 had been an active member of the Committee of the Indian Section, and a constant attendant at the Society's meetings. He resided for many years in Bombay, where he occupied a prominent position as a journalist, first as Editor of the *Times of India*, then as part proprietor of that journal in association with the late General Nassau Lees and the late Mr. Mathias Mull, and subsequently as Editor of a weekly paper, the *Bombay Review*, which he founded. He was a Fellow of the University of Bombay and for some years one of its examiners. He was the author of a work entitled "Things of India Made Plain" and of several political pamphlets. He leaves a widow and three children, a daughter and two sons. One of the latter is a member of the Indian Civil Service.

MEETINGS FOR THE ENSUING WEEK.

Monday, June 3...East India Association, Caxton-hall, Westminster, S.W., 4½ p.m. Mr. R. F. Chisholm, "Indian Pottery."

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, in the Theatre of the United Service Institution, Whitehall, S.W., 7½ p.m. Mr. Cecil A. St. George Moore, "Working Experiences with large Gas Engines."

Chemical Industry (London Section), Burlington-house, W., 8 p.m. 1. Mr. W. A. Davis, "The Nature of, and Changes involved in the Production and Setting of Plaster of Paris." 2. Messrs. W. A. Davis and C. A. Klein, "The Analysis of White Lead." 3. Mr. W. Hansen Rawles, "A Calorimeter for Volatile Liquid Fuels. Specially adapted for Petrol." 4. Messrs. W. P. Dreaper and A. Wilson, "Influence of Temperature of Dyeing on Resolution." 5. Mr. J. K. H. Inglis, "The Loss of Nitre in the Chamber Process. Part III."

Actuaries, Staples-inn-hall, Holborn, W.C., 5 p.m. Annual General Meeting.

Tuesday, June 4...Asiatic, 22, Albemarle-street, W., 4 p.m. Mr. J. F. Fleet, "The Inscription on the Sohgaura Plate."

Royal Institution, Albemarle-street, W., 3 p.m. Professor G. E. Nuttall, "Malaria, Sleeping Sickness, Tick Fever, and Allied Diseases." (Lecture II.)

Alpine Club, 23, Savile-row, W., 8½ p.m.

Anthropological, 3, Hanover-square, W., 8½ p.m.

Wednesday, June 5. Geological, Burlington-house, W., 8 p.m. 1. Mr. S. S. Buckman, "Brachiopod Morphology: *Cincta*, *Eudesia*, and the Development of Ribs." 2. Mr. Herbert Bolton, "A Marine Fauna in the Basement-Beds of the Bristol Coalfield."

Royal Archæological Institution, 20, Hanover-square, W., 4 p.m. Mr. Francis Bond, "The Strange History of the English Parish Church."

Obstetrical, 20, Hanover-square, W., 8 p.m.

Thursday, June 6 Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Prof. A. Dendy and Mr. E. Hindle, "Contributions to our Knowledge of the New Zealand Holothurians." 2. Prof. W. A. Haswell, "Observations on Australasian Polyclads." 3. Mr. C. Tate Regan, "Report on the Marine Fishes collected by Mr. J. Stanley Gardiner in the Indian Ocean." 4. Mr. M. Foslie, "The Lithothamnia of the *Sealark* Expedition." 5. Prof. L. G. Neumann, "Notes sur les Ixodidæ recueillis dans les iles de l'Océan Indien, par Mr. J. Stanley Gardiner." 6. Mr. G. Claridge Druce, *Orobanche Ritro*, and some new varieties of Plants from the Channel Islands."

Chemical, Burlington-house, W., 8½ p.m. Papers by: 1 Messrs. F. Baker and E. C. C. Baly. 2. Mr. F. Tuttin. 3. Messrs. E. P. Perman and J. H. Davies. 4. Mr. I. Smedley. 5. Mr. J. C. Cain. 6. Messrs. S. Smiles and T. P. Hilditch. 7. Messrs. S. Smiles and A. W. Bain. 8. Mr. M. A. Whiteley. 9. Messrs. J. T. Hewitt and N. Walker.

Royal Institution, Albemarle-street, W., 3 p.m. Prof. Sir James Dewar, "Chemical Progress—Work of Berthelot, Mendeleeff, and Moissan." (Lecture III.)

Book-keepers', Cannon-street Hotel, E.C., 7 p.m. Mr. M. Cutter, "Wasting Assets."

African, Criterion Restaurant, Piccadilly, W., 8 p.m. Address by Mr. Shelford.

Friday, June 7...Royal Institution, Albemarle-street, W., 9 p.m. Prof. Sir James Dewar, "Studies in High Vacua and Helium at Low Temperatures."

Art Workers' Guild, Clifford's-inn-hall, Fleet-street, E.C., 8 p.m. Paper on "Painting on Pottery."

Geologists' Association, University College, W.C., 8 p.m. Mr. George W. Young, "The Chalk of Surrey—Part II, the Western Area."

Philological, University College, W.C., 8 p.m.

Saturday, June 8...Royal Institution, Albemarle-street, W., 3 p.m. Sir William White, "The Contest between Guns and Armour." (Lecture II.)

Erratum.—By an unfortunate error the name of Mr. Wedgwood was given as presiding at the last reported meeting of the Applied Art Section (*Journal*, May 24, p. 718) instead of that of Mr. Halsey Ricardo who actually took the chair. The page containing the mistake has been reprinted and will be forwarded to any member on application.

Journal of the Society of Arts.

No. 2,846. VOL. LV.

FRIDAY, JUNE 7, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

APPLIED ART SECTION.

Tuesday evening, May 28, 8 p.m.; SIR JOHN EDWARD BINGHAM, Bart., in the chair. The paper read was "Sheffield Plate and Electro Plate," by SHERARD COWPER-COLES, M.Inst.E.E.

The paper and report of the discussion will be printed in a future number of the *Journal.*

INDIAN SECTION.

Thursday Afternoon, May 30, 4.30 p.m; CHARLES EDWARD HOBHOUSE, M.P., Under-Secretary of State for India, in the chair. The paper read was "Irrigation Colonies in India," by LAURENCE ROBERTSON, I.C.S.

The paper and report of the discussion will be printed in a future number of the *Journal.*

CONVERSAZIONE.

The Society's Conversazione will be held, by arrangement with the Council of the Royal Botanic Society, in the gardens of that Society, Inner Circle, Regent's-park, on Tuesday evening, July 9th, from 9 to 12 p.m.

The central portion of the gardens only will be used. The Conservatory and the Club-house will be open.

The reception, by Sir Steuart Colvin Bayley, K.C.S.I., C.I.E., Chairman, and the other members of the Council, will be held at the entrance to the Conservatory, near the Broad-walk, from 9 to 10 p.m.

Each member is entitled to a card for himself (which will not be transferable) and a card for a lady. In addition to this, a limited number of tickets will be sold to members of the Society, or to persons introduced by a member, at the price of 5s. each, if purchased before the day of the conversazione. On that date the price will be raised to 7s. 6d.

Members can purchase these additional tickets by personal application, or by letter addressed to the Secretary at the offices of the Society, John-street, Adelphi, W.C. In all cases of application by letter a remittance must be enclosed. Each ticket will admit one person, either lady or gentleman, and must be signed by the member applying for it.

Tickets will only be supplied to non-members of the Society on presentation of a letter of introduction from a member.

A programme of the arrangements for the evening will be published in due course.

PRIZE FOR INDUSTRIAL HYGIENE.

The Council of the Society of Arts are prepared to award, under the terms of the Benjamin Shaw Trust, a Gold Medal, or a prize of £20.

The medal, under the conditions laid down by the testator, is to be given "For any discovery, invention, or newly-devised method for obviating or materially diminishing any risk to life, limb, or health, incidental to any industrial occupation, and not previously capable of being so obviated or diminished by any known and practically available means."

Intending competitors should send in descriptions of their inventions not later than December 31st, 1907, to the Secretary of the Society of Arts, Adelphi, London, W.C.

Such descriptions may be sent in under the inventor's name, or under a motto, accompanied by a sealed envelope enclosing the name, as preferred.

The Judges will be appointed by the Council.

The Council reserve the right of withholding the prize or of awarding a smaller prize or smaller prizes, if in the opinion of the Judges nothing deserving the full award is sent in.

PROCEEDINGS OF THE SOCIETY.

APPLIED ART SECTION.

Tuesday, April 30th, 8 p.m.; J. C. WEDGWOOD, M.P., in the chair.

The paper read was—

LUSTRE POTTERY.

By WILLIAM BURTON, F.C.S.

It would be unbecoming in me to commence a paper on Lustre Pottery before the Applied Art Section of the Society of Arts without recalling that it was from this platform, some fourteen or fifteen years ago, that Mr. Wm. De Morgan, our English pioneer in the methods of true lustre decoration, first explained his processes and their results. My reason for reading a fresh paper now, on the same subject, is that during the last fifteen years a great deal has been learnt about the history of the various lustre processes, and great advances have been made by Hungarian, French and English potters in extending and perfecting the various methods of lustre decoration. While gladly acknowledging what the English pottery trade owes to Mr. De Morgan in the way of incentive and experiment, I trust it may be found, when my paper is concluded, that English potters are now prepared to repay the debt by fresh and original work of their own. In considering the subject of "Lustre Pottery" it is necessary to spend some time in a careful consideration of what we mean by the term; for it has been applied indifferently to methods that are old and new, to decorative results that are exceedingly delicate and subtle, as well as to those that are the reverse. On the table before us is assembled nearly every variety of pottery that the most catholic of collectors could bring together under this designation. Here will be found the so-called "copper" and "silver" lustred earthenwares of Staffordshire, Swansea, Leeds and Sunderland, first produced during the latter part of the eighteenth century, so largely manufactured during the first half of the nineteenth century, and now become the spoil of those collectors who despair of attaining to the finest things. Here, too, are the oldest lustres of all, dating back for more than a thousand years when Egyptian, Syrian, or Persian potters discovered a unique method of pottery decoration which was carried round all the countries bordering on the Mediterranean, to which its apogee in the Hispano-Moresque wares of the fifteenth century and the Italian majolica of the sixteenth century. Here, too, are examples of the modern pieces made in imitation of, or in rivalry with these mediæval masterpieces; by Ginori and Cantegalli of Florence; by the Massiers in Cannes; by the Spanish potters of Seville and Manises; by Zsolnay of Pècs in Hungary; by Hermann Kähler in Denmark, and by De Morgan, Pilkington's, Bernard Moore, Maw's and others in England. Here, also, will be found the faint, nacreous, Bismuth lustres, invented by Brianchon of Paris, in 1856, but best known among us, from their use on the once famous Belleek porcelain of Ireland.

What pictures the imagination conjures up under the stimulus of such a string of names. To glance from Old Cairo and Rhages or the Moorish kingdom of Granada, Diruta in its prime and the Gubbio of Maestro Giorgio, to the days of Wedgwood in England, and on to our own times, is enough to take one's breath away. But the art of the potter has always been most conservative of its past, and in such an art, it need occasion no surprise to find the latest and youngest experimenters among us eager to emulate the successes achieved centuries ago by men whose very names are forgotten; but whose works survive "Like good deeds in a naughty world."

Even a cursory glance at such a collection, the like of which has probably never been gathered together on a lecture-table before, shows that the one feature which all the "Lustres" have in common is a shining metallic quality of surface, which marks them off from every other kind of pottery decoration. Though this quality is more or less manifest in all the decorations of this class produced during the last thousand years, let us study it first in the so-called copper and silver lustres of our every-day English pottery, introduced a little more than a century ago. Here, at all events, the metallic quality is developed to the utmost, for pottery covered all over with such lustres as these, recalls at once the characteristic appearance of vessels shaped in metal, and there can be no doubt that the Staffordshire and other English potters of the late eighteenth and early nineteenth century, thought they had discovered a delightfully simple method of making their pottery look like metal; for they shaped their vessels in exact imitation of those of the silversmiths and goldsmiths of the period; and as

they were mechanically-minded people they modelled their mugs, jugs, sugar-boxes, teapots, and candle-sticks as accurately as possible on the popular Sheffield plate of the day. All unconsciously, they seem to have been following the example of the first inventors of the lustre decoration, for there is no doubt, in my mind, that the potters of Egypt, Syria, and Persia, who made the first "lustres," in those far-off centuries when the East was still the cradle of the arts and sciences, also hailed their invention as a brilliant discovery that enabled them to make pottery look like gold.* We are so accustomed in these days to see, on every hand, pottery decorated with gold fired to the glaze that it is difficult to realise what a modern invention the gilding of pottery and porcelain really is. Gold fired on to the surface of glazed pottery appears to have been unknown to all the great potters of the Middle Ages. I am inclined to the opinion that the Chinese and Japanese may have taught its use to Europeans, and there is ample evidence that its use in Europe is scarcely earlier than the middle of the eighteenth century.† Where leaf gold had been applied to the surface of tiles or vases before this period, it appears to have been merely attached by japanners' size, and must, therefore, be regarded as an exotic decoration, for we must refuse to consider anything pottery decoration which has not been fired.

It is all very well to grind up leaf gold with a small quantity of a soft flux, which would fix it to glazed pottery on refiring at a low temperature, but the latter part of the eighteenth century, which witnessed such an outburst of experimental work in pottery, was also the period of the fresh departure in natural science which laid the foundation of modern chemistry. Gold was being experimented with in many ways, for the old search for the philosopher's stone had only taken a fresh direction, and before the end of the century it was found that gold could be applied to pottery by mixing a solution of the metal in *Aqua Regia*, with thick oily or resinous fluids, so that when a coat of the mixture was carefully laid over the pottery and fired at a low heat a shining golden deposit was immediately produced without any further trouble. So far as we can learn, it was some unknown experimenter in the Staffordshire potteries who first made this discovery, and during the last decade of the eighteenth century the method was in extensive use in England.*

It is interesting to recall, too, how soon the newly-discovered metal platinum was brought into use for the same purpose. Just as it was found that gold-chloride solution diffused in a thick oily menstruum would furnish a coat of shining gold, one of the first industrial uses of platinum was its application, in a similar way, to produce a shining deposit of platinum on crockery, which went by the common name of silver lustre, because of its resemblance to that metal in appearance and because the name "platinum" would have meant nothing to the ordinary person at that period. I always like to imagine, myself, that the introduction of these shining metallic deposits of gold and platinum owed much to our greatest English potter, Josiah Wedgwood, for from his intimate connection with the best scientific men of his day he is likely to have learnt about such a substance as platinum before any other Staffordshire potter, and Professor Church has informed us that he obtained some information on the subject of

* Mr. Henry Wallis has suggested that, as it was considered derogatory in Byzantium, during her prosperous days, to eat or drink from vessels of other metals than gold or silver, in her declining years, when the precious metals had been gradually absorbed, the potters would copy designs from the gold or silver smith, and the lustred ware became a cheap but showy substitute for the precious vessels which had previously enriched the Credenza.

In Spain, too, the old lustred ware is known as "Dorada," *i.e.*, "Gilded," and Ibn-Batuta, the famous Arab geographer and traveller, writing in 1350, speaks of the ware made at Malaga as the "Gilt pottery or porcelain which is exported to the most distant countries."

† When the King of France, Louis XV., became financially interested in the porcelain factory at Vincennes, shortly before its removal to Sèvres, it is recorded that a large sum of money was paid to a Benedictine friar, named Hippolite, for the secret of gilding decoration; and yet Vincennes appears to have been the first European factory that used gold at all extensively in the decoration of porcelain, and it was at that time not used on pottery or faience at all. The famous Wedgwood appears to have had great difficulty in acquiring a knowledge of how to apply fired gold to pottery, and almost his only patent has reference to an imperfect method of gilding.

* Simeon Shaw, in his "History of the Staffordshire Potteries," published in 1828, ascribes the invention to John Hancock, though he also mentions a decorator named Hennys as having been concerned in its introduction. But Shaw was a most uncritical and unreliable purveyor of gossip; he frequently published contradictory statements, and personally I attach very little importance to his statement. It is a matter of painful interest to an English potter to realise that this process invented in England led directly to the production of liquid gold, which is now sold by German firms to the Staffordshire potters to the amount of probably £100,000 per annum. On a small scale it is the story of the analine industry over again: The Englishman acting as inventor, and then from want of sufficient scientific knowledge, losing the trade to the better trained German.

lustre from Dr. John Fothergill, as early as the year 1776. Certainly, too, Wedgwood was one of the potters who made extensive use of these gold and platinum lustres, though other Staffordshire potters were active in the same field in the late years of the eighteenth century, and the method seems to have been pretty widely spread, as it was soon practised at Swansea, Leeds and Sunderland.

There are many examples exhibited here to-night which enable us to realise what these English lustres were like. The deposit of metallic platinum is always dense and metallic, so that vessels coated with it shine almost like silver, hence the unfortunate name of "Silver" lustre that has been generally given to it. The gold lustre is sometimes quite as dense, though we often meet with it used so thinly that the colour of the pottery on which it has been applied is an important factor in determining the colour effect. On white or cream colour ware if the lustre is thinly applied it gives only a pale purplish stain, with a faint golden sheen, but on red pottery or where it is thickly applied it may look like gold, copper or bronze. Sometimes copper was added to the gold to produce a darker and more bronze-like effect.

If we were to consider the production of a metallic surface on pottery as the true aim of lustre, then this English pottery of the late eighteenth and early nineteenth century must be regarded as the most perfect "lustre" pottery ever made, for nothing could exceed the evenness and regularity of its shining metallic surfaces.

The metallic quality of surface is, however, only one feature of the finest lustre effects, and neither the most important nor the most beautiful one. If we examine examples of the fine lustres of the Persian, Spanish or Italian potters, we shall find that the decoration, however strong and metallic it may be in certain lights, is softened and beautified by a wonderful play of iridescent colour, so that it assumes something of the changing quality of the inside of a pearl shell, or is diversified by a play of brilliant colour like a soap-bubble, or the feathers of a peacock's tail. But in these qualities the metallic films of gold and platinum are entirely deficient, for they present nothing but a dazzling unbroken surface like a sheet of pure metal. I must assume that everyone knows now-a-days, that these brilliant interference colours—soap-bubble colours one might well call them—of true lustres, are due to the presence of thin films, and the process which gives us the heavy metallic deposits of gold and platinum are opposed to the production of metallic films sufficiently thin to be iridescent. The iridescent films are most easily produced from other metals such as bismuth, silver and copper; precisely because these metals are capable of being tarnished or oxidized in air, while gold and platinum are not. I have here, for instance, thin sheets of the four metals—gold, platinum, silver, and copper; one of these sets has been kept free from action, while the other set has been exposed merely to the action of damp air and gentle warmth. You see at once that the gold and platinum retain their brightness unimpaired; the copper and silver, while they have lost something of their original brightness, have acquired instead, a play of iridescent colour.

The only form of pottery decoration which in my opinion ought to be called lustre, is that which exhibits, besides the metallic sheen, this play of iridescent colour, shewn here on thin sheets of copper and silver, and it would be much better, in my opinion, if our so-called English lustres, made with a basis of gold or platinum, were described as "plated" or "metallised" pottery, so as to avoid the confusion, into which many writers and collectors have fallen, of treating these not very artistic products as if they belonged to the same category as the splendid lustres of old time.

I have said that the problem of making true lustre pottery, is that of obtaining films of metal, generally of copper and of silver, on a fired pottery glaze in sueh a way that the metallic deposit has iridescent colours upon it. The gold and platinum deposits can be obtained with the greatest ease by firing the article coated with the resinous or oily pigment in an ordinary muffle furnace at a clear red heat, for the two noble metals are reduced to the metallic state in the presence of carbonaceous matter; and, when once deposited, they remain absolutely untarnished by the air, so there is no need to exclude the atmospheric oxygen from the kiln. But with silver and copper the case is quite different, for these metals are not so easily reduced to the metallic state as gold and platinum, and even when they are reduced they very readily oxidise and turn black at a red heat unless care is taken to exclude all oxygen. Fortunately, however, silver and copper are capable of forming volatile compounds at a comparatively low temperature, especially in the presence of reducing gases, such as hydrogen, coal-gas, and carbonic oxide; and

these volatile compounds will penetrate or stain into any ordinary pottery glaze, giving a characteristic yellow stain with silver, and a magnificent red stain with copper. Moreover, if the firing and the action of the reducing gas be continued long enough, the yellow or red stains become deeper and deeper in colour, and they finally develop an iridescent film on their surfaces exactly resembling the iridescent films on the sheets of tarnished copper and silver before you. Described in this way, the process of true lustre seems simple enough, yet in actual practice it proves to be one of the most delicate and difficult of all the methods of decoration yet used in connection with pottery, and this difficulty and uncertainty is probably the explanation of the curious fact that after the process had reached a high pitch of excellence in Spain and in Italy it fell into almost complete disuse in Europe, and has only been revived since about 1860.

Where the method was originally invented is by no means certain, but the earliest examples that have been found are those dug up on the site of the city of Rhages, once the capital of the Persian Empire, which was destroyed in the thirteenth century, and those which have been recovered from the rubbish mounds of Fostat, near Old Cairo, by the labours of Mr. Henry Wallis and other Orientalists. In the present state of our knowledge we can only say that the process was probably invented by Egyptian, Syrian, or Persian potters working for the Arabs, and that, in common with many other Oriental arts the knowledge of it was carried through the various countries which the Arabs conquered or over-ran. The process was extensively adopted by the Spanish potters, especially by the Moorish potters of the south and east of the peninsula, and afterwards conveyed to Italy either by Moorish potters themselves or by daring Italian potters who had penetrated into Moorish places in Spain or into the potteries of the East and learned the secrets of the process.*

Although the methods of making lustre used in the Middle Ages appear to have had one common origin, it is interesting to notice how each race of potters developed the methods in their own way so as to arrive at strikingly different results. To consider what is probably the oldest lustre first, that which is commonly known as Persian lustre, and of which there is a magnificent display in the Victoria and Albert Museum, it is interesting to notice that the silver appears to have predominated in the lustreing material, for the films are generally yellowish or brown, the actual red lustre given by copper being comparatively rarely met with. What is so noticeable, however, in the Persian lustre, is the brilliant iridescence and the effect of the metallic rêflet with its predominance of green and rosy tints that are less noticeable in the mediæval lustres made in Europe.

In the Spanish lustres, on the other hand, copper was much more largely used, and everyone must be familiar with the heavy embossed dishes coated with the strong metallic lustre of characteristic copper colour. Silver lustre was, however, used to a considerable extent in Spain, especially in conjunction with patterns painted in underglaze blue. There is one pale brassy tint of Spanish lustre which appears to have been made at Valencia, or in that neighbourhood, and which is almost as characteristic as the glorious copper-red with a brilliant metallic sheen, which was made at Manises, Malaga, and elsewhere in the south. No doubt the English lustres we have already discussed, and dismissed, make a fair approximation in effect to some of the coarser and more metallic kinds of Spanish lustre, but there is the fundamental distinction that the Spanish lustre, strong and metallic as it is in appearance, has at the same time a beautiful play of iridescent colour upon it.

When the Italians learnt the art of lustre making, probably sometime in the fifteenth century, they appear to have first of all contented themselves with making only silver lustre, and the beautiful plates, dishes and vases which are commonly attributed to Diruta and which now have the most beautiful iridescence, like mother-o'-pearl, upon them, form probably the high-water mark that the silver lustre process ever reached, until the present time.

Although there is ample evidence that the Italians were great collectors of the lustred wares of Spain, and a great many of the specimens of Hispano-Moresque lustre ware in modern collections have been obtained from Italy and not from Spain, the Italian use of copper lustre is remarkably different from the use made of it by the Spanish potters. Even where strong copper lustre was used alone by the Italian potters, as in the case of the three famous Gubbio

* Professor Langton Douglas states ("History of Siena," p. 451) that a Sienese potter, Galgano di Belforte, went to Valencia and, disguising himself in mean apparel, learnt the secret of lustreing pottery and then returned with his knowledge to Siena in 1514.

pharmacy jars in the Victoria and Albert Museum, the lustre is far less metallic than the Spanish, while the beautiful ruby-red stain, which is given by the penetration of the copper vapours into the glaze, is much more pronounced. It has been suggested by many writers that the ruby-red was a secret of the potters of Gubbio, and that all the pieces of it which occur have been lustred in that town. We have no means of knowing whether such a belief is well founded or not, but it is certain that the Gubbio potters made great use of the ruby stain, and that in fact, they used it as much for its beauty of colour as for its lustre quality.

At a first glance it would seem as if all these different varieties of lustre, the Persian, the Hispano-Moresque, and the Italian, must be due to some essential difference in the methods or materials used in the different countries, but the experience gained at our own works convinces me that the variations are not any greater than would naturally follow from pursuing exactly the same methods in the haphazard way in which we know the potters of the Middle Ages worked, and that the greatest factors in determining the results were the nature of the glaze and the intensity and duration of the firing.

We possess no information as to the methods used by the originators of the lustre process in the East ; but, fortunately, we have ample evidence left to us, almost accidentally as it may seem, which enables us to reconstruct with absolute accuracy the mixtures and the methods that were used by the Spanish and the Italian potters of the Middle Ages, and as this information never seems to have been properly understood by our English potters and writers, perhaps I may be forgiven for dwelling on it with a certain amount of detail. There is preserved among the treasures in the library of the Victoria and Albert Museum a manual of the Italian potter's art of the sixteenth century, in a manuscript written in 1548 by the "Cavaliere Cipriano Piccolpasso Durantino," as he signs himself on the title-page. The greater part of his interesting treatise is taken up with an account of the methods of pottery making and decorating used in Italy in his time ; but in a supplement he gives us an account of the lustre process, which he did not practise himself, and says : "I know well that it is painted over finished work" (by which he means pottery already decorated in colours and glazed) ; "this I have seen in Ugubio, at the house of one Maestro Cencio.* These finished pieces are subsequently touched with the lustre pigment, composed as follows :—

Rosso Da Majolica.

		A	B	C
Terro Rosso	oz.	3	6	6
Bolo Arminia	,,	1	0	0
Feretto di Spagnia	,,	2	3	3
Cinabrio	,,	0	3	3
Argento Calcinato	,,	0	0	1

"To the second mixture (called 'majolica d'oro') add a *carlino* of calcined silver, grinding them all together (this is C), then place them all in a pipkin, with a *quattrino* (a small copper coin) and fill with red vinegar, in which they are to macerate until the latter is all consumed ; it is then again ground up with more vinegar, and applied with a brush to those parts of the design to be lustred. The process of firing differs from the former one, inasmuch as the pieces are not enclosed in saggers, but are exposed to the direct action of the flames.

"The furnace is differently constructed, the fire chamber square in form, having no arched roof pierced with holes, but only two intersecting arches of brick to support the chamber above, the four corners being left as openings for the free current of the flames. Upon these arches is placed a large circular chamber or vessel, formed of fire-clay, which fits into the square brick structure, touching at the four sides, and supported on the intersecting arches beneath, but leaving the angles free. This inner chamber is pierced in all directions with circular holes, to allow the flames free passage among the wares. The method of building these furnaces is kept guarded, and it is pretended that in it and the manner of firing consist the great secrets of the art. The *scudelli* are packed with the edge of one against the foot of another, the first being supported on an unglazed cup. The furnaces are small, only from three to four feet square, because this art is uncertain in its success, frequently only six pieces being good out of a hundred ; true the art is beautiful and ingenious, and when the pieces are good they pay in gold.

"Only three varieties are produced, golden, silver, and red ; other colours can only be given by the other method (*i.e.*, underglaze painting). The fire is increased gradually, and is made of *palli* or dry willow branches ; with these three hours firing is given ; then, when the furnace shows a certain clearness, having in readiness a quantity of dry broom (*ginestre o vogliam spartio*) cease using the willow wood, and give an hour's firing with this ; afterwards, with a pair of tongs remove a sample from above. Others leave an opening (*vedetta*) in one of the sides, by which a sample or trial, painted on a piece of broken ware, can be removed for examination, and if it appears sufficiently baked, decrease the fire.

"This done, allow to cool, then take out the wares

* This was the son of the famous Maestro Georgio.

and allow them to soak in a lessive of soap-suds, wash and rub them dry with a piece of flannel, when with another dry piece and some ashes (of wood) give them a gentle rubbing, which will develop all their beauty.

"This is all, as it appears to me, that can be said about the majolica, as also about the other colours and mixtures that are required in this art."*

As Piccolpasso fortunately for us illustrated his manuscript with a number of pen drawings, and among these were rude representations of the furnaces used for firing the lustres, I am able to show you how the firing was conducted.

[Here followed some lantern slides showing the style of kiln used in firing the sixteenth century Italian lustres with explanations on the process.]

It will be noticed that although Piccolpasso had no experience in the actual production of lustre decoration, he states that:—

"The method of building these furnaces is kept guarded, and it is pretended that in it and the manner of firing consist the great secrets of the art . . . . because this art is uncertain in its success, frequently only six pieces being good out of a hundred. . . . . true the art is beautiful and ingenious, and when the pieces are good the pay is gold."

Piccolpasso appears to have been doubtful himself whether the Gubbio potters had really told him their secrets and whether they were not pretending when they said that the real secret consisted in the construction of the kilns and in the method of firing. Singularly enough Maestro Cencio, from whom Piccolpasso apparently derived the information, had told him the perfect truth; the mixtures and the methods are quite correct, and so is the statement that in the method of building the furnaces and conducting the firing resides the secret of the art.

Just as we have this detailed information about the Italian processes, Senor Riano was fortunate enough to find in a manuscript in the British Museum a detailed account of the preparation of the Spanish materials which he published in his handbook of the Spanish arts written for the South Kensington Museum more than twenty years ago.†

"Count Florida Blanca, wishing in 1785 to establish at Madrid a manufactory of metallic-lustred ware, had the following report on the actual state of the industry sent to him from Manises with full details of the manner in which it was required to be carried out.

"After pottery is baked, it is varnished with white and blue, the only colours used besides the gold lustre; the vessels are again baked, if the objects are to be painted with gold colour, this can only be put on the white varnish, after they have gone twice through the oven. The vessels are then painted with the said gold colour and are baked a third time, with only dry rosemary for fuel.

"Five ingredients enter into the composition of the gold colour; copper, which is better the older it is; silver, as old as possible; sulphur, red ochre, and strong vinegar, which are mixed in the following proportions: of copper three ounces, of red ochre twelve ounces, of silver one *peseta* (about a shilling), sulphur three ounces, vinegar a quart; three pounds (of twelve ounces) of the earth or scoriæ, which is left after this pottery is painted with the gold colour, is added to the other ingredients.

"They are mixed in the following manner: a small portion of sulphur in powder is put into a casserole with two small bits of copper, between them a coin of one silver *peseta*; the rest of the sulphur and copper is then added to it. When this casserole is ready, it is placed on the fire, and is made to boil until the sulphur is consumed, which is evident when no flame issues from it. The preparation is then taken from the fire, and when cold, is pounded very fine; the red ochre and scoriæ are then added to it; it is mixed up by hand, and again pounded into powder. The preparation is placed in a basin, and mixed with enough water to make a sufficient paste to stick on the sides of the basin; the mixture is then rubbed on the vessel with a stick; it is therefore indispensable that the water should be added very gradually until the mixture is in the proper state.

"The basin, ready prepared, must be placed in an oven for six hours. At Manises it is customary to do so when the vessels of common pottery are baked; after this, the mixture is scratched off the sides of the basin with some iron instrument; it is then removed from there, and broken up into small pieces, which are pounded fine in a hand-made mortar with the quantity of vinegar already mentioned, and after having been well grounded and pounded together for two hours, the mixture is ready for decorating. It is well to observe that the quantity of varnish and gold-coloured mixture, which is required for every object, can only be ascertained by practice."

It will be observed that in this manuscript, while we have a most careful and accurate description of the method of making the lustre pigment, nothing is said of the manner of firing; but there can be no doubt that the Spanish lustres were fired in similar kilns and in a very similar way to the Italian lustres, except that probably the firing was more prolonged.

* In this translation I have followed the excellent version of Mr. Drury Fortnum in his treatise on Italian majolica.

† I am informed by Mr. A. Wenger, of Hanley, Staffordshire, that original of this manuscript is now in the Royal Archives at Madrid.

Mons. L. Franchet,* a well-known French ceramic chemist, has been working on the subject of these old lustres concurrently with but quite independently of my brother and myself, and he has published a re-calculation of these lustre pigments into modern chemical formulæ, which supports the following table of them which I have prepared, though our figures are not identical, which is hardly to be wondered at when dealing with such uncertain substances:—

	Hispano-Moresque.		Piccolpasso* A	B	C
Red clay (red ochre, &c.)	10	..	4	6	6
Sulphide of copper . . .	4	..	2	3	3
Sulphide of silver	1	..	—	—	—
Cinnabar	—	..	—	3	3
Calcined silver	—	..	—	—	1

Mr. De Morgan and some other writers have fallen into a considerable error in the treatment of these old recipes, for Mr. De Morgan says that Piccolpasso's recipes are for the diluent clay only, as he says nothing about either copper or silver, and he surmises that Piccolpasso had been hoaxed by Maestro Cencio.† Referring to the Spanish recipes, Mr. De Morgan says that the pigment contains sulphur, and he assumes that it is entirely different in character from the recipes given by Piccolpasso. I am at a loss to understand these statements, because, as I have shown, the Italian recipes are perfectly accurate, and mention has been made both of silver and copper, while the Spanish recipe contains no sulphur as such. The description tells us carefully that all the excess of sulphur must be burnt off in preparing the pigment, and all that is left is a mixture of the sulphides of copper and silver, which is one of the simplest and best compounds that could be used for the purpose. The idea that because sulphur was used in preparing the Spanish pigment the lustre had something in common with the English gold lustres, made by pouring a solution of gold chloride into balsam of sulphur, was quite devoid of foundation.

* Those who are interested in this subject will find an admirable *resumé* of Mons. Franchet's views in the French Journal "La Ceramique" for April, 1907, which repeats in somewhat fuller detail a paper which appeared in the Comptes-Rendues of December, 1905.

† Mr. De Morgan apparently translated Piccolpasso's "Feretto di Spagnia," as "iron-earth" or "iron ore," but in the famous treatise on glass manufactured by Antonio Neri, published at Florence in 1640 (De Arte Vitraria), the preparation of "Feretto de Spagnia" is carefully described, and the substance is sulphide of copper.

It would be beyond the scope of this paper to enter into any description as to why the lustre process, having been so perfectly acclimatised both in Italy and in Spain in the sixteenth century, should afterwards have fallen into such complete disuse, that Brongniart, when he was writing his great treatise on the ceramic arts in 1840, knew nothing of the ancient practice and could only make some not very sensible suggestions as to how the effect might have been obtained. But although the old lustre process has been forgotton, except probably here and there in remote Spanish or Italian villages where the traditional methods still lingered, the idea of lustre was still present in men's minds, as we have seen from the efforts made in England to obtain effects by the use of gold.

The next step forward was taken about 1856 when a chemist, Brianchon, of Paris, patented a process in France, Germany, England, and other countries for producing beautiful pearly, iridescent effects by the use of salts of bismuth. Brianchon's process was an exceedingly simple one, for he took the thick oily "balsam of sulphur," which was used as the basis of the gold lustre, and dissolved in it crystals of sub-nitrate of bismuth; when this fluid was finely spread over a white glaze, and fired in the ordinary way in a muffle kiln at a very low red-heat with free access of air, it left behind an exquisitely thin film of the bismuth compound which was quite transparent, and gave a very brilliant display of iridescent colours, recalling those on the inside of an oyster shell. Thus Brianchon's lustre achieved a remarkable success for a short time, and no doubt many of you will be familiar with its appearance on the well known Belleek porcelain. Interesting as this peculiar lustre is it cannot be looked upon as a substitute for the genuine lustres we are here to discuss. In the first place the film has no colour of its own, and the iridescence, though delicately beautiful when seen near at hand, is too faint to be really effective. Moreover, the effect was obtained at so low a temperature that the lustrous film is soon destroyed in use, and I have known several pieces of this ware that soon lost their lustre by ordinary washing and cleaning.

As I have already said, there is little doubt that although the true lustre process as used in Italy and in Spain had fallen into disuse the knowledge of the composition of lustres appears to have lingered on. We have evidence that in Spain this was so, because there are modern

Spanish pieces still being made by descendants of the old Moorish potters. Here, for instance, is a dish made by Senor Juan Castan, of Manises, in 1865, and I am informed by my friend, Mr. Wenger, who had this piece from the potter himself, that this family had continued the lustre process on peasant pottery, without interruption, from the Middle Ages.

The actual revival of our own time appears to have been due to an apothecary of Gubbio named Carocci about 1860, and several workmen who had been employed by him went to the Ginori factory in Florence, to the Cantegalli factory, to the factories in the South of France, and, about 1870, one of them named Pietro Gaz or Gazzi was in the Staffordshire potteries endeavouring to sell his secrets. He experimented both at the works of Messrs. Wedgwood and those of Messrs. Minton, and I have seen specimens of the pieces he made there, as well as the manuscript note-books he left behind him. The recipes he gave were perfectly accurate and to all intents and purposes were the same as those given in Piccolpasso's manuscript, but his directions for firing were entirely misleading. In any case he was not successful in the production of saleable pieces, and he left the district early in the seventies. About that time William De Morgan worked out a process quite independently for himself and was the first English potter, so far as I know, who ever made true lustres. Everyone here is doubtless familiar with the splendid pioneer work done by Mr. De Morgan, and as he has already ex-explained his work before the Society of Arts I may be excused for not mentioning it in fuller detail now. I understand that Mr. De Morgan's processes were carried by some of his workmen to other English potteries, and lustres of the same type have since been made by Messrs. Maw and Co. of Benthall, Messrs. Craven Dunnill and Co. of Jackfield, Messrs. J. C. Edwards of Ruabon, and Messrs. Carter and Co. of Poole. Examples produced by each of these firms have been kindly lent to me for exhibition and will be found in the show-cases in the room.

It cannot be said that the practice of these English makers added anything fresh to the development of the lustre process. The methods used by Mr. De Morgan and by the other English potters, were practically the same as those already described, except that I understand china clay was used instead of red earth or red ochre for mixing with the salts of silver and copper to make the lustre pigment. The firing process was also conducted a little differently, for instead of the flames passing through the muffle containing the lustre pieces these were generally fired in a closed muffle of the ordinary type, and when the temperature had been obtained sawdust or wood shavings or dry gorse was thrust into the lower part of the chamber beneath the ware. When this had flared up sufficiently to make a thick smoke in among the pieces, the opening was closed so that the ware to be lustred was given a dense smoke bath of greater or longer duration. In this case, of course, the particles of carbon in the smoke, and no doubt some of the hydrocarbon vapours, produced by the imperfect combustion, act as the reducing agents, and by drawing out, from the apertures in the top part of the kiln, broken shards which have bands of the lustre pigment painted on them, the development of the stain and the reducing film may be watched, and when the fireman deems that the process is complete, the fires are withdrawn, and the process is stopped. Although, as we have said, the practice of the English potters added little or nothing to the lustre process, it must be said that Mr. De Morgan and the other makers produced a type of red lustre which was rather novel, and often exceedingly beautiful, because the ruby stain was generally highly-developed on the pieces and with a much less metallic effect than the Spanish, so that the colour remained more transparent. I do not consider that they have been nearly so successful in the development of the silver lustre effects. Besides this, one gladly recognises that Mr. De Morgan's designs, though based on those of Oriental and Italian potters, have a character of their own, and he undoubtedly set the fashion with a style of design in many respects superior to what had been seen on English pottery before. I must not forget to mention, too, that Messrs. Maw and Co. produced some lustre vases, dishes and tiles from designs by Walter Crane and Lewis F. Day, which were both striking and beautiful.

The next departures in the development of the lustre process were made by the Massiers of Cannes, and especially by M. Clement Massier, some of whose fine pieces are exhibited here. Mr. Massier soon departed from the scheme of lustre designs on a white ground or an ornament left in white on a ground of underglaze blue, and began to lustre the glaze itself. For this purpose he took soft

glazes containing copper dissolved in them, and, after etching the surface with a pattern, or etching away the ground from about the pattern, with hydrofluoric acid so as to get both bright and dull surface of glaze on the same piece, he refired the piece in a smoke kiln at the lustreing temperature, and obtained in this way a great variety of novel and striking effects. His processes were still further diversified by painting silver and copper lustre pigments on the surface of glazes which could themselves be lustred, and so he introduced a number of effects which were altogether novel and in some respects beautiful. Unfortunately, from my point of view, Massier and his artists were rather devoid of taste. The forms of their vases are distinctly ugly, the shapes recalling the shapes of metal rather than of clay, while the ornament itself is generally too naturalistic for the process, and although the Massier processes often gave very beautiful pieces the feeling remains that the beauty was frequently the result of accident rather than premeditated design. Various artists have from time to time left M. Massier's works, and carried his processes to other factories, but without the production of anything really new.

The next important departure was made by the firm of Zsolnay, of Pècs in Hungary, who made a speciality of the ruby stain without lustre, like that produced by Maestro Giorgio at Gubbio in the sixteenth century. In addition to this, which was the most striking of their new departures, they produced a great variety of admirable designs of a quasi-oriental character based on Byzantine, Persian, and Indian motives, in silver and copper lustres on grounds of blue, purple, brown, and white. The display made by this firm at Paris in 1900 was one never to be forgotten, not only for the beauty of many of the individual pieces shown but from the delicacy of the designs and the mastery of the whole process that was implied by such a display. Since 1900, however, the Zsolnay pieces appear to have fallen off in this artistic character; many of the delicate designs are no longer seen in this country, and their pieces too frequently exhibit a garish display of powerful red - copper stain, with a bright metallic green lustre, a colour scheme that, to our English ideas, is barbarically repellant.

During the last year or two fresh attention has been paid to the lustre process in this country, especially by Mr. Bernard Moore, the famous Staffordshire potter, and ourselves, and although we are the best of friends and freely criticise each other's work neither of us knows the process used by the other. I should like to say that I consider many of Mr. Moore's effects not only novel in themselves but strikingly beautiful. Of the work made at our own factory I cannot speak, but there is a collection of it here to-night which may, I hope, speak for me.

I should like, however, to give a short account of the processes that we have found best adapted to the purpose, and such an account may help to clear up certain misconceptions that have been prevalent with regard to the old lustre processes. I have described the old methods and materials as accurately as I can, and I have stated, as the result of my experience, that they will produce perfect and beautiful lustres. There is, however, no reason, so far as I can see, for adopting the old Spanish or the Italian methods for preparing the lustre mixture. All that is necessary is that some compound of copper or of silver, or mixtures of the two, should be mixed with a suitable proportion of some inert substance, which can be either china-clay, or any ordinary red brick clay. It is necessary that the copper or silver compound used shall be pure and of standard composition. The sulphides, oxides or carbonates of the two metals answer perfectly, and they are, on the whole, to be preferred to the chlorides or the nitrates. The mixture of clay and metallic salt having been carefully ground, like any other pottery pigment, can be painted over the fired glaze, using any ordinary potter's medium, that is they can be painted on with turpentine and fat oil, with sugar and water, or, as the mediæval potters did, with vinegar. I believe that generally the Continental practice is to use vinegar, and the Italians profess that no other medium works so well, but that does not agree with our experience. The pattern having been frankly painted on, the pieces are then placed in a special muffle kiln and fired, and that is where, I believe, the most important part of the whole process resides, and where, I think, we have probably made the greatest advances. I may recall Piccolpasso's statement that the firing of the lustre was a very uncertain process, and that often not more than six pieces were good out of a hundred; and I have understood from Mr. De Morgan that, at times, his experiences were almost as disheartening. When we consider the rude and elementary methods used for firing lustre, this is hardly to be

wondered at, because such firing must often have been irregular, with the result that the smoking would be equally irregular too. The first necessity is to design a muffle kiln that can be raised to an even temperature throughout, but that only necessitates careful kiln construction. The next point is the correct ascertaining of the requisite temperature, because the lustreing process takes place at a red heat so low as to be barely visible, and the ordinary trials on which a potter relies for judging the temperature of his kilns are useless, but with a well-constructed kiln and a competent fireman there should be little difficulty in obtaining the proper temperature in a great proportion of the kiln.

The next point is the admission of the reducing gases or smoke. Here again, perhaps, I may clear up a little misapprehension. It has been suggested by many writers that the peculiar beauty and softness of many of the old lustres may have been due to the special fuel that was used for the purpose, and some will have it that broom or rosemary is the only fuel which will produce a suitable smoke for the parpose. Such an idea is quite erroneous. Certainly, if broom is plentiful, it produces a very nice and not too dense smoke; but any kind of wood will produce equally good results, or, as Mr. De Morgan stated, sawdust or shavings will answer the purpose just as well, while even resin and pitch could be used. As a matter of fact, the reduction is much more evenly effected by the use of reducing gases, such as a mixture of carbon-dioxide and carbon-monoxide, or ordinary illuminating gas. For this purpose the muffle is best constructed in iron with tapped pipes passing into and out of the kiln to allow for the slow passage of a current of the particular gas to be used. Then when the correct temperature has been reached, after sweeping out the small quantity of air that remains by a current of carbon-dioxide, carbon-monoxide or coal-gas can be admitted and the reduction takes place very regularly and steadily. It will be found, however, in practice, that it is very necessary to arrange the pieces in the kiln in such a way that the currents of gas are diffused as uniformly as possible through the kiln from top to bottom and from side to side; indeed it is astonishing how difficult it is to avoid the setting up of currents of gas in given directions, so that the pieces are more quickly reduced on one side than on the other. In our own case the temperature, intensity of the reducing gases, and the rapidity of current are so perfectly under control, that our kilns are hermetically sealed through the whole process, and we never draw a trial of any kind.

When the pieces are taken out of the kiln they are still coated with the lustre pigment, which can, however, be easily scrubbed away with soap and water, unless the temperature has been too high, when it will be found that the lustre mixture has been fused into the surface of the glaze, leaving a nasty grey non-metallic film and a spoilt piece of ware.

Certain very interesting effects have been brought to light in the course of our work to which I may direct your attention, particularly as they do not seem to have been mentioned before in any description of the process.

The first effect of the lustre firing is apparently to volatilise some compound of silver, which penetrates into the glaze, giving it a yellowish stain, and this yellow stain is produced long before there is any stain from the copper compound, and whether the kiln atmosphere is reducing or not. On the contrary no stain appears to be developed from the copper until the atmosphere is powerfully reducing, and then the red stain makes its appearance and slowly deepens during the whole time of reduction. Moreover, if the firing is conducted for a long time these volatile stains of silver and of copper slowly spread over the whole of the glaze surface, so that if you take a perfectly white vase and cover its surface fairly well with a foliated pattern in silver or in copper the ground of the piece may become entirely yellow or red as the case may be. Another thing that is very noticeable is the greater ease with which silver gives lustre than copper. It follows from this that where mixtures of silver and copper are used together the actual quality of lustre produced will depend not so much on the nature of the mixture itself as on the temperature and duration of the firing. It is quite possible, indeed, by under-firing a mixture of silver and copper to produce an effects which would lead anyone to suppose that the lustre had contained silver alone. A great deal has also been said as to certain glazes being much better for lustreing upon than others. There is some truth in this idea, but not very much, for we have found it perfectly possible to produce excellent lustres on glazes of every type; leadless glazes, lead glazes, and glazes with or without oxide of tin. The only type of glaze which seems to be impermeable to the stain of silver and of copper at the lower temperature required for the effect is the felspathic glaze

of hard-paste porcelain, and that I suppose is the reason why the Chinese have never used the lustre process in the decoration of their porcelain.

Having stated as clearly as I can how both the old and the new lustres were made, it now remains to add that of course the value of the lustre process depends entirely on the artistic use of it. The effects of lustre are so beautiful in themselves, and may be made so striking and powerful, that the dangers attendant on its misuse are probably greater than with any other process in the decoration of pottery. Having reduced the scientific and mechanical sides of the process to something like order and method, it is our earnest endeavour to use the beautiful results that have been placed in our hands in such a way as to produce a new English pottery as artistic and beautiful as that of the Middle Ages. To this end we have gradually gathered together what I may describe as a school of young English artists, all of whom have had some training in various art schools of the country under the control of the Board of Education. Every piece of lustre pottery we produce is unique, for either the designs are original conceptions or adaptations of the painters themselves, or in cases where we have been fortunate enough to obtain designs from distinguished decorative artists like Mr. Walter Crane no two pieces are reproduced in the same way. Notwithstanding the perfection to which the chemistry of the process has been brought the method must always remain liable to variations, which also serve to give variety to the pieces. As in old times the best pieces are not made by invention alone, because out of a dozen pieces equally well-painted and fired one perhaps will have a quality surpassing all the rest. Yet I never look on a collection of fine lustre pieces, such as has been exhibited here to-day, without in my mind parodying two lines of Omar Khayyám:—

> "I often wonder what the potter buys
> One half so precious as the things he sells."

DISCUSSION.

The CHAIRMAN said that personally he felt, while listening to the paper, he had been at school again. He had come to the conclusion that, before the paper was read, he understood nothing whatever about lustre pottery, but now he would be able to boast that he understood everything about it. The best of the paper had been the way in which the author had taken the audience into his confidence by telling them the secrets of the manufacture of lustre pottery, in order that they might go and do likewise; but he thought when they had done so, and had produced pottery similar to the magnificent specimens shown, it would be found that Mr. Burton was producing an article greatly in advance of what they were then producing. He entirely agreed with the author that the metallic ware he had shown was not lustre ware; and if it was invented by his (the Chairman's) distinguished great, great grandfather, he was glad he gave it up. The pottery shown by Mr. Burton was entirely different, and had a beauty which had no relation to metallic substances or to the ordinary pottery glaze or enamel. The great beauty of lustre ware was that it had all the advantages of shape and design of ordinary pottery, and in addition, the great added virtue of light. The iridescence of light on the pieces exhibited came as an absolute revelation to him. He had been brought up to admire Florence and De Morgan ware, but they seemed to have become already out-of-date. It was all very well for scientific people to produce such things, but personally he desired to see them produced as a commercial business.

Mr. H. H. CUNYNGHAME, C.B., thought it was impossible to look at the exhibition of pottery collected by the author without feeling that lustre pottery was, to a large extent, the pottery of the future. Almost all the extraordinarily beautiful colours which could be produced by the methods described by Mr. Burton ought to play a very large part in ordinary household pottery, such as jugs, and ornaments of all sorts. Art ought to be progressive; but, in looking at the ordinary crockery, one could not but feel that the manufacturers were merely children at the work, and only at the beginning of art. There seemed to be no reason why, from the simplicity of the process described, ordinary crockery, jugs and basins and so on, in this country, should not be decorated to a large extent. Of course, it was impossible to use works of art for the common things of life; but he really believed that great steps forward in art would be made in this country. He expected he would be in his grave before they occurred, but he hoped his ghost would come back and have the pleasure of looking at the great advance which he was sure would be made in the arts of life, and all the mechanical industries. He was one of those who entirely believed in the future; he was not a pessimist at all, because he believed, in a few years hence, the most extraordinary changes, socially and industrially, would take place. He made the author's acquaintance, some years ago, in connection with the Home Office work; and at that time there was a movement on foot, conducted by benevolent and philanthropic people, who strongly urged that the use of lead in pottery should be absolutely forbidden, because a certain

number of the potters were poisoned. It was thought by those who were advising the Government, that it was possible to use lead without danger; and that it was inexpedient to forbid the use of an important ingredient in the production of the potter's art, unless every attempt had been exhausted to show that the article could be safely used. The pottery trade owed a debt of gratitude to Mr. Burton, not merely for the inventions he had made, but because he was one of the leading men in the industry, who showed by his extreme moderation his willingness to meet every suggestion made by the Home Office. By his breadth of view he prevented rash action being taken in the total abolition of lead. Wiser counsels now prevailed. He was not in the secrets of the arcana of the House of Commons like the Chairman, who knew better than he did the temper of that assembly; but he hoped they would not rashly press changes upon departments which, if carried out, would ruin a national industry. The use of lead was almost essential in certain manufactures, to those who knew how to use it, it being impossible to produce the finest class of work without its use. In the beautiful specimens exhibited by Mr. Burton that evening, a considerable amount of lead glaze had been used, and it would, therefore, be a thousand pities if anybody pressed upon the industry a total prohibition of that material. Of course any department could require that manufacturers who used lead should use it as chemists did, with discrimination, fans and ventilating apparatus being adopted, and care taken that the hands were washed. If people took every precaution in their handling of them, the most dangerous chemicals could be used with perfect safety. It was to a great extent due to the authorities not being aggravated but helped by Mr. Burton that a solution was brought about by which, under certain conditions, lead glazes continued to be used in this country. He desired, in the next place, to make a few remarks in connection with English art. He had been mixed up with educational movements since he first came to London, and remembered the various artistic movements which had taken place, both in London and the provinces, for the last thirty or thirty-five years. Great mistakes in teaching had undoubtedly been made, perhaps the greatest of all being the peculiarly English one of a tendency to go in for fads. In the different schools masters and teachers were to be found who were full of all sorts of curious fancies. The master of one school told him that the theory he adopted was that all boys should evolve art for themselves; they were not taught styles, but were asked such a question as, "How would you, out of the depths of your inner consciousness, decorate a tea cup?" He saw a little boy evolving a style, which the master thought was beautifully original until he (Mr. Cunynghame) pointed out to him that it was the design on the staircase of the building. It was almost impossible to evolve designs out of one's inner consciousness; the greatest designers thought themselves lucky if they produced one good original drawing in a month; and most people had to be content with patching up, or making a slight alteration in, old styles which had come before them. Another fad was to take up a particular art, and for people to say that nothing was good but Etruscan or Celtic. There was good and bad art in every age, but he believed the English nation possessed greater artistic possibilities than any other nation, certainly than the Germans and the modern Italians, though there were still some good artistic people among the mere peasants of Italy. The French seemed to have gone hopelessly wrong, principally on matters of colour. At the present time, they seemed to be losing their national sense of colour. Therefore he thought the art of Europe, in the future depended, to a great extent, on this country. He was certain that lustre pottery would be enormously developed, and that it would meet with large sales. He hoped high prices would be obtained, and that the development of the art would prove to be one of the future sources of national prosperity. England would have to give up making cheap matches, and cheap twopenny things of a small character; the Japanese and Chinese would soon take all that work off their hands; but the thing they would not be able to take out of the hands of the people of this country was modern English art, such an excellent representation of which had been exhibited by the author.

The CHAIRMAN believed that most of the articles exhibited contained heavy lead glaze, but he desired to point out that Messrs. Pilkington, of Clifton Junction, were one of the few firms who had so far escaped without a case of lead poisoning of any description. In spite of using heavily leaded glazes, by looking after the cleanliness of their shops and workmen, and paying attention to ventilation, they had avoided the occurrence of any such evil.

Mr. PHENÉ SPIERS referred to his acquaintance with Mr. De Morgan, and that gentleman's first attempts to produce lustre pottery. Mr. De Morgan had two entirely different moods. He was the son of Professor De Morgan, the great mathematician, from whom he inherited a strong scientific tendency, and he was also a very great artist. Those two moods were always agitating him first in the one way and then in the other. At one time he would be more pleased with the variety of colours, which the accidents of the furnace had produced, while at other times when in his scientific mood he preferred the more perfect firing. He thought Mr. Burton was working on the right lines in endeavouring to evolve a style of his own. In all the pieces exhibited the author had tried to work out new designs and not to imitate the works of earlier potters. He thought the members were under a deep debt of

gratitude to Mr. Burton for the great pains he had taken in writing the paper, and the information he had placed at their disposal.

Mr. WALTER F. REID enquired what chemical combination took place when the particular stage of the firing was reached to which the author had called attention. Among many interesting samples which Mr. Burton had specially prepared for exhibition, one apparently did not show the copper at all, but at the other end of the series one piece was over-fired. Could Mr. Burton state in what form the copper existed there? Mr. Cunynghame had shewn in the lectures he had given at the Society that very beautiful enamels could be made by the silicates of the metals. Were the coloured surfaces shown by Mr. Burton silicates upon which a very small quantity of the metal had been reduced on the surface, or in what form did it exist? It was not a true enamel, but one with a certain undefinable play of colours upon it, which was not the same as when, for instance, metals were enamelled with a true silicate. The author used the expression more than once that the colouring matter stained the glaze over the rest of the body of the ware. Was not that to a certain extent a volatilisation of the material? He was thinking for the moment of the iridescence that was produced on glass by the volatilisation of chlorides in the furnaces. There it was clearly the volatilisation of the ingredients, and a beautiful iridescence was produced on glass in that way. Perhaps the author could give some information with regard to the particular nature of the glaze which was produced on the surface of enamel, if he might so call it. He did not think that the vermilion, or cinnabar, used by the old potters in their composition, was entirely useless. It would puzzle modern chemists to find a better diluent which would volatilise at the same temperature as sulphide of mercury. There was a risk in olden times, when potters had not the same technical means as modern potters possessed, unless a diluent were used. Such things were used at the present day. For instance, at the present time if a gardener wished to sow grass seed he mixed it with sand and earth; and therefore the old potters when they were pottering about probably found by actual experiment that cinnabar was a material which would volatilise in the heat of the furnace, and they simply used it to dilute their lustre or enamel.

Mr. BURTON, in reply, said there were many chemical theories as to what caused the stain. The old people thought it was a silicate of the oxide or sub-oxide; but he was not at all sure it was a silicate. His own impression was that it was probably a metal, *i.e.*, either pure metallic silver or pure metallic copper, which went in as such, was held in suspension, and stained the glaze. It had been imagined that the beautiful ruby stain of copper was due to some oxide of copper, but that was all theory. Dr. Mellor had been experimenting on this subject to find out whether it was due to sub-oxide or metallic copper, but he did not know whether a satisfactory conclusion had been arrived at. Personally he thought the metal was volatilised at a much lower temperature than they had been in the habit of supposing, and, under those circumstances, it stained into the glaze, producing, in the case of silver, a yellow film, and, in the case of copper, a red film. What could be done in that way by the volatilisation of the staining material, whatever it might be, was well exemplified in some pieces he had exhibited. Mr. Reid's remarks that cinabrio was an exceedingly good diluent because it volatilised at a low temperature might be true, but in his (Mr. Burton's) opinion its use was unnecessary; it was employed for the reasons he gave in his paper. The clay was the diluent, and the old potters used precisely the same proportion of clay in the mixtures to which they added cinabrio as those to which they did not. He had made experiments which proved that the cinabrio volatilised and disappeared; it had no effect whatever upon the pottery.

Mr. C. H. BRENNAN inquired whether the lustre pottery was made with a china or terra cotta body.

Mr. BURTON replied that it was perfectly immaterial which was used. He had not seen a piece of lustre pottery made on hard-paste porcelain, because it was impervious to the metallic stains at the low temperature at which the things were made. China clay was merely a convenient diluent to add to the metallic compound for the purpose of getting something with which to paint. Red-brick clay, whitening, ground-up sand or ground-up coal ashes could be used.

Mr. E. C. CORBIN (Messrs. Goode and Co.) asked what was the best glaze to use.

Mr. BURTON said that Mr. Cunynghame, who had had a good deal of experience with glazes, had rightly said that most of the glazes he (the speaker) used were heavily leaded. Those glazes had a surface and a texture which no other glaze in the world possessed. There was a tremendous difference between a leaded glaze and a leadless glaze, whether it was a hard-paste porcelain glaze, or the leadless glaze which had been made in response to a rather clamorous public. Beautiful results could be obtained with both, but the one was not equal to the other. The old Persian lustre was made on leadless glaze, and some of his (the speaker's) pieces were on leadless glazes, but the Hispano-Moresque and the Italian majolica were made with glazes more heavily leaded than any used in England to-day. The only glaze that which seemed to be antipathetic

to the lustre process was that of hard-paste porcelain, which consisted of little more than fused felspar.

Mr. VAN DE PUT inquired whether it was not the fact that the Arabians and the Moors were unable to obtain a red pigment.

The CHAIRMAN, in proposing a hearty vote of thanks to Mr. Burton for his extraordinarily interesting paper, said he did not know whether all the papers at the Society of Arts were of an equally interesting character; if they were he was afraid he would be a very bad attender at Parliament in future. He first knew Mr. Burton when that gentleman was a chemist, and he (the Chairman) was in short coats; then Mr. Burton became a man of business and started a new factory; then he became an artist, and subsequently a public-spirited man who looked after the interests of the pottery industry as a whole; and, last of all, he found he had written the only readable books giving a history of the production of earthenware and porcelain—books not merely to be taken up and read by the individual who was a specialist in china, but of real interest to anyone who took an interest in art; and the paper he had just delivered fully came up to his great reputation. Mr. Burton had taken a great deal of interest in the pottery societies of North Staffordshire, which looked after the question of lead poisoning; he was always travelling about the Continent, finding out the methods of competitors abroad, and bringing back all that was best for reproduction at Clifton Junction. At the same time he was always willing to give the benefit of his inventions and his views to his brother potters; and the work he, his brother, and Bernard Moore had done between them in developing the artistic as opposed to the commercial side of English pottery could not be overrated. He only hoped that, having developed the artistic side to such an extent as he had done, he would further develop the commercial side of the beautiful invention he had described.

The resolution of thanks was then put, and carried unanimously.

Mr. BURTON, in reply, said it had been a very great delight to him that Mr. Wedgwood had taken the chair, because his first knowledge of pottery came from his labours as a chemist to the Chairman's relatives. He considered Wedgwood the greatest potter of England, and it was a very great honour and pleasure to him that anybody of the name of Wedgwood had taken the chair. He desired to thank Mr. Cunynghame for his presence and his very frank and outspoken views, especially with regard to English art. He had known Mr. Cunynghame as a public official for a great many years, and knew that the English pottery trade owed him a debt of gratitude for helping them to settle their difficulties with the Home Office in the sensible and practical way they were able to do some years ago. He also knew that Mr. Cunynghame had been an earnest student of art in this country, and that he was absolutely correct when he said that English people were apt to suffer from aberration of taste, and form a fantastic notion of art. The English nation was suffering from a profound belief that everybody but English people could make artistic things. In his opinion England was at the present time producing finer artistic work in almost every branch of decorative art than any other nation, but the English people who ought to be buying it were allowing the best pieces to be exported. On the other hand, English people went on to the Continent, came back with some wretched trumpery which was not worth buying, and said, "See how artistic the Frenchman or Italian is!" In conclusion, he desired to express his indebtedness to the many friends who had lent him specimens for the purposes of exhibition, and to the authorities at the South Kensington Museum for a similar courtesy.

The following is a list of the examples of pottery lent for exhibition:—

Victoria and Albert Museum (lent by the Board of Education):

Glazed earthenware dish, majolica lustred. Italian, fourteenth to fifteenth century.

Enamelled earthenware plateau, Hispano-Moresque in gold lustre, fifteenth or sixteenth century.

Enamelled earthenware plateau, Hispano-Moresque with shield of arms and arabesque in front. fifteenth century (Valencia).

Water bottle, blue glazed earthenware in metallic lustre, Persian, fifteenth or sixteenth century.

Dish of lustred earthenware, by William De Morgan, English, nineteenth century.

Cream coloured enamelled earthenware dish, lustred and painted in blue, with eagle in relief in centre, bearing a shield of arms, Spanish, nineteenth century.

Cream coloured enamelled earthenwere vase, lustred and painted in blue with arabesque ornament, nineteenth century, Spanish.

Bowl, glazed and lustred earthenware, Clement Massier, French, nineteenth century.

Vase, iridescent green glaze, Zsolnay, Hungarian, late nineteenth century.

Messrs. Thomas Goode and Co., 17, South Audley-street, W.—A collection of very fine specimens of old English lustre.

Bernard Moore, Esq., Stoke-on-Trent.—A collection of modern examples of his lustre ware.

Messrs. Liberty and Co., Regent-street, W.—A collection of lustres by Zsolnay and Co.

A. Wenger, Esq., Etruria, Stoke-on-Trent.—A collection of modern Spanish, Italian and French lustre pieces.

Messrs. Morris and Co., Oxford-street, W.—Examples of De Morgan and Cantegalli lustres.

Messrs. Maw and Co., Jackfield, Salop.—A collection of lustre vases and tiles.

Messrs. Craven Dunnill and Co., Jackfield, Salop.—A collection of lustre vases and tiles.

Messrs. Carter and Co., Poole, Dorset.—A collection of lustre vases and tiles.

William Burton, Esq.—A collection of pieces by Clement Massier, Jerome Massier, Cantegalli, De Morgan, Maw, and other makers.

Lewis F. Day, Esq.—A collection of lustre pieces, by Clement Massier and Zsolnay.

Pilkington's Tile and Pottery Company, Limited, Clifton Junction, near Manchester.—A collection of their new Lancastrian lustres.

Mr. WALTER C. HANCOCK writes:—It would be interesting to know whether any analyses have been made of the surface layers of specimens of old lustre pottery, and if so, what light they throw upon the materials used in its production, assuming that the metallic component to which the lustre is due is present in sufficient quantity to be definitely estimated. As the "lustreing" temperature is 650° C, and the melting point of copper is about 1100° C, which is of course far below the melting points of other metals used to produce lustre, such as silver or gold, it appears probable that to some extent definite chemical combination occurs between the metal and the glaze, since the latter is penetrated by the former. On this point the microscopical examination of a transverse section of a specimen of lustre ware would possibly give a good deal of information. From Mr. Burton's experience it seems to be clear that the lustre effect is produced by two factors, a temperature of 650° and a simple reducing atmosphere of carbon monoxide, for example, and that the products of destructive distillation of carbonaceous material, which would occur when broom or brushwood was used for firing the kiln, are not necessary for obtaining the result. Mr. De Morgan has pointed out that the combustible, however, must be free from sulphur. It seems somewhat curious that from the writings of Piccolpasso a red or ferruginous clay was used in the pigment, whereas Mr. Burton and others have employed simply a white clay. It would have appeared probable that the amount of ferric oxide present in a red ochre or ferruginous clay would have produced a marked effect upon the character of the lustre. A possible explanation of the absence of any apparent effect may be, that the ferric oxide is reduced by the surrounding atmosphere of reducing gases to the ferrous condition, and in that condition unites with the silica of the glaze.

ARTS AND CRAFTS.

Home Arts and Industries at the Albert Hall and Earl's Court.—Attention has been called during the last few weeks, both at the Albert Hall and at Earl's Court, to what are called "home arts and industries," and it is interesting to consider the relation of such crafts or industries practised in widely different lands, both to each other and to production in general. It is easy enough to laugh at efforts made to promote home industries, and to say that the days of anything but manufacture on a large scale are numbered. It is also, unfortunately, easy to find fault with some of the methods employed by enthusiastic would-be helpers of such industries, and to point to sufficiently serious defects in some of the work turned out by the less satisfactory of the "home art" classes. For all that, home arts in their larger sense have come to stay. If we look around us we see not only that our English Home Arts and Industries Association has perseveringly exhibited its products for a goodly number of years, but that work of much the same kind is being done all over Europe. Of course, things are differently managed in different countries. While in a country which, like our own, is highly developed industrially, it is very largely a question of teaching the cottager new crafts or reviving old, all but forgotten, trades—the effort in more backward lands is merely directed towards keeping industries already well established from being driven from the field by the competition of factory and machine labour, or to finding a larger market for peasant work. The strong feeling in favour of the preservation of race characteristics, the increased interest taken in ethnography, and the tendency in certain quarters to cry out for decentralisation, have all had their share in the fostering of these home arts—and the prevalence of international exhibitions has enabled us to see how universal the movement is, and has tended to increase its impetus. At Milan last year, peasant crafts from various countries were well represented, and at present at Earl's Court we have a very good opportunity of seeing what is being done in this kind of work in that part of the Balkan Peninsula which has been comparatively recently freed from the dominion of the Turk. The most important exhibit of this kind of work is probably that in the Servian section of the Pirot Carpet *Zadruga*—a kind of co-operative association. The workers, who are women, carry on their trade in private houses, and the society is aided by Government capital. Bulgarian carpet weaving is represented by a working exhibit of the Royal School of Carpet Weaving. It is evidently not only in the British Isles that doctors disagree as to the relative merits of working with or without a pattern, for while the Servian weavers use no sketches or drawings whatever, the Bulgarians all have their designs carefully attached to their looms in a prominent position.

Both from Servia and from Montenegro come exhibits of peasant embroidery and hand-loom weav-

ing. The embroidery is mainly, of course, in tent stitch and cross stitch, curiously un-Western and yet not quite Eastern in character. It is really more nearly allied to Hungarian and Transylvanian work than to anything else—though it has some affinity with that which comes from the islands of the Ægean. The Montenegrin work exhibited is executed mainly by the students of the technical school of Cetinje, which is under the patronage, nominally at least, of Princess Yolanda (granddaughter of Prince Nikola, of Montenegro).

It is, of course, from one point of view, very satisfactory to see that home industries all over the world are being supported and encouraged—that they are even (as we saw at the South African Exhibition) being introduced into fresh countries. It constitutes a by no means unnecessary protest against the triumphal progress of the machine, and it points to an interest in a simple form of artistic craftsmanship which has too often been neglected or despised. Nevertheless, the very extent of the movement ought to give us pause here in England. We are talking a good deal just now of the beauty of hand work, of the joy of individual production—we are encouraging art students, who have their living to make, to dabble in crafts, urging unoccupied women to turn their attention more or less seriously to what is often called "art work," and inducing the peasants in our rural districts to take up lace-making, wood-carving, or what not, in their unoccupied time. So far as all this is looked upon as healthy recreation of a more or less educational kind there is nothing to be said against it and much to be counted in its favour. Can we be sure that from the economic point of view the movement is equally to be commended? Is the ordinary British buyer of home art handicraft productions open-handed enough to support this movement? Will his patriotism take him (or her) to the length of paying five or six shillings for say the trimming for a blouse embroidered in England where money is plentiful and the standard of living is high, when he can get something "very nearly as good" imported from Macedonia, or Servia, or Hungary or somewhere else where money is scarce and the cost of living is low, for three shillings or half a crown? We may hope so without any very strong conviction that it will. And if not, is there not, or will there not be at no very distant time, at least a possibility of something not so very unlike sweating in these crafts which we are encouraging so vigorously? Is it quite safe to insist upon the claims of hand-work to beauty and originality without insisting no whit less persistently upon its claim to be paid for? There seems to be a likelihood that if we fail to educate public opinion in this matter we may be doing more harm than good in trying to revive hand production on anything like a large scale.

Artists at Work.—We have reached the time of year when, with the beginning of summer, the more commercial side of Arts and Crafts falls into the background and such more or less amateur exhibitions as the show of the Home Arts and Industries Association and the Society of Artists at Work come to the front. After all the season spells something not unlike frivolity—and, though the various collections on view at this time of year are not by any means uniformly frivolous, we feel that it is fancy-work, lacemaking and other crafts, connected rather with personal adornment or the furnishing of a summer bungalow than with the permanent decoration of the home, that are now claiming attention, and getting it.

The Society of Artists at Work held their May exhibition at Knightsbridge this year instead of at the Grafton Gallery. Naturally many of the exhibitors were the same as on former occasions, and there was a certain sameness about a good number of the exhibits. The novelty of seeing people actually working at their trades in an exhibition building palls after a time. It is not possible to introduce new crafts every six months in order to stimulate the interest of the frequenter of exhibitions. Still, the scope of the show has been somewhat widened this spring, and several methods of ornamenting fabrics, &c., were to be seen for the first time.

Lace, Textile Decoration, and Jewellery.—Lace and embroidery were amongst the most amply represented arts. Irish, Buckinghamshire, and Devonshire laces were shown in fairly large quantities, but the most interesting exhibit in this section consisted of reproductions of the famous quilt of Henri II. in *filet brodé*. The original of the quilt is now at Paris, in the Cluny Museum, and is one of the greatest treasures of that storehouse of old embroidery. (It is rather difficult, by the way, to make up one's mind whether this work should be classed as lace or embroidery—it really comes under either head.) It was interesting to see finished reproductions of the squares of which the coverlet is composed and also the small frames with the work in different stages of progress, with the threads of the "filet" firmly attached to their sides while the work of putting in the pattern was started.

The other fairly new departures in textile work are very different in character. Poker work on velvet, though it may lend itself to making peacock feather designs on a greeny blue ground, is not a very serious form of art. Painting on linen in washable paint looks rather attractive, but it is difficult to banish from one's mind the feeling that patterns so executed must inevitably wash out. Stencilled sunshades afford an opportunity of producing really very pretty effects of colour.

There is a good deal of embroidery on linen and it is pleasing to note that several exhibitors seem to have adopted a definite style to which they practically confine themselves. One show was composed almost entirely of work of a pseudo-Epyptian character, another of characteristically Oriental embroidery, a third of reproductions and adaptations of Jacobean

crewel-work, and yet another of appliqué of linen on linen in a style reminiscent of the works of Miss Anne Macbeth.

The bulk of the silver work was made up of buckles, chains, brooches and other jewellery, but there was one large cross of silver and blue-johnstone which was both pretty and interesting. An exhibit consisting mainly of hornwork in various colours proves that we are learning over here to work in a material which used to be considered to belong almost exclusively to the French. Of course, this is not the first time by any means that English hornwork of this kind has been shown, but the exhibits are now on a larger scale than heretofore.

OBITUARY.

SIR DIETRICH BRANDIS, K.C.I.E., F.R.S.—Sir Dietrich Brandis died at Bonn on the 28th ult., after six months illness. Sir Dietrich was elected an Honorary Corresponding Member of the Society in 1896. His first connection with the Society was as far back as 1872, when he took part in the discussion on Mr. James Collins's paper on "The Study of Economic Botany." Of late years after his return from India he took an active interest in the Society's work. He presided at Mr. Herbert Stone's paper on "The Identification of Wood," in 1901, and spoke in several of the discussions on Forestry.

He was a son of Dr. S. A. Brandis, Professor of Philosophy at Bonn University, and was born in 1824. In 1856 he was appointed Superintendent of the Forests in Pegu, and in 1864 he was made Inspector-General of Forests to the Indian Government. This office he held until 1883, when he retired from the service. In 1887 he became Director of the Practical Course of Forestry on the Continent, in connection with Cooper's Hill, and this appointment he held until 1896. He was made a C.I.E. in 1878, and received the K.C.I.E., in 1887. In 1875, he was elected a Fellow of the Royal Society.

GENERAL NOTES.

PHOTOGRAPHIC DARK ROOMS.—The *Photographic Monthly* for June contains in addition to its usual contents a list of dark rooms in England and abroad where the travelling photographer may change his plates or develop his plates and films. The list of English rooms is a long one, but the Continental list might be largely extended, as numerous tourist resorts where such facilities exist are not mentioned. But, though far from complete, the list will doubtless be useful to amateur photographers who like to develop as they go along. Experience, however, with regard to Continental dark rooms shows that in the tourist season their proprietors are often too busy to allow the use of their rooms to outsiders though they are ready enough to advertise that they do so. There is more profit to be made by developing Kodak films than by lending rooms for their development.

LETCHWORTH HOUSING EXHIBITION.—The preparations at Garden City, on the site of the Urban Housing and Rural Homesteads Exhibition, which is to be opened in July by the Marquis of Salisbury, are reported to be far advanced. Three sites of ground have been set apart at Letchworth for the Exhibition; two for the creation of rural homesteads and small holdings buildings, and one near Letchworth Station for urban cottages, ranging in cost from £175 to £250. There will probably be some fifty houses erected of at least thirty different types, and these should form a great attraction to visitors from London and elsewhere who are interested in questions of housing reform and model cottages. The Exhibition is much more comprehensive in its scope than was the 1905 Cheap Cottages Exhibition, and, besides comprising cottages of a higher value and wider range than before, an exhibition of manufacturing implements, dairy implements and appliances, builders' merchants' materials, temporary buildings, fowlhouses, beehives, food stuffs, &c., will be held. Some of the principal furnishing firms of London have also undertaken to completely furnish numbers of the cottages, and an important Photographic Exhibition will be held during the three months that the Exhibition is open. Mr. R. Winfrey, M.P., is responsible for a set of small holding outbuildings, which are being erected by the South Lincolnshire Small Holdings' Association. The Concrete Machinery Company will be represented by a house, utilising local sand and cement, the blocks being manufactured on the site.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JUNE 10...Geographical, University of London, Burlington-gardens, W., 8½ p.m. Dr. Otto Pettersson, "Oceanic Circulation."

TUESDAY, JUNE 11...Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m.
Colonial, Whitehall Rooms, Whitehall-place, S.W., 8 p.m. The Hon. Thomas Bent, "Victoria and its Resources."
Horticultural, Vincent-square, Westminster, S.W., 3 p.m. Mr. W. P. Wright, "Arches, Pillars, and Pergolas."

WEDNESDAY, JUNE 12...Biblical Archæology, 37, Great Russell-street, W.C., 4½ p.m.

THURSDAY, JUNE 13...Royal, Burlington-house, W., 4½ p.m.
Antiquaries, Burlington-house, W., 8½ p.m.
Mathematical, 22, Albemarle-street, W., 5½ p.m.

FRIDAY, JUNE 14...Astronomical, Burlington-house, W., 5 p.m.
Physical, Royal College of Science, South Kensington, S.W., 5 p.m.

Journal of the Society of Arts.

No. 2,847. VOL. LV.

FRIDAY, JUNE 14, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

ANNUAL GENERAL MEETING.

The Council hereby give notice that the One Hundred and Fifty-third Annual General Meeting for the purpose of receiving the Council's Report and Treasurers' Statement of receipts, payments, and expenditure during the past year, and also for the election of officers and new members, will be held in accordance with the By-laws on Wednesday, 26th June, at 4 p.m.

(By Order of the Council),
HENRY TRUEMAN WOOD,
Secretary.

H.M. THE KING OF DENMARK.

The Council of the Society having elected H.M. the King of Denmark an Honorary Royal Member, H.R.H. the Prince of Wales, as President of the Society, graciously communicated to King Frederik the fact of his election, and has now received from His Majesty the following letter of acceptance:—

Buckingham Palace,
June 11th, 1907.

SIR,—I have great pleasure in accepting Your Royal Highness's kind invitation to become an Honorary Member of the Society of Arts, of which You, as its President, have given me such an interesting description in Your esteemed letter of the 4th instant.

I am very glad to meet the wishes of your Royal Highness and those of the Members of the Society of Arts, in associating myself with this old and useful Institution, and have the honour to remain, Sir,

Your Royal Highness's
Most faithful friend,
(Signed) FREDERIK,
King of Denmark.

His Royal Highness
The Prince of Wales.

CONVERSAZIONE.

The Society's Conversazione will be held, by arrangement with the Council of the Royal Botanic Society, in the gardens of that Society, Inner Circle, Regent's-park, on Tuesday evening, July 9th, from 9 to 12 p.m.

The central portion of the gardens only will be used. The Conservatory and the Club house will be open.

The reception, by Sir Steuart Colvin Bayley, K.C.S.I., C.I.E., Chairman, and the other members of the Council, will be held at the entrance to the Conservatory, near the Broad-walk, from 9 to 10 p.m.

Each member is entitled to a card for himself (which will not be transferable) and a card for a lady. In addition to this, a limited number of tickets will be sold to members of the Society, or to persons introduced by a member, at the price of 5s. each, if purchased before the day of the conversazione. On that date the price will be raised to 7s. 6d.

Members can purchase these additional tickets by personal application, or by letter addressed to the Secretary at the offices of the Society, John-street, Adelphi, W.C. In all cases of application by letter a remittance must be enclosed. Each ticket will admit one person, either lady or gentleman, and must be signed by the member applying for it.

Tickets will only be supplied to non-members of the Society on presentation of a letter of introduction from a member.

A programme of the arrangements for the evening will be published in due course.

COVERS FOR JOURNAL.

For the convenience of members wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1s. 6d. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

Thursday, May 30, 4.30 p.m.; CHARLES EDWARD HOBHOUSE, M.P., Under Secretary of State for India, in the chair.

The CHAIRMAN, in introducing the reader of the paper, said the subject to be discussed was one of great interest, not only to those who were immediately connected with India, but to all who had watched the experiments conducted in that country, which they thought might be repeated on a useful, it not so large a scale, in other parts of the world.

The paper read was—

IRRIGATION COLONIES IN INDIA.

By LAURENCE ROBERTSON, I.C.S.

GENERAL DESCRIPTION.

The subject on which I have been invited to address you this afternoon is that of the Irrigation Colonies in India, with reference more especially to the three great colonies that have been established in recent times—the Chenab colony and the Jhelum colony in the Punjab, and the Jamrao colony in Sind. The area commanded by the three canals that give their names to these settlements, and upon which they depend for their existence, amounts in the aggregate to over 8,800 square miles, an area which is comparable with the extent of one-third of Scotland. Of the total, the Chenab colony, with 5,300 square miles, is by far the largest; the Jhelum colony comes next with 2,000 square miles, while the Jamrao lands cover 1,500 square miles.

The colonisation of such vast territories, practically uninhabited, almost the whole of which was at the unfettered disposal of the State, which were known to contain land of the highest fertility, and where successful agriculture can only be practised by the aid of irrigation, is a subject which lends itself to treatment from many different points of view. There is, first of all, the engineering problem of bringing the water from the rivers over the area commanded in its many aspects. The river, from which the canal is to derive its supply, must be harnessed by a dam, which, while allowing the surplus waters of the summer floods to pass down the channel, will enable the engineer to hold up, and divert into his canal the scanty but precious supplies of the winter season, when the water is at its lowest. The alignment and construction of the main canal and its many branches, down to the village watercourse, so as to make the fullest use of the water available in the most economical way, present problems of great difficulty.

Happily I am relieved from entering into any discussion of these matters, for I find that in April, 1902, Mr. Sidney Preston read before this Society a paper entitled "Recent Developments in Punjab Irrigation," in which he fully explained the grand work which the State engineers in India have been able to accomplish, in making the waters of the great rivers of the Punjab and Sind available for the fertilisation of the vast plains, arid and uninhabited some fifteen years ago, which now present a picture of contentment and affluence.

Starting then with the fact that the engineering problem has been solved, and that the vast uncultivated plains can be rendered fertile by irrigation, the special aspect of the colonies to which I propose to devote myself this afternoon concerns the methods adopted for peopling these tracts and for securing the prosperity of the colonists. It was evident that this work could not be entrusted to the ordinary staff of the districts in which the tracts traversed by the irrigation systems lay, and for each of the three colonies which I have mentioned the Government appointed a selected member of its service as Colonisation Officer, and entrusted him with the whole arrangements for attracting settlers, allotting them land, and nursing the growing settlements to success. This appointment was made for the Chenab colony in 1892, for the Jamrao colony in 1898, and for the Jhelum colony in 1901, and colony work in the three areas may be said to have commenced from these dates.

THE SQUARE SURVEY.

Before actual steps could be taken to bring the settlers, it was necessary for the Colonisation Officer to survey his vast estate and to lay it out in villages and holdings of convenient size. The system adopted was to demarcate over the whole area a series of squares, which are either of 27, 25, or 16 acres in extent, so that the map at first prepared resembles a chess board. This square forms for all three colonies the unit of revenue management for colonisation purposes. It is the unit of allotment for all classes of settlers,

and the system of irrigation channels is so arranged that each square has a separate inlet for water from a water-course. In the following remarks a square always refers to this unit. I do not wish to detain you by entering into the details of this survey system or to give a long account of the difficulties encountered and the hardships endured by the Colonisation Officer and his Indian surveyors in carrying it out. But when it is remembered that the survey parties often worked across vast stretches of uninhabited country, where the only source of water supply might be a brackish well 100 feet deep, and that in order to complete the work it was often necessary to remain in the field throughout the hot season when the temperature rises to over 110° Fahr. in the scanty shade of the scrub jungle with which parts of the country was covered, it will be realised that powers of organisation, energy and determination were required from the officer in charge and great devotion to duty from the Indian surveyors under him.

It will be convenient here to anticipate for a moment the arrival of the settlers. I have spoken of the square as the unit of allotment, but each square is too large for the purposes of irrigation if water is to be used economically and if crop registration, upon which depends the amount of land-and-water-tax each cultivator will have to pay, is to be efficiently performed. Along the sides of each square, therefore, points were demarcated, and by carrying small ridges across the square it is divided up into small fields, each of approximately one acre in extent. The convenience of this measure was not at first realised in the Chenab Canal, and considerable tracts had already been colonised before it was devised, but experience soon showed that, unless some uniform system of sub-division was enforced, water would be wasted and the cultivators would be helpless to protect themselves from being fleeced by the staff which measures up the cultivation and assesses the taxes to be levied at each harvest. Sub-division is now rigidly insisted on from the beginning and the measure is of immense practical importance in effecting economy in the use of water and in protecting the cultivators from illicit demands, while at the same time immensely increasing the efficiency of the inspecting officers, who can see at a glance whether the amount of cultivation has been correctly registered. This system was not evolved and finally brought into operation without an immense amount of trouble and scrutiny of details. For on the one hand the incoming colonists were often disinclined to spend time and labour upon work that seemed unnecessary to them at first, but they soon grasped the convenience of the system, and the work was done; on the other hand, the system of squares, however carefully laid out, was constantly diverging from the true, and re-measurement and re-calculation of areas had often to be done before the exact size of these internal fields was ascertained, and an accurate map produced.

After the whole area to be colonised in any particular tract had been subjected to a square survey, it was necessary to divide it up into villages of convenient size, the average gross area being between 1,500 and 2,000 acres. This work was done by the Irrigation Department, the main principle followed being that the lands in each village should be irrigable from its own water-course to the exclusion of all other lands, and that each such water-course should take off from a Government channel. The boundaries of the villages, where they were not canals, distributaries, roads, drainage channels, or the like natural features, were coterminous with the lines or diagonals of the squares.

When the Colonisation Officer had received his village maps he marked off a plot for the village site, an area of about 20 per cent. of the village lands for grazing and communal purposes, and the remainder he held available for allotment to the incoming settlers. The map below, shows at a glance how the waste lands were divided up into squares and villages laid out. (Fig. 1.)

Terms of Allotments.

The Chenab.—While all this work was going on, the important questions of the classes of settlers to be invited to take up land and the terms of the grants were under discussion and settlement. In the Chenab colony the object in view was two-fold, first to relieve, as far as might be, the pressure on the land in some of the densely populated districts of the Punjab, and, secondly, to colonise the area available with the best types of Punjab farmer who would cultivate their own holdings as far as possible without the aid of tenants, and ultimately constitute healthy agricultural communities. It was decided to divide all grantees into three classes—peasants, yeomen, and capitalists. Each peasant was, as a rule, offered one square in the Punjab, or about 27

acres, each yeoman four or five squares, or 104 to 130 acres, according to his capacity, and each capitalist a larger area up to 500 acres. All grants are on a provisional footing for three years, during which the grantee must prove his capacity and determination to succeed by bringing his allotment under cultivation. At the expiry of that period, if the grantee has complied with the terms of the grant as to clearance and residence, a peasant is given a permanent right of occupancy in his holding, which is hereditary but inalienable by gift, sale, will, or mortgage, and a yeoman was at first given complete proprietary rights, but is now given the restricted tenure of the peasant, while the capitalist receives full proprietary rights. No fee is charged to the peasant in return for the grant of occupancy rights; the yeoman generally pays a small premium of Rs. 4 or Rs. 5 an acre, while the capitalist is required to purchase his proprietary rights for a payment per acre which varies directly

with the number of squares in his grant. In all cases the grantees have to pay for the expenditure incurred by Government on the survey and on the construction of the village water-courses. Two harvests are allowed free of all State demands for revenue or water-rate to all new settlers, and liberal terms of payment are arranged for all initial demands, the peasants more especially being assisted by State advances repayable on easy conditions. Peasants are required to reside in the village in which their holdings are, and yeomen on or close to their grants, while capitalists may either take up their residence on their grants, or appoint approved resident agents. There are also other special classes, who were given allotments on special terms; as, for instance, Mahzabi Sikhs—a class which supplies the best recruits for the pioneer regiments of the Indian Army—and camel-grantees, who consisted mostly of the original nomad graziers of the tract. The latter were given allotments on condition of maintaining for each square allotted a camel suitable for army transport work.

The Jhelum.—The Jhelum colony was at first intended to be colonised on exactly the same lines, but before work had begun it was decided, on the recommendation of the Horse-breeding Commission, to start a huge experiment with the object of ensuring a steady supply of horses for the Indian Army. A great portion of the area available was reserved for settlers, who, in addition to complying with the terms imposed upon the grantees in the Chenab colony, would undertake to maintain, in proportion to the area of each grant, a number of mares passed as fit for breeding army remounts. The selection of colonists had, therefore, to be carried out not so much with reference to agricultural capacity as with reference to natural aptitude for horse-breeding. This change will no doubt lower the agricultural efficiency of this colony in comparison with the Chenab, but the horse-breeding industry appears now to show good prospects of success.

The whole of the horse-breeding work has been placed under the supervision of the Army Remount Department, its officers acting as assistants to the Colonisation Officer. The settlers' mares are served free of all charge by Government stallions located in the colony, and Government has a lien on all produce up to one year of age on the payment of a fair price.

The Jamrao.—For the Jamrao colony it was determined to rely mainly on the Punjab for settlers. Sind itself is already for the most part under-populated, and the distribution of the available land among the inhabitants of the province would have meant the depopulation of the tracts from which the settlers came. The claims of the indigenous agriculturists were, however, by no means neglected, and it was only after their requirements had been fairly and considerately met, that the remainder of the area available was reserved for foreigners from other parts of India. The agricultural methods of Sind, more especially of the parts neighbouring on the Jamrao lands, were inefficient, and it was hoped that the importation of superior agriculturists would lead to the introduction of superior methods among the indigenous farmers, a hope which has to a great extent been justified. The conditions of the grants were modelled upon the Chenab terms, and the same classes of grantees were invited to take up the land.

One class of grantees on this canal may be given a few words of special notice. When Sind came under British rule all the younger branches of the Talpurs, the then reigning family, were pensioned off either with grants of land rent free or with cash stipends. In most cases these pensions were to be discontinued or reduced after a period of years or on the death of the original grantee, in the hope that the descendants would in time find means of earning their own livelihood without State assistance. As time went the families grew, while the source of income steadily diminished. The descendants showed little power of recognising their altered position, and, notwithstanding the efforts of the authorities to encourage habits of industry and thrift by education and other means, there were large numbers of young Talpurs who would not work or who could find no congenial employment and who were reduced to the very verge of destitution. The thing threatened to become a social evil of some magnitude. The opportunity was, therefore, taken to reserve a portion of the Jamrao lands for selected young men of the Talpur families. To make matters easier the conditions were somewhat relaxed in their favour; they were given free grants of money to start them, and it is gratifying to find that the policy has met with some success. But they are not popular with the Colonisation Officer, who wants to see his lands used to the best advantage, while the Talpurs are for the most part absentee landlords, taking very little interest in their estates.

Grants to Government Servants.

In addition to the classes of colonists which I have mentioned, considerable areas were reserved on all these canals for native Government servants of all departments, the class of grant given being arranged according to the status of each individual; thus a private soldier would ordinarily rank as a peasant, a native officer as a yeoman, and an official of higher grade as a capitalist. Specially meritorious service may be rewarded by the remission of the initial payments due.

Colonisation Methods.

I have now briefly described the arrangements made for the reception of the colonists in their new homes, the classes of settlers required, and the conditions upon which the land was offered for occupation. The working out of the scheme devolved upon the Colonisation Officer.

The land was there, and the water that was to fructify it. But before the one could be successfully applied to the other there was an immense amount of manual labour for the incoming colonist to perform. He was relieved of all work in connection with bringing the water to his holding. That had all been done before his arrival. But the land had to be levelled or cleared, the field ridges thrown up to divide his holding into one acre plots, and many other tasks performed, before actual cultivation could begin. Besides he had to construct some sort of shelter for himself and his family—not, of course, a permanent abode; the construction of that came later, but a rude temporary hut which would serve until a harvest or two had put money in his pocket and had assured him that his new home would be permanent. An isolated Indian peasant would have found it impossible to do all this single-handed. It was, therefore, determined to base operations as regards peasants at any rate on the caste organisation of India, in other words, the colonists in each village were all of the same caste or tribe drawn from the same neighbourhood at home, and villages allotted to the same caste or tribe were grouped together in large blocks. Thus each settler arrived in his new home not as an individual but as a member of a group, and he had around him friends, possibly relations, from his old district, or, at any rate, men with whom he was connected by the ties of common social customs and habits. This organisation immensely facilitated the execution of the preliminary work to which I have alluded, and was in no small measure the cause of the astonishing rapid success of the peasant settlements. The principle is less applicable to yeomen grantees and still less to the capitalists, and this difference may, to some extent, explain the less rapid success of the settlers of these classes.

It was fortunate for the Punjab that within easy reach of the Chenab, the first colony opened for settlers, there were districts densely populated with some of the finest husbandmen of India where the *morcellement* of the land had been carried on to great lengths. A great land hunger had already established itself, and the peasantry of those districts was composed of fine husbandmen of the very class that it had been decided to recruit for the new colony. It was to these districts, therefore, that the Colonisation Officer first turned for his settlers. As was natural, some hesitation was shown at first, but when once a crop had been harvested by the early colonists, the success of the venture was assured. The Colonisation Officer was thronged with eager applicants hurrying to share in the benefits already enjoyed by their more fortunate brethren. He was, of course, unable by himself to distinguish the good from the bad among this eager throng, and from the first he relied upon the Deputy Commissioners of the districts selected as recruiting grounds to chose the peasant groups for him. The system adopted was for the Colonisation Officer to send to the Deputy Commissioner information concerning the area available for distribution to inhabitants of his district, the caste or tribe, and the number of settlers required. It was usual for the Deputy Commissioner to send one or two leaders in the first instance to spy out the promised land. If their report was favourable, as it almost always was, volunteers were forthcoming in numbers, and the Deputy Commissioner sent the selected men in a body to the Colonisation Officer on a pre-arranged date. They were then given their allotments. Selection of the higher classes of colonists was generally subject to the sanction of superior authority, and as a rule they arrived in the colony as individuals and not as members of a group.

The isolated position of Sind made the task of importing settlers somewhat more formidable. It was decided to reserve the greater part of the land available for colonisation from outside the province for settlers from the Punjab of the class that had made such a success of the Chenab colony. But, owing to the great distance of the promised

land from the homes of the pioneers, special arrangements had to be made, and, moreover, as the indigenous agricultural population of Sind is almost entirely Mussulman, it was thought best to confine recruitment mostly to followers of the Prophet in the Punjab. The Colonisation Officer first enlisted in his favour the services of one or two leading men of the selected classes who had made a success of their grants in the Chenab colony, and who, therefore, had experienced and overcome the difficulties of settling in a new home under similar conditions. He brought them down to Sind at State expense, and showed them over the Jamrao lands. He then returned with them to their home districts, where by their influence he was able to recruit a sufficient body of suitable men, and as the settlers could not be expected to find their way to Sind unassisted, he arranged with the railway authorities for special trains which brought not only the settlers themselves, but their families, their cattle, their agricultural implements, and their household goods. After the first batch of colonists that had been imported in this way had settled down and reaped a harvest or two, it was found unnecessary to make special arrangements. The fame of the new canal soon spread, and colonists were able to find their way to the ground unassisted.

Hardships and Difficulties of the Early Settlers.

After his arrival in his new country the lot of the early settler was not free from hardship and difficulty. It was inevitable that in opening irrigation works of such magnitude small mistakes should occur. Land allotted on the promise of water was found to be uncommanded; the water would not flow over it by gravity, and the settlers had to be shifted to other parts. Another more frequent cause of hardship was that in many cases the soil which appeared to be fertile was found to be irresponsive to the early efforts of the colonists, and the Colonisation Officer had great difficulty in deciding claims for fresh allotments, for on the one hand all could not get land of the very highest fertility, as they would have liked, and on the other it was essential to make the early settlers prosper as quickly as possible. Then, again, though the tracts colonised were practically uninhabited, they were frequented by cattle- and camel-breeders, who resented the presence of the new-comers on their grazing grounds, and who made their resentment felt by stealing the cattle of the foreigners. Such harassment was most severely felt in the Chenab. Then, again, a number of bad characters found their way into the colony, even amongst the most carefully selected groups, and with the slackening of social restraints to which they were accustomed in their old districts, they took the more easily to evil courses. Moreover, the exposed position of the early settlers in their temporary shelters invited attack by thieves, and the Chenab colony at any rate was for some years at the beginning distinguished for a heavy record of serious crime.

Disease, too, was not absent. The opening up of ground that had lain undisturbed by the plough for centuries, and the pouring over the land of water gave rise to malarial fever of a virulent type, and at some seasons of the year the inhabitants of whole tracts were in the early days prostrated and unable to do any work at all. I have myself, at the first harvest after the opening of the Jamrao Canal, ridden through hundreds of acres of ripe crops ready for the sickle which were being destroyed by the birds or the beasts because scarcely a single individual was able to leave his bed on account of fever.

The Jhelum colony was particularly unfortunate. For in the third year of its existence not only were the autumnal fevers of a very severe type, but in the following spring the settlement was devastated by a virulent outbreak of plague. The new colonists fled to their old homes, and could only with difficulty be persuaded to return when the outbreak had abated. The Colonisation Officer himself nearly lost his life in the epidemic, and his most experienced Indian assistant was one of its early victims.

Perhaps one of the most formidable difficulties of all was connected with a supply of drinking water. When the canal was flowing, good water was, of course, obtainable. But Government channels have to be closed for considerable periods so as to allow the engineer to carry out his system of distribution, and once a year the water has to be shut off from the whole irrigation system for a considerable time to allow of repairs and clearances to the main channels. During such periods the early settlers were often in great straits and the authorities anxious. In the first instance the difficulty was got over by allowing the villagers to fill from the canal tanks which they were urged to excavate. The persuasive powers of the Colonisation Officer were often

taxed to the utmost to get these tanks dug; threats and even compulsion of a mild sort had not unfrequently to be resorted to. At best, however, even when tanks are reserved for men and cattle separately, a tank is an insanitary source of drinking water for human beings. As soon, therefore, as the settlers had settled down and begun to prosper, each village was urged to provide itself with a well for drinking water. Government advanced one-half of the cost and the remainder was raised by the villagers from among themselves. I find that in the Chenab colony almost every village has now its own drinking well.

In all these matters the colonists found a sympathetic friend in the Colonisation Officer. Water-courses were re-aligned or improved wherever necessary; exchanges of land were readily given when the first allotment was found to be uncommanded or really infertile. Special measures were taken to prevent cattle theft; and here I may mention that the best method of prevention was to give the thieves themselves land to cultivate. Not only was the nuisance thus mitigated, but these graziers, who had had no experience of cultivation, soon settled down to their new occupation and are now reported to be almost as fine cultivators as the skilled peasant with centuries of agricultural tradition behind him. The police administration was strengthened and the statistics of crime became more normal.

Thus, in a thousand different ways, the Colonisation Officer attended to the wants of the settlers, and helped them to tide over the hardships of the first years. Every colonist who imagined he had a grievance of any sort, turned to him for assistance and advice. His office was daily thronged with malcontents, and it required immense patience and great tact to listen to all, and send them away satisfied. Of course, there was some whom nothing would satisfy, and desertions were common in the earlier days of both the Chenab and the Jamrao, but the number of the desertions bore only an infinitesimal proportion to the total number of the settlers.

Laying out New Villages.

In short, the great majority of the new-comers soon settled down in the new colony, and threw in their lot definitely with it. With their increasing prosperity came the desire to build substantial houses, and it was one of the early duties of the Colonisation Officer to plan out a village site in which the settlers could make themselves comfortable according to their own ideas, and that would at the same time conform to the elementary rules of Western sanitation. A new plan for a model peasant village is reproduced below (Fig. 2). The plan varies, of course, with the class of colonists in each village. For a village inhabited by peasants, it is essential to adopt a village plan which would afford light and air everywhere, but closed in as far as possible from the outside as a protection against thieves. Each landholder should have a separate site, extensive enough to contain not only a dwelling-house, but a cattle-yard and a grain store, while a separate site, somewhat apart from the main body of the village, must be reserved for the lower castes.

The plan reproduced was first devised for the Chenab colony, and has been adopted with minor alterations for other colonies. Each landholder was given a plot 120 by 80 feet. The headman probably had two. Four shop sites were provided. A central plot was reserved for Government use which serves the purpose of the common meeting place for all, and separate parts of the village are reserved for artisans and low castes. The main roads are 80 feet and the side roads 40 feet in breadth. In order to afford protection the exterior sites were allotted first.

This model is subject to variation to suit the requirements of different classes of settlers. For a village inhabited by yeomen or capitalists each grantee requires a site capable of accommodating not only his own household, but his tenants and their families. Again, grantees, who are bound by the terms of their grants to maintain camels for Government service, require a different type of settlement, in which the outer boundaries are occupied by the dwelling-houses, thus forming a spacious walled enclosure, in which the camels can be tethered in lines.

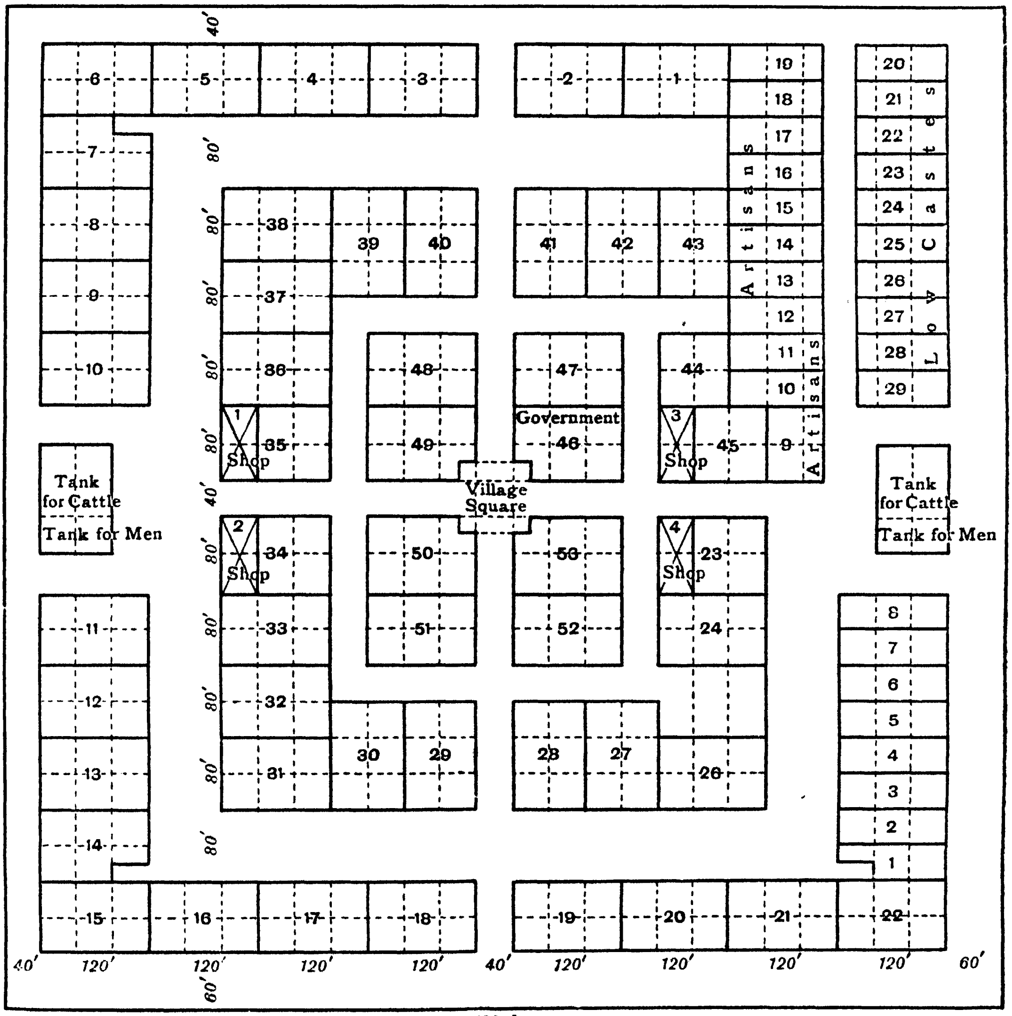
Village Sanitation.

In the plan the tank is a prominent feature. But as I have already explained this source of drinking-water supply is gradually being abandoned everywhere for the more sanitary well, but a tank will be retained for the use of the village cattle and other live stock.

In other ways, the sanitation of the village sites has been attended to. Manure is stored outside the village site. Hollows likely to retain putrid water are being filled up, and the Colonisation Officer of the Chenab colony, writing in 1902, was able to say that the people

themselves were beginning to take an interest and pride in the sanitation of their villages. In some parts of the colony there has already arisen a state of rivalry for the possession of the smartest and cleanest village site, and the people themselves maintain sweepers, whose sole duty is to keep the streets and lanes clean. The matters. In the main, however, the Punjabi peasant colonists reproduce replicas of their own home system. Headmen have been appointed by Government, and are rewarded by the allotment of an additional square of land for cultivation, in addition to the usual percentage on collections received in the

FIG. 2.



1100 feet

Government has recently made annual grants for the promotion of good sanitation. Thus these colonies may in time afford conspicuous examples of good village sanitation, which may serve as models for sanitary administration in other parts of India.

VILLAGE ORGANISATION.

In other ways the colonists have showed themselves open to new ideas in village Punjab. In a colony where to some extent every one considers himself as good as his neighbour, these useful officials do notpossess the prestige which attaches to the office in an old village with its ancient traditions. But where the principle to which I have alluded prevails, viz.: populating each village by a group bound together by the ties of kinship or caste, and where the office has been given to the leader of the group, the headmen still

possess real power and influence, and are able to carry on their duties efficiently. In Sind, however, where home influences are more remote and where to some extent the principle has been disregarded, the headman system shows signs of breaking down partly on that account and partly for the reason that the system of revenue management in Sind has never recognised the headman to the same extent as has always been done in the Punjab. Apart from this, however, the internal organisation of the new villages is, even in Sind, modelled closely on the home system. The colonists bring their carpenters, blacksmiths, potters, water-carriers, washermen, and the like, partly because they find them more trustworthy than outsiders, but mainly on account of the very large and hereditary part which these menials play in the social life of a peasant village, for, in addition to carrying on their own occupations, all have special duties or privileges at birth, marriage, and funeral ceremonies.

I have already shown that the importance of recognising this factor in the colonists' life was given effect to in planning the village site, but they were encouraged more especially by the reservation of a square or two of cultivable land in each village in which each is allotted a few acres for cultivation under the supervision of the headman of the village. No permanent rights in this area are granted to individuals, but the headmen allot from harvest to harvest to each artisan or menial working for the colonists generally a plot for cultivation. It was feared that this plan would fail, but up to the present no formidable difficulties have arisen, and in Sind, at any rate, it has been found to work well.

Scarcity of Labour.

Notwithstanding these arrangements, however, all three colonies have suffered to some extent from a scarcity of agricultural labour. In the Chenab the low caste Dedhs from the surrounding districts supplied the want at first and occupied a very strong position, but in later years they have been ousted to a large extent by the relatives and caste fellows of the landholders themselves. The initial years of the Jamrao synchronized with a period of famine in the adjoining parts of Rajputana and immigrants in search of labour were plentiful. But the last year in Rajputana was a good one, and the colony is apparently face to face with a serious scarcity of labour. Indeed, complaints of difficulties in this respect are heard from all three colonies.

Some Social Changes.

While conforming in the main to their traditional village organisation, the colonists have not remained unaffected by their new environment. Thus in social matters, which are generally so rigidly ruled by custom, some curious changes are mentioned. For instance, the peasants of the Gurdaspur district of the Punjab, where burnt bricks are not regarded as auspicious building material, are now using them freely on the Chenab Canal in the construction of their houses; and Arian (Mussulman) women of the Jullundur district now consider voluminous trousers a necessary article of gala attire, while in their original home they are never worn. Again it is noted that the Sikh religion is making much headway in the colony, partly owing to zealous proselytism by retired Sikh pensioners of the native army who have settled in the colony. These are small details gleaned from passing remarks in official reports, and I have no doubt that the colonies will afford a field of interesting study to the ethnologist of the future.

Some Statistics of Material Prosperity.

We may now turn to a consideration of the material prosperity of the colonies. The Chenab colony, which is the oldest, presents the greatest degree of prosperity, and as it has been constituted a separate district, we have more complete statistical data for it than for the other two colonies. I have, however, no intention of inflicting upon you a long series of figures, and it will be sufficient to give the broadest statistical results. The last census of the Chenab colony, taken about nine months ago, showed a total population of 858,000, and it was computed that in 1903 the colonist had exported produce by rail to the amount of 2¾ millions sterling, a figure which must be greatly exceeded by now. The area irrigated annually has risen in 10 years from 270,000 to nearly 2,000,000 acres. Taking all three colonies together the latest available statistics for 1905-06 show that the area supplied with canal water was over 2½ million acres, and that the total value of the crop raised was at a very low estimation over 4 million sterling. This last figure is based on the official estimate of the out-turn of crops, which is notoriously

below the mark, and I think it may be safely said that the total value of the crop was nearer 6 millions sterling, and as the gross capital cost of all three irrigation systems was somewhat less than 3½ millions sterling, the value of the crop raised in that one year was almost double the capital cost of the works. The value of the land in the hands of the colonists has increased enormously in value. Auctions have from time to time been held and we find that agricultural land that at the beginning of operations on the Chenab fetched under £3 an acre will now sell for as much as £20 or £30.

COMMUNICATIONS.

These figures naturally lead to a consideration of the equipment of a colony in its commercial aspect, the provision of means of communication and the construction of towns and marts. As regards internal communications, it has been the custom to reserve broad strips of land 60 feet to 80 feet wide for main lines of highways, and strips of lesser width for inter-village and field to field communications. Such strips were reserved to the State from the first, and considerable progress has been made in metalling the main roads in the Chenab colony and in bridging all roads throughout. In a country intersected by a network of irrigation channels, the provision of bridges over all classes of road is a matter of serious consideration. In the Jamrao, the problem was solved by carrying every road as outlined over every water channel met with before settlers appeared, and part of the expense was subsequently recovered from them. But on the whole I venture to think that the provision of good means of communication throughout the colonies has not kept pace with their development. In all three road metal is unobtainable, except at great expense, as it has to be brought from great distances, and I have always thought that they presented a splendid field for the construction of light feeder railways, which ought to prove very remunerative. All three are well served by branches of the North-Western Railway, but the question of easy internal communication and the rapid transport of agricultural produce to the stations on the main lines of railway still requires consideration.

TOWNS AND MARTS.

On the other hand, the problem of providing towns and marts as collecting and distributing centres for the trade of the colonies, has been very successfully dealt with. The chief town of each colony is at the headquarters of the local administration, Lyallpur—in commemoration of a famous Lieutenant-Governor of the Punjab—being the name given in the Chenab colony, and Sargodha in the Jhelum colony, while on the Jamrao the headquarter station is at the old town of Mirpur Khas, which even before the opening of the canal was a place of some importance. At each of these centres it was necessary to provide not only for a new trading town but also a civil station for the officers of the colony. The map below gives a good idea of how such a town and station has been laid out. It represents Sargodha which is the last of its kind. (Fig. 3.) It will be observed that this plan provides not only for a European settlement and a native town both conveniently situated for the railway station but also for public offices, recreation grounds, and public gardens.

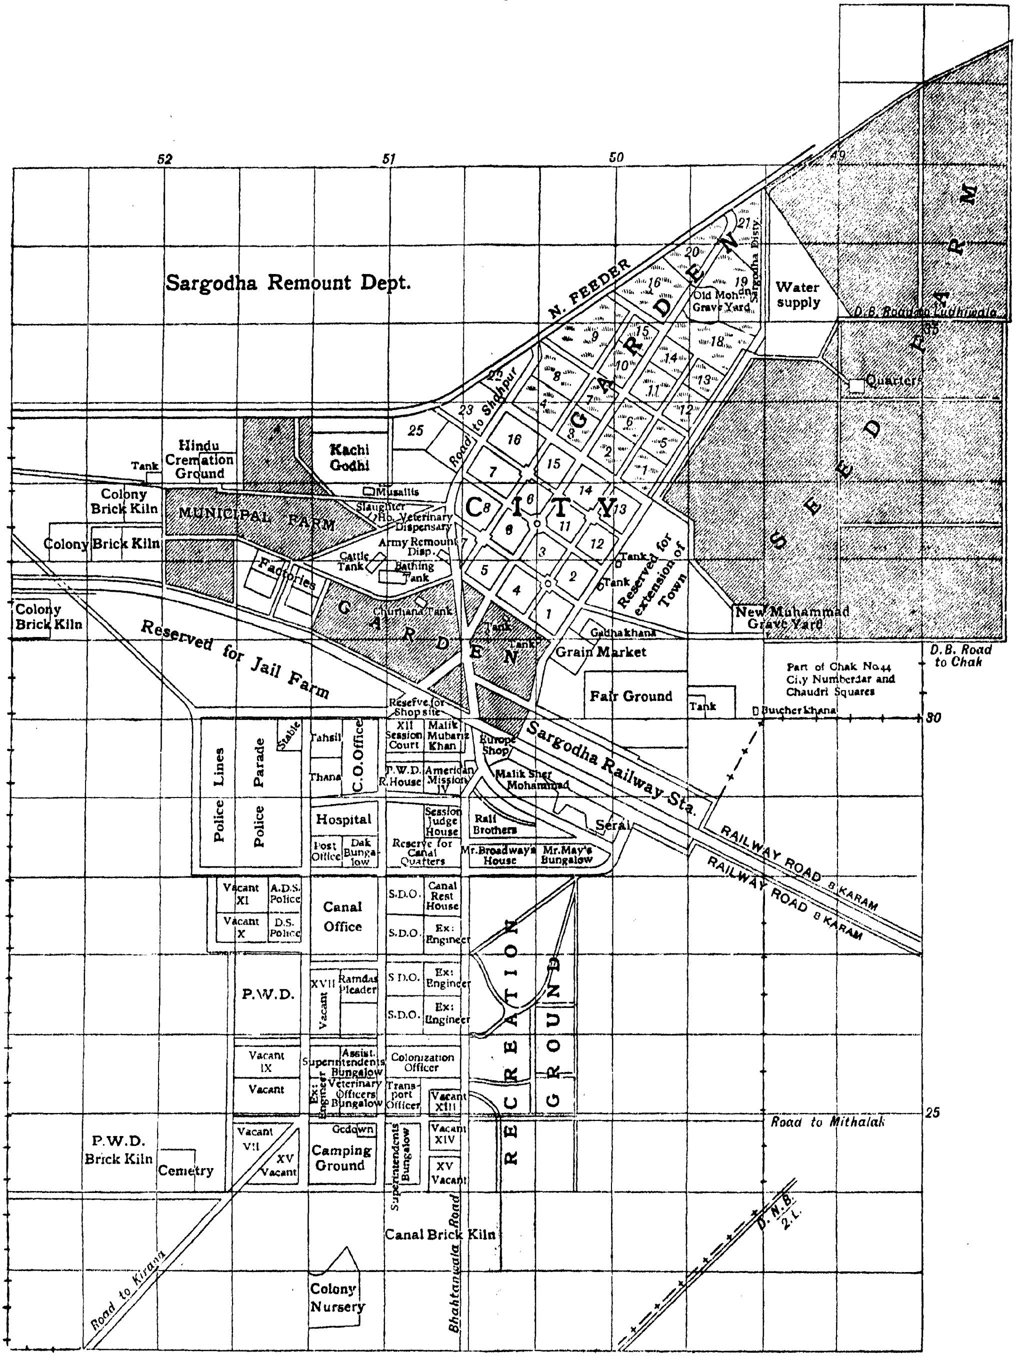
The planning of the native towns themselves gave scope for much ingenuity and thought. The way in which Lyallpur city has been laid out is shown in the map below. (Fig. 4.)

You will observe that Lyallpur is based on an octagon, a shape that has been found to give trouble when the town expanded beyond the limits at first fixed for it. In other more recent towns the square has been adopted as the basic figure. All, however, have been planned so as to provide wide straight bazaars, spacious grain markets, sites for public offices, schools, hospitals, and veterinary dispensaries, and other requirements of modern town life.

In addition to these chief cities each colony possesses a number of smaller towns, mostly situated at railway stations. These have been laid out on less ambitious lines than the chief cities, and are chiefly intended to provide collecting centres for the export trade of the neighbourhood. The magnitude of that trade in one article alone is reflected in the exports of wheat from Karachi, the value of which has risen from 2¼ millions sterling in 1898-99 to 8 millions in 1904-05.

In giving out building sites in all colony towns, whether by allotment to applicants as in the beginning or by putting up the lease to auction as is now done, strict conditions are enforced as regards structural and sanitary requirements. All the buildings in the main streets and bazaars are required to be of burnt brick, and designed in accordance with a uniform pattern, so that Lyallpur for instance

FIG. 3.



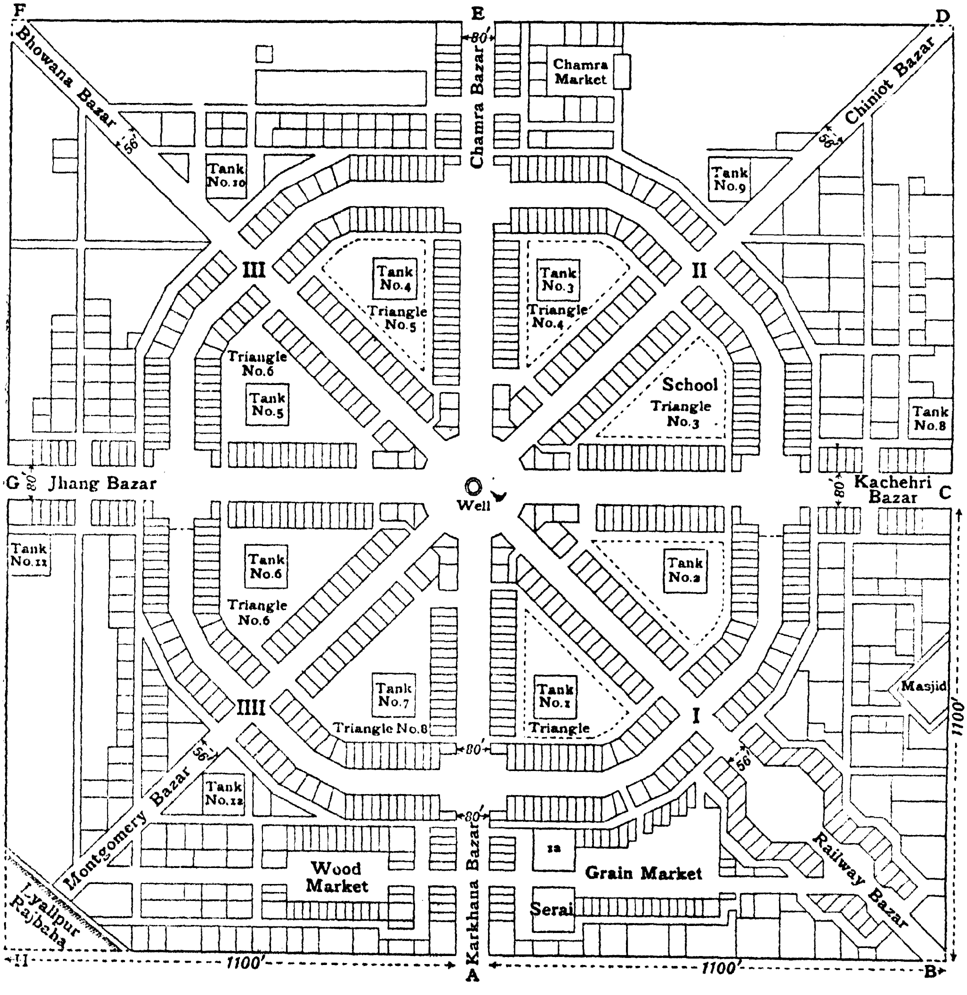
presents a striking and handsome appearance. The leases of the plots have fetched in most cases very good prices, and the State has provided liberally for the equipment of the towns with public works and for sanitary development by assigning for the purpose a sum equal to the proceeds of the sales for a considerable term of years. These assignments are generally placed at the disposal of the local governing body on conditions that ensure their disbursement only on the objects for which they are intended. The progress of

most of these towns has been strikingly rapid. I see that Lyallpur, which was founded in 1895, had in 1901 a population of over 10,000 people, and when I visited it about that time it was an exceedingly busy place with an enterprising and energetic population.

Agricultural Improvement.

Nor has the enterprise and energy which characterise the townsmen of the colonies been absent from the agricultural settlers. The opening up of new ground, under new conditions, has done much to shake the traditional conservatism of the Indian agriculturist, and this fact makes the new colonies the most hopeful fields for the improvement of agriculture by scientific methods. As the Government of India have now been able to set apart considerable sums for the promotion of agricultural education, and the organisation of thoroughly equipped agricultural departments all over the Indian Empire, the development of scientific work on practical lines should be most rapid in these new colonies. The Government of the Punjab has selected Lyallpur as the site for the new Agricultural College and Research Station now in course of erection, and a number of experimental farms have been established in all the canal colonies.

Fig. 4.



A large amount of preliminary work has been done. The economic conditions of the colonies themselves are favourable for the introduction of improved agricultural methods since the scarcity of field labour is forcing the farmers to look to labour-saving apparatus

as a way out of the difficulty. For instance, reaping machines are already in use in the Chenab colony for dealing with its enormous wheat crop, and in many other ways the agricultural industry is being improved under the direction of the State Departments of Agriculture. I shall give only two particular instances. On the Jamrao, Egyptian cotton has been successfully acclimatised. The lint produced has been pronounced to be equal to the best Egyptian product in fineness and length of staple, and has realised very remunerative prices. Last summer an area of 6,000 acres was sown by the more enterprising landholders, prominent among whom where the Panjabi settlers, and although just before the harvest the crop was almost completely ruined by boll-worm, what was saved was of fine quality and realised good prices. In the Chenab colony, important work has been done in the acclimatisation of both Egyptian and American cotton. Here again, repeated destructive attacks of boll-worm have prevented absolutely assured results being obtained. The Agricultural Department is very hopeful of devising some effective means of combating this destructive pest, and when this difficulty has been overcome, India will possess a splendid supply of fine long-stapled cotton, which cannot fail to have important effects on her own cotton manufacturing industry, and on that of this country.

Financial Results.

Before closing this paper, it may be of interest to notice briefly the financial results to Government of these great undertakings. Quite apart from the greater prosperity of the people actually settled in the colonies, from the increased food supply made available in an empire parts of which are frequently afflicted by serious failure of crops, and from any additional revenues which the State may gain from income tax and railway receipts, the net revenue due to irrigation on the Chenab in 1905-6 was £391,000, on the Jhelum £10,800, and on the Jamrao £39,300. The agricultural year for which these figures are compiled was a disastrous one in the Chenab colony, where the cotton crop was almost entirely destroyed by boll-worm, and extensive remissions of State demands were given. Taking the figures as they stand, however, they represent in the case of the Chenab Canal a return of 20 per cent., in the case of the Jhelum Canal of 1 per cent., and in the Jamrao Canal of 7 per cent. on the capital invested in the irrigation system of each. The poor financial result in the Jhelum colony is, of course, mainly due to the disastrous plague that overtook it in its early years, and to the fact that a large number of settlers are still receiving remissions. All three systems are capable of further development, and the net return to the State, which goes, it should be remembered, to lighten the burden of taxation in India generally, will rise with steady persistency.

In concluding this paper, I would like to remark that in writing it I have endeavoured to avoid controversial topics, purely technical matters and the expression of personal opinion. My aim has been to sketch in the broadest outline the work that has been done in the establishment of the great irrigation colonies in India. I venture to think that the account presents a piece of administrative achievement of the highest order, and I would remind you that the work has been accomplished by whole-hearted co-operation and devotion to duty, not only on the part of the Colonisation Officers and their staff, but also on the part of the Irrigation Officers and their establishment, and finally by the patient steady industry of the great mass of the Indian settlers.

DISCUSSION.

The CHAIRMAN, in opening the discussion, said it must be remembered in approaching such a topic that while they had undoubtedly in India achieved the greatest possible benefit to the population by the carrying of water to arid districts, they had not been the pioneers in the movement. Their more immediate predecessors, in the control of the greater part of India at any rate, the Mohammedan emperors, were from their earliest settlement in the country immensely interested in the irrigation of land; and he thought it was at least worth while recalling that, to whatever part of the world the Mohammedan race had carried its doctrines and its conquests, the one great feature of its system of administration had been the irrigation of the land over which Moslems had spread themselves. That was seen in Europe in those interesting and gigantic remains in the south of Spain; it was seen in many places in the north of Africa, and it could be seen, although in an imperfect state, in the east of Europe. It was quite true that while England had succeeded in developing the ideas which the Mohammedans initiated, we had not in this particular case of irrigating parts of India actually followed the lines which they drew up for their great canals and water schemes. The author, in the concluding portion of his paper, had drawn attention to the profits which had accrued to the

State as the result of successful experiments in India in irrigation, pointing out that the Government of India was the better off by half a million a year from the profits of the enterprises. It should, however, be mentioned that, although the enterprises in the Punjab were perhaps the greatest part of the undertakings on which the Government of India had embarked, they did not represent much more than one-third of the whole of the profits which accrued to the taxpayers of India from the money, industry, and skill which had been employed in irrigating the arid places all over the great continent of India. He had been particularly interested in the remarks the author had made with regard to the area which the Government of the Punjab allotted to each individual cultivator. Mr. Robertson had stated that 27 acres of land represented the amount upon which it might be assumed that an individual could live in comfort and decency according to the ideas of the country. An almost endless speculation might be embarked upon as to the amount of increase which was possible in the population of India if the whole of its sterile lands could be settled in the way the Punjab colonies had been; but it must be of the greatest importance to the State that the surplus population, which increased very rapidly in India, could be provided for by making provision, within the limits of the Indian Empire, for those people who were now crowding and overcrowding a great many districts. The second point which interested him greatly was that the author had mentioned the attention to sanitation which was becoming apparent in the villages. Nobody who was connected with the Government of India, either on the spot or at home, could have failed to be struck with horror and pity at the unceasing spread of plague in India. It had claimed nearly three-quarters of a million of victims this year already, and there was unfortunately a steady increase in the number of cases and of fatalities from year to year. He thought with only one exception the figure had grown steadily for about 10 years. All the efforts of the Government of India were devoted to grappling with that attack, but the greatest obstacles were the habits of the people themselves, and their failure to see the necessity of paying attention to sanitary matters. Until the prejudices of the population could be overcome, the ravages of plague could not be stayed; and, therefore, anything which pointed, in however small and tentative a fashion, to the understanding of the people themselves of the necessities of sanitation must be welcomed by all who were interested in the country. The author, perhaps wisely, had not dealt with the question of the incidence of the charge laid by the Government upon the cultivators for the benefits afforded. It was impossible to shut one's eyes to the fact that some, at all events, of the discontent which was reported as being prevalent in India at the present moment was connected with the assessments by the Government of the charges upon the land. Nothing would have interested him more than to have learned at first hand from one who was actually connected with the local administration of the colonies in what way and to what extent the charges were levied upon the colonists. It mattered little whether one turned to India and looked at the irrigation colonies, or to France and looked at the vine-producing districts, but wherever the cultivators of a country thought they were over-burdened with taxation in respect of the products of the land, discontent and irritation would be found; and it was to the advantage of the home Government and the Indian Government to inquire into and ascertain the causes of what might be called the unrest, and the measures which might reasonably and properly be taken to benefit the people who were cultivating the soil. He desired, in conclusion, to draw the attention of the public to the great task which the engineering staff of all kinds in India had undertaken on behalf of the Government. He could imagine no career more interesting for any young man—whether it was the most remunerative of all he did not know—than that of being a civil engineer in a great country like India. It was unquestionable that the British achievements which would be most deeply engraven in the soil of India were the railways and canals which had been created in that country, because means of communication and means of production were the essence of the life of the people of all countries.

Sir EVAN JAMES, K.C.I.E., C.S.I., remarked that it so happened that, while he was Commissioner in Sind, the Jamrao Canal was not only designed but carried out; and he had the pleasure of obtaining from the Government the services of Mr. Robertson as Colonisation Officer. India owed a great deal not only to Sir Dennis Fitzpatrick, to whose brilliant intellect and great common-sense the scheme for laying out of colonies was mainly due, but to the Colonisation Officers. The author would be the first to acknowledge his indebtedness to Major Popham Young, who was the first practical coloniser in India. The work done by the Colonisation Officers, of whom the author was one of the finest, was such as the audience could not possibly realise. For instance, in Sind the author was confronted with upwards of 1,000 square miles of absolutely waste country, and there was an old saying that there was only a sheet of brown paper between Sind and the infernal regions. Regardless of climate, Mr. Robertson had, with the aid of his Indian surveyors, surveyed the whole of that vast area, and divided it up into 1 acre patches. Every now and then a simoom occurred which obliterated the boundary marks traced on the ground, and the work had to be done over again. Mr. Robertson allowed nothing to discourage him, however, and the work had been carried out in the most admirable way. He laid stress on that point, because when he left India and went to East Africa he found a most terrible oversight had been made. Colonists had been invited to places very much resembling

Sind in their level character, with very little water, before marking out one single plot of ground, not even a farm or an area such as would be called a village or a parish in England. From that evil the author saved Sind as Major Popham Young saved the Punjab. Then the labour in choosing and settling the colonists needed untiring energy, patience, and tact. He desired to mention two points in the agreement with the colonists which he thought were of the most vital importance. One was that no settler, excepting the capitalist, was allowed to mortgage or alienate his land. During the last century all Indian officials had been impressed with the force of Arthur Young's magic of property maxim. Everybody thought the ryot would profit by being given absolute power and dominion over his land, but for the last forty years they had been trying to take it away again. Unfortunately the ryots did not know their own interests, and he supposed that in many parts of the Presidency of Bombay half or a third of the land which had been given to the ryots, on which they and their ancestors had lived for a couple of centuries, had passed from their hands owing to their want of intelligence and to the chicanery of moneylenders, as alien to the country as a Polish Jew would be in England. He remembered reading the Proceedings of the Duke of Richmond's Commission on Small Holdings in England, and some of the witnesses said that if small holdings were to be a success in England the power of alienation and mortgage ought not to be allowed. Various Commissioners suggested that that was a very strong measure, but experienced witnesses maintained that unless that system were adopted in England small holdings would be a failure. He was, therefore, glad to see that, in the proposals which were now before Parliament, small holders were not to have conferred upon them the fatal gift of power to mortgage and alienate. Another very excellent provision was that of preventing the holder absenting himself from his land; and to carry that provision into effect a man of very strong force of character like the author was needed. If there was the smallest reason to believe that an owner went away with the intention of living in his own comfortable home on the remittances which his agent obtained from tenants or sub-tenants, then the property was absolutely resumed. That might seem rather a harsh and arbitrary proceeding; but he asked the audience to consider what Canada, Australia, or the United States would have been like now if, when colonisation began, the colonists had not settled on the land, but had returned to England and allowed their agents to send them remittances obtained from mere labourers on the land. That was one of the greatest points in Sir Dennis Fitzpatrick's rules, which he was thankful to say had worked thoroughly well. With regard to what had been said about cotton experiments, he desired to say that the late Duke of Argyll, many years ago, sent some Scotch gardeners to parts of India for the purpose of trying to improve the cotton staple. After twenty-five years the experiments in Sind were abandoned because they had not been successful. Personally he should not like it to go out to the world that long staple cotton was going to be a success in India. Of course the boll-worm might be extinguished, but his impression was that certain products suited certain countries, and that they must not depend, any more than they did in 1864-5, on getting the best cotton from India. He ventured to think that few more interesting papers had been contributed to the Society of Arts than that read by Mr. Robertson.

Sir FREDERIC S. P. LELY, K.C.I.E., C.S.I., imagined that very few present would have suspected, if it had not been disclosed by Sir Evan James, that the author of the admirable paper had been himself a most efficient and successful colonization officer, so great had been his modesty. What Mr. Robertson had said with regard to laying out a village reminded him of an experience of his own many years ago in the district of Ahmadabad, where a flood had carried away ten or twelve villages. He was entrusted with the work of rebuilding them on new sites, and remembered sitting down and evolving out of his own head what, in his youthful complacence, he thought a most admirable plan adapted to meet every requirement. He sent the plan the next day to be carried out, and subsequently was taken aback by a crowd of the villagers coming and casting it at his feet and saying it would not do at all. They pointed out that a good many of the houses were projected to face the East, and although they did not say so in so many words they pretty clearly intimated that he was an exceedingly simple person not to know that in that quarter there dwelt a demon, who would most certainly enter their houses and give them no end of trouble if doors and windows were placed in that direction giving him ingress. Although the laying down of a village did not seem to be a very complicated matter as shown on the screen, it presented far more difficulties than appeared at first sight. He thought all would agree that the description of the work given by the author presented a signal example of how much work was to be done in India, and how the work which sank deepest into the life of the country was that done face to face with the people. The native of India did not care much for principles or political theories; in fact he did not know anything of them. What he wanted was moderate taxation, freedom from harassment, and his own institutions, or at any rate the spirit of them, and under or over them all a sympathetic officer who understood him. He desired most heartily to endorse Sir Evan James's remarks with regard to the land tenure question. He was very pleased to see that an untrammelled experiment was going to be tried of giving the people absolute possession of their land, but at the same time preventing them playing ducks and drakes with it. Indian officials had been

a very long time in coming to see that the absolute ownership of the land and the absolute power to transfer had been a burden to the people of India too great to be borne; it merely made them the victims of money lenders. He did not desire to say a word against money lenders, but when such people saw the land in the hands of people who were only too willing to part with it for a mess of pottage, they naturally tried to get it for themselves, and that had been in the main the reason of the indebtedness of the people of the country of which so much was heard. They had lately been told in *The Times* that the very colonies which, to their minds, were triumphs of the British engineer and administrator, had been made the handles of sedition and discontent. He did not know enough of the circumstances to be able to suggest how that arose, but if the author could explain the position to them he thought all present would be grateful.

Mr. H. S. LAWRENCE, I.C.S. (Director of Agriculture, Bombay), remarked that the author had very wisely avoided all controversial topics, but he would not follow Mr. Robertson's example, his object being to gain knowledge on certain debated matters. The first point to which he desired to allude was a very important matter regarding the future development of the canals, which was a subject of discussion amongst experts in India, and on which they would be very glad of any light which the members of the Society might be able to throw. The question was, What was the effect of irrigation on alkali soils? The alluvial deposits of the rivers from which these canals were derived contained large tracts of alkali, and, on the one hand, it was alleged by agricultural scientists that the effect of the advent of a permanent irrigational canal would be to draw the alkali from the sub-soil to the surface, and to render large areas infertile. On the other hand, the irrigational officers of the Punjab stated that their experience was directly the contrary—that the alkali was driven down by ample irrigation, and could be washed out of the soil entirely. That point required investigation, because as yet no competent agricultural observers had had time to consider it thoroughly; but as regards the province of Sind, the Bombay Government were anxious that it should be fully examined. Fortunately they had secured the services of a most eminent scientific officer, Dr. Mann, than whom nobody could be more competent to advise them in this task. He had been interested in the author's reference to the agricultural improvements which were in prospect in the colonies. Those improvements chiefly turned on the novel character of the irrigation which was provided by the perennial canals. In Sind, and, he believed, in the whole of the Western Punjab, all the old canals were inundation canals; and in Sind at present 90 per cent. of the cultivation was dependent on inundation canals, *i.e.*, water was only available while the snows were melting in the Himalayas and the rivers were in flood, from the months of May to November. So brief an agricultural season necessarily ruled out of the agricultural programme all such valuable crops as wheat, sugar cane, oil seeds, long staple cotton, and spices, which either required a longer period of growth or else a more temperate climate in the winter. But the perennial canals had entirely revolutionised the agricultural system. It would take time for the colonists to change their ideas and to learn the most efficient management of land and water in those new conditions, but the great growth of wheat exports from India of recent years was largely due to the irrigation colonies, and there was no doubt that their present prosperity was only the early promise of what was to come. In passing, he desired to allude to the important projects which were now under consideration for the construction of barrages on the Indus similar to those which had been constructed on the Nile. Those barrages, if they could be constructed—and engineering opinion was very hopeful on the point—would have the effect of adding six million cultivated acres in Sind alone, and would also convert all the existing inundation canals in Sind into perennial canals. The effect on the increase of valuable crops in Sind would be enormous. The author had stated that the exported produce of the Chenab colony in one year amounted to 2¾ millions sterling, and that the net irrigational revenue was less than £400,000. It would be interesting to learn, in view of the recent experience to which the Chairman had alluded, exactly what was the proportion of the total payments of the colonists to the value of the produce reported. So far as he was able to ascertain, it was something less than 20 per cent.; and it was possible that, as was the practice in most parts of India, the cultivators reserved their food supply for themselves first and exported only the surplus. At a time when projects for securing a greater measure of control over land were before the public, it was interesting to reflect upon the position of the Government of India as illustrated by the irrigation colonies. That Government might be described as a Radical autocracy. It was often denounced as an autocracy, but its Radical and Socialistic qualities were seldom recognised. In the case under discussion a good example of that was seen. The State was the absolute owner of vast tracks of sterile desert, and, by utilising the mighty reservoir of the Himalayan snows, transformed that desert into a smiling, fertile cornfield. Great benefits were conferred on the cultivators, and a share of that produce, very far below an economic rent, was taken from them, and went to lighten the general burden of taxation in India. These principles were identical with those which governed the action of the State in all departments in India, though one did not often see so clear an example of the assertion of the right of the community to a full share in the surplus values created by the community. But it was a curious phenomenon to observe, that amongst the gentlemen who advocated those principles for adoption in home

politics some were to be found who cast at the Government of India in such matters the most vigorous and hostile criticism. Some gentlemen who anathematised the principle of private ownership of land in England supported movements in India, the object of which was to restrict the rights of the State over land. Again, men who strenuously opposed the domination of propertied and landed interests in England could be found working, no doubt unconsciously, to hinder and obstruct that Government in their efforts to protect the peasant and the labourer from oppression and spoliation. It would be well if those gentlemen, who understood so little the application of their principles to India, could be induced to study the history of the irrigation colonies, when they would be surprised to find that the very objects which were aimed at by advanced schools of thought in this country were already, to a great extent, secured by the land systems of India. No doubt mistakes had been made in the grant of excessive power over the land to people who were not prepared to utilise it to the best; but, taken on the whole, those systems gave to the people the magic right of property which converted sand into gold, and at the same time had been successful in safe-guarding for the State the communal rights to increments of value.

Mr. J. S. Beresford, C.I.E., M.Inst.C.E., remarked that there appeared to be considerable misapprehension regarding the Square Survey, which in the Punjab was entirely the work of the Irrigation Department, carried out before the Colonisation Officer had been appointed. It formed the basis of the large contour maps of the tract, as explained in Mr. Sidney Preston's paper of 1902. The Colonisation Officer afterwards had the original squares sub-divided by parallel ridges into plots or fields of about one acre, an important work in itself and one difficult to carry through in practice owing to the colonists usually making the ridges crooked. Referring to the produce obtained from the irrigated land, he remembered in 1897 having experiments made with regard to the produce in the Chenab colony, where the finest wheat crops he had ever seen were then grown. Eighty bushels an acre in some cases were produced. It had been said in the paper that long staple cotton had been grown in Sind and the Chenab colony, but nothing had been mentioned of the produce, upon which everything depended. In Egypt the average produce from an acre was 600 lbs. of ginned cotton, worth from £15 to £20, but he understood the produce in the irrigation colonies in India was probably only a quarter of that amount at present. Compared with Egypt, with which he had had an intimate connection since he retired from the Indian service, the produce of cereal crops in the Chenab colony was better than that of Egypt, and there the rents varied from £6 to £9 an acre, while £4 an acre was being given for one crop of wheat in a large area which had been recently brought under cultivation; it was very hard to understand why complaint should have been made of excessive taxation in tracts irrigated by perennial canals when one remembered the very low rates that existed in India. He had spoken to settlement officers who had been in Egypt, and they were much puzzled with the comparison. No mention had been made in the paper of the railways that had been constructed, without which it would not have been possible to carry away the products. Referring to the question of sanitation and wells, the first difficulty was to get wells in which the water was drinkable. When Lord Curzon visited the colony in 1899, at Lyallpur, the large central well was one of the show places of the town, but the fresh water being pumped from the well was supplied from a canal channel. The well water, generally, was of a brackish nature, although he believed its quality had improved since those days. The wells were then 100 feet deep, but owing to percolation from the canal they had now probably risen and become sweet. The question of the deposit of salt was dealt with largely in Egypt, there being vast areas which had been reclaimed by washing. In one big scheme, in an elevated tract, the reclamation was effected by washing downwards, by flooding the surface to a depth of three feet. It was found that all the deleterious salts were carried down, and all the soluble nitrates as well, and before a crop could be grown £1 an acre had to be spent in the provision of nitrate of soda and sulphate of ammonia. That, as far as he understood, was a process which was never adopted in India. In Egypt, no one expected continuous good crops without spending annually a pound or two an acre on artificial or other manure. He did not suppose, however, that the people in India could afford it at present, but if they obtained the land and water free for two years, as a start, they might be able to do so. The use of artificial manure was one of the questions which must be carefully looked into in the future. One point the author had overlooked was that it was difficult to separate the Colonisation Department from the Irrigation Department. When he was connected with the Chenab colony, there was only one Colonisation Officer and his native assistants, while at the same time there was a Superintending Engineer, and five Executive Engineers, with their complement of Assistant Engineers, five Deputy Collectors and a large subordinate staff, all engaged on maintenance of works, and on irrigation in the fields. It was essential that a large staff of trained engineers should be employed, and on the efficiency of that staff, on the careful distribution of the water, and on the general administration of the irrigation, the success of the scheme depended. Having regard to these facts he thought a stronger term than co-operation might have been used by the author respecting the work done. The Public Works Department

would highly appreciate the tribute paid by the Chairman to the Engineering staff.

Mr. R. B. BUCKLEY, C.S.I., M.Inst.C.E., in reference to the question of the present unrest in India being in any way due to the imposition of water rates, said he could not speak personally with reference to the irrigation colonies of the Punjab. He could, however, speak with very intimate knowledge indeed of a large system of irrigation in another part of India, where for several years he had to deal with troublesome questions something of the same nature as those which arose at present, where those who drew their supplies of water from the canals were constantly saying that their water rates were too high, and that they were being ruined. That system at one time did not use all its supply of water for irrigation purposes. Now, he believed he was right in saying that every year irrigation leases were refused to thousands of acres because there was not sufficient water to supply the demand. The people complained that their water rates were too high. The Government had raised the rates wisely but gradually, and he fully believed the people could easily pay double the rates they were paying at present. The cultivators took water for every acre for which it could be obtained; they clamoured for leases, and it was a remarkable fact that, although on that canal 250,000 individual cultivators were dealt with, and the water rates were collected from them individually, for the last four or five years there had not been one single rupee which was not paid at the date it became due. People who were complaining that they were being burdened with rates would not pay them so willingly if the price was higher than they could afford to pay. He, therefore, did not think much reliance could be placed on the complaint that the unrest was due to excessive water rates. It was difficult to appreciate the dimensions of the works which had been described in the paper. The author had stated that the three schemes in the Punjab commanded some 8,500 square miles, about 6,500,000 acres. That land had been entirely reclaimed from the desert; it was a new country with a new population, and the area was just about the same as the culturable area of Egypt. Administrators and engineers had created in India a new country as large as it had taken thousands of years of irrigation to make in Egypt. He thought the people of this country did not altogether appreciate the size of the canals. If the old records of Babylon were inspected it would be found that one of the monarchs described, in a cuneiform inscription which he placed some 2,500 B.C. on one of the monuments in Chaldea, how he had created a great irrigation colony there, 250 miles long, and 20 miles broad, or 5,000 square miles of country; he created, so he said, great rivers in the desert. The Chenab Canal was a great river in the desert. A great many people in this country formed their idea of irrigation canals from the canals they saw when travelling down the Great Western Railway, or in Regent's-park. Some of those present had no doubt stood on Staines bridge or Richmond bridge, and seen the Thames in flood, the waters spreading over the country on every side. tearing through the arches of the bridges, and flowing over the tow-paths. The Chenab Canal, at certain times in the year, carried about the same quantity of water as the Thames in flood. The men who had made those works had done well for India. The king who created great works in Babylon said at the end of his inscription, "I have given them fertility and plenty, and have made their homes the abode of happiness." The men who had made and administered the great works in India had done the same thing for hundreds and thousands of people who, but for these works, would have been poor and perhaps in want.

Colonel Sir COLIN SCOTT-MONCRIEFF, K.C.S.I., K.C.M.G., R.E., remarked that it was 48 years since he tried his 'prentice hands on the canals of India; it was 24 years since he finished with India, and 15 years since he left Egypt. Others who came after him narrated what was going on at present, and he could only read their reports and rejoice in their doings. In the early days, irrigation people were looked upon rather as faddists, and great doubts were expressed whether irrigation would do any good. Some people said it increased the fever and brought up the salts in the soil, but there were always a few staunch men who contended that the work must be a success. Such an idea as an irrigation colony was not then thought of; and it was a great pleasure to him, when he visited India six years ago, to see Lyallpur, an Eastern town that had been deliberately set out on sanitary principles. Probably his hearers were unaware of the fact that the centre of the town was planned upon the form of a Union Jack, in exactly the same way as Lord Kitchener had planned Khartoum. The Chairman had alluded to the fact that the Mohammedan wherever he went turned his attention to water, and that was quite true; he had found the same irrigation terms in use in the south of Spain as he knew in the north of India. He thought, however, he was right in saying that the engineering problems placed before the Mohammedan Emperor in Northern India were too great for him, because in the canals which he dug from the Ravi and the Jumna the slope of the country was so great that they became ravines, and they had to be given up. The British Government he thought, therefore, might fairly claim to be the author of those canals. The Punjab was the finest field possible for the use of such canals, and it was impossible to expect that a field equal to it would be found in any other province of India. Irrigation works established in Bombay and Madras must be much more costly, and the results must be much smaller than those in the Punjab. One of the speakers had made a most truthful remark when he stated how much depended upon the sympathy of the

canal and revenue officers. When he first went to Egypt he was fortunate enough to get a most valuable party of officers to follow him from India. They were just beginning to speak Arabic after a year's residence in the country, when complaints began to reach him of oppression in the Irrigation Department, and he told the natives that he would send a native commissioner to inquire into them. They instantly replied, "No, no, for goodness sake do not send him; send one of the new Englishmen." He remembered that on one occasion one of his "new Englishmen," a very brilliant fellow, was riding through a village and was greeted by the not uncommon cry, "There goes a Christian dog," when one of the natives, who knew of his work in the Irrigation Department, said, "No, that man is not a Christian, he is an Englishman." He believed it was that sympathy, apart from his high technical skill, which made the irrigation officer a success. In India they soon found out the difference between the man who looked on his work as an end, and on the man who looked upon the work as a means to an end; and it was the latter kind of man that they always tried to select for the charge of the running water, and for settling the little disputes between man and man.

Mr. T. W. HOLDERNESS, C.S.I., desired, in the first place, to refer to the paradox that the colonists who had been benefited so largely by the canals appeared to be discontented, and, as he gathered from some of the speakers, they were under the impression that the cause of the discontent was the enhancement of the land and water rates. So far as he had studied the question, he thought that was not at all the case. The cause of the discontent was the Colonisation Bill, which the Viceroy had now withdrawn, That Bill did not contain a single clause which had any reference to taxation; it was a Bill for settling certain administrative questions in the colony, regulating successions, imposing sanitary obligations and other things, and to a certain extent it did have restrictive effects with regard to the conditions of the grants. As far as he could make out, the Bill in many respects had been misunderstood by the colonists, and its effect very much exaggerated, and he had no doubt that after a calm season of reflection the people would understand that their fears were unfounded, and would see the necessity for some moderate measure of the kind. The second observation he desired to make was with regard to the continued fertility of the lands. The produce had been very great because water had been applied to virgin soil; but he believed there were signs that the produce was now gradually falling off, and it was a question whether the present great prosperity would continue. That was one of the great problems before the Agricultural Department of India; it was very essential that they should continue to make a very careful study of it, and, if possible, to check both waste of water and exhausting cultivation without manure.

Mr. T. H. THORNTON, C.S.I., D.C.L., said that, having been for many years connected with the Punjab Administration, he desired to ask whether any provision had been made in the Punjab colonies for the systematic planting and conservation of trees. In the first place, trees were very valuable for supplying agricultural implements; and, secondly, it had been found by experience in other parts of the Punjab that belts of trees round villages were very useful in checking the spread of disease. It was quite possible that that work had been done in the Punjab, but no mention was made of it by the author. He desired also to ask whether it had been ascertained that the founding of the villages had led to a great increase of malaria, and if so whether any special measures had been taken for checking its progress.

Mr. ROBERTSON, in reply, thanked the audience very much for the kind manner in which his paper had been received, and the speakers for the kind way in which they had commented on it. Mr. Holderness had shown that the so-called unrest in the Chenab colony was connected, not so much with the taxation of the landholders, as with an agitation which had been got up against a Colonisation Bill. He (Mr. Robertson) thought that burden of proof was on the man who asserted that the taxation of the colonies had been excessive, because the facts were against him, such, for instance as, the prosperity of the people, and that for every acre offered there were thousands of applicants, who were willing to pay the present taxation. In reply to Mr. Thornton, he would like to say that, from the very first, the colonisation officers everywhere had encouraged the planting of trees; and one of the provisions of the Bill to which Mr. Holderness had referred would make it incumbent upon each grantee to plant a certain number of trees throughout the country. He had never heard any scientific explanation of the fact that, when ground unploughed for centuries came into cultivation with the aid of irrigation, the cultivators themselves were certain to get malaria, but in a year or two the virulence of the disease seemed to pass off. The Government did everything to mitigate the evil, by such measures as making available to the very poorest quinine in large quantities at every post office in India. With reference to Mr. Beresford's remarks on the subject of the co-operation of the Irrigation Department, he had no wish whatever in his paper to leave the impression that every man connected with the colonies did not fully appreciate the work which had been done by the engineers, not only in the construction of the canals, but in the distribution of the water and in assisting in every way the cultivators to prosper; indeed, without the engineer there would have been no colonisation officer. The engineer was the first on the ground, and it was only with his co-operation that the colonisation officer could make any progress at all.

The CHAIRMAN, in proposing a very cordial vote of thanks to the author for the paper he had read, remarked that personally he felt very much indebted to Mr. Robertson for the information he had given upon a most interesting subject, while the discussion which had taken place had not been the least important part of the day's proceedings.

The resolution of thanks was put and carried unanimously.

SIR THOMAS HIGHAM, K.C.I.E., M.Inst.C.E., writes:—

Mr. Robertson's paper gives a very interesting account of a very interesting subject, and by a happy thought the writer has placed side by side the leading features in three distinct colonising operations, one of which was carried out at a great distance from the other two, and under a different Administration. It may be noted, however, that the earliest irrigation colonies were not those established on the Chenab. In 1886 colonisation operations were started in the Multan and Montgomery districts in connection with the settlement of about 206,000 and 91,000 acres of waste lands to which irrigation was to be extended from the Sidhnai and the Lower Sohag and Para canals, then under construction in these districts. The operations were carried out by the Deputy Commissioners of the two districts, working on lines which had been laid down by the Financial Commissioner, the late Colonel Wace, who took the strongest personal interest in the matter, and from the first realised the immense importance of these pioneer experiments as a guide for the conduct of the future settlement of the millions of acres of Crown waste on the Chenab and elsewhere, to which the extension of irrigation was known to be feasible, and was then under serious consideration. The plan of operations subsequently adopted on the Chenab was based on the same general lines, but there were, of course, several important modifications in details. Of these it is sufficient to mention the reduction in the size of the peasant allotments. The "unit square" was the same on the Lower Sohag and Chenab canals, 27·7 acres, the side of each square being 1,100 feet, but on the former the peasant generally received 4 squares, or about 111 acres, whereas on the latter he received but a single square. On the Sidhnai, owing to a difference in the local measures, a somewhat smaller unit was adopted, and the average area of the holdings was about 80 acres. These were found in practice to be much too large, and it was decided to limit the peasant allotments on the Chenab to a single square. The much smaller unit subsequently adopted on the Jamrao suggests that the Chenab and Jhelum units are not too small, although many circumstances must affect the comparison. The Sidhnai and Lower Sohag were the first sanctioned projects which involved the extension of irrigation into uninhabited waste lands, even on a modest scale. Up to 1889 the objection had been urged against all large schemes for the irrigation of desert and uninhabited tracts that the development of irrigation would necessarily be so slow that more than a generation must elapse before the net revenue would suffice to meet even the interest charges. There was some foundation for this view in the slow rate of development on existing canals constructed in well populated tracts. The first tentative efforts in colonization on the Sidhnai and Lower Sohag were, however, encouraging, and the subsequent success attained on the Chenab, Jhelum, and Jamrao has clearly demonstrated that as soon as the engineers can deliver a regular supply of water on good cultivable soil there is not likely to be any difficulty in at once attracting as many cultivators as required, if colonization operations are undertaken on the lines which have now been approved by this extended experience. The development of irrigation has indeed been much more rapid in the new colonies than it has ever been in old and established villages on the older canals, or in those on the Chenab Canal itself. The reason is not far to seek. The old proprietors cannot as a class readily adopt themselves to new conditions: they are wanting in enterprise and generally destitute of capital, and are unable or unwilling to offer sufficiently attractive terms to cultivators; whereas in the new colonies every cultivator has a holding of his own, and has the strongest inducement to exert himself to the utmost in the development of his grant.

From an economical point of view the most interesting feature in the leases is the condition in the peasants', and latterly in the yeomen's grants, that the permanent and hereditable right of occupancy in the holding is unalienable either by gift, sale, will, or mortgage. One would like to know how this important provision has worked in practice; whether it is open to all the objections of the *laissez faire* order which were at one time urged against it, or whether it seems likely to secure all the objects which were aimed at when it was introduced. It is perhaps too early for a confident opinion on the results of this new departure, but some of the Chenab leases have been running for fourteen years, or more, and it would be interesting to know whether the experience so far gained of the effect of this provision has been favourable or the reverse.

The railway branches referred to in the paper must have been an indispensable factor of the success attained. In 1894 it was realised that the Chenab colonies would be a failure if a railway were not immediately provided. The 200 miles required formed no part of the current railway programme, but fortunately the Government of India recognised the urgency, and the northern half of the line was opened in the following year. Its success was immediate and surpassed all expectations. Not only was the stability of the colonies assured, but also the line became, as soon as completed, one of the most remunerative sections of the North-Western Railway. After this experience there was no hesi-

tation or delay in constructing the branches subsequently required for the Jhelum tract. Light feeder railways would also be of great service. I agree with the writer that they are likely to prove very remunerative, and when once a start has been made there can be little doubt that many miles of such lines will be speedily brought into operation.

STATISTICS OF NEW ZEALAND FOR 1905.*

Population.—The total estimated population (exclusive of Maoris, &c.) on December 31st, 1905, consisted of 882,462 persons, being an increase during the year of 24,923, made up of 15,621 excess of births over deaths, and 9,302 excess of immigrants over emigrants. Of the total population, exclusive of Maoris, 496,847 are males and 441,050 females.

Vital Statistics.—Several pages are devoted to returns as to the number of marriages, deaths at various ages, cause of death (it may be mentioned that the deaths from phthisis, which numbered 496, were the lowest during the decade), occupations and age at death of males, mental hospitals, benevolent and orphan asylums, as well as industrial schools. Meteorological information under 46 headings is reported for each month of the year from 12 stations.

Shipping.—The returns under this heading cover the number, tonnage, crews, cargoes, and inwards and outwards from each port, with the country of origin or destination. Out of a total tonnage of 1,139,410 entered, 462,850 tons were British owned, 500,467 tons owned by other colonies, and 176,092 foreign owned. The number of New Zealand vessels upon the register is 609, having a gross tonnage of 171,753, and a net tonnage of 119,119 tons.

Imports.—Upwards of 95 pages are devoted to itemized details of the import trade, setting out for each item the total quantitity imported, rate of duty per unit, value of total imports, together with amounts of duty under preferential or general tariff rates. Obviously only a few important items can be mentioned. At the outset one notices the ready-made clothing trade in apparel and slops, aggregating £613,600 in value, and subject to a general tariff duty of 25 per cent. Of this trade £565,588 comes from the United Kingdom. Books enter duty free; the total value was £183,600, of which £136,224 came from the United Kingdom. Boots and shoes pay 22½ per cent. *ad valorem* under the general tariff, with an additional 11¼ per cent. *ad valorem* under the preferential tariff.† The total value imported was £263,523, of which £174,006 came from the United Kingdom, under the general tariff, and £5,313 under the additional preferential rate. Coal, which is duty free, came mainly from New South Wales, which sent 168,757 tons, valued at £155,475, out of the total importation of £169,046 tons. Drapery, subject to a 20 per cent. *ad valorem* duty, amounted in value to £274,020, of which £259,527 came from the United Kingdom. Hardware, hollow ware, and ironmongery, amounted in value to £259,830, of which £195,388 came from the United Kingdom, under the general tariff. Bar, bolt, and rod iron was valued at £129,166; the United Kingdom supplied £123,189 under the general tariff. This proportion is not quite so good in regard to pipes and fittings, of which £99,892 were imported, and rails, total value £102,672, but about 87 per cent. of these articles are British made. The galvanized iron trade is entirely British, £223,074 coming from the United Kingdom, out of £223,135 value imported.

In regard to agricultural machinery, which is duty free, the United Kingdom only supplied £26,055 out of £100,423, the United States supplying £53,479 worth. Electric machinery for general purchasers was imported to a value of £115,557: of this £54,352 came from the United Kingdom, and £46,311 from the United States. There was also imported for Government use electric machinery valued at £42,865, of which £35,776 came from the United Kingdom. There was a good demand for gas and oil engines, the total value amounting to £68,130, of which £40,619 value was British made. Mining machinery, which was duty free, amounted in value to £36,919, of which £29,806 came from the United Kingdom. Woollen piece goods were valued at £406,546, of which £381,071 value came from the United Kingdom. There is no additional tariff upon woollen piece goods made outside the Empire.

The total value of the imports of New Zealand during 1905 was £12,828,857, of which only £599,764 was subject to extra preferential duties. The total nett duty received therefore under the Customs tariff was £2,652,666, of which £64,377 represented sums collected in the shape of extra duties.

Exports.—The figures relating to specific items of export trade describe whether made within or without the colony, and values in each case. The total values of the exports to New Zealand during 1905 amounted to £15,655,947, of which £15,503,530 represents the produce and manufactures of the colony. Of this total no less than £12,087,818 went to the United Kingdom, while France received £48,963, Germany £38,958, and the United States £716,301. The Australian Commonwealth received exports valued at £2,268,373. As regards the component items of export trade, the following figures are of interest:—Gold, £2,098,936; timber, £891,410; butter, £1,408,557; meat (frozen), £2,694,432; wool, £5,381,333; wheat, £144,374; and leather manufactures, £696,467.

Wages.—The average rates of wages are set out for nine districts for several occupations. Space only permits a few quotations, extreme ranges being

* Abstracted from the official returns, compiled in the Registrar-General's Office, and printed by John Mackay, Government Printer, Wellington, 1906. Two vols., 652 pp.

† It should be noted that under the New Zealand Preferential and Reciprocal Trade Act of 1903, certain articles *not* being the produce or manufacture of some part of the British Dominions, become subject to additional taxation.

given:—Farm labourers, without board, 5s. to 8s. per day, with board, 17s. 6d. to 25s. per week; shepherds, with board, per annum, £52 to £80; masons, per day, without board, 10s. to 14s.; bricklayers, per day, without board, 10s. to 14s.; smiths, per day, without board, 8s. 6d. to 12s.; cooks, with board, per week, 15s. to 30s.; general servants, with board, per week, 10s. to 17s. 6d.; general labourers, without board, per day, 7s. to 10s.; shop assistants, without board, per week, 30s. to 60s.

Railways.—The total mileage of line open for traffic on March 31st, 1906, was 2,407. The cost up to that date was £22,498,972. The gross revenue was £2,349,704. Working expenditure absorbed 69 per cent. of the receipts, leaving a net revenue of £728,465, which is equal to £3 4s. 9d. per cent. of earned interest.

Production.—The pages relating to production cover such items as increase of live stock, numbers of flock owners, acreage of crops, numbers of factories (with details as to number of workpeople, value of materials produced, and value of site, buildings, machinery, and plant). So far as factories are concerned, these returns relate only to the industrial census of 1900.

As regards the total live stock, the following are the figures for 1905-6: horses, 326,537; cattle, 1,810,936; sheep, 19,130,875; and pigs, 249,727.

The coal raised within the colony was 1,585,756 tons, being an increase of 47,918 tons over the preceding year. The total value of the gold and silver produced was £2,224,478, of which the silver was valued at as £120,542. The total number employed in the gold mines in 1905 was 9,362, of whom 803 were Chinese occupied in alluvial work.

Education.—A return giving the ages of scholars attending public schools shows that out of a total of 137,623 scholars only 2,586 are over 15 years of age; of other ages there are between 14 and 15, 5,414, between 13 and 14, 11,423; between 12 and 13, 14,579; and between 11 and 12, 15,453. The subjects of instruction in the primary sechools embrace English, arithmetic, drawing, singing, physical instruction, geography, history, nature study and elementary science, handiwork and needlework. Figures are given of the number of scholars returned as learning each subject. Thus 52,777 out of 65,673 girls receive instruction in needlework. History seems the most neglected study, only 59,956 scholars attending these classes. Geography is more highly regarded, 79,981 being the number reported. Handiwork is taught to 93,565 scholars. All other subjects are taught to 122,000 or more children in these schools. Government grants provide £641,025, and local sources £8,697 for expenditure on these primary schools.

Secondary or superior schools are attended by 2,467 boys and 1,593 girls. The total expenditure on secondary schools in 1905 was £88,191, towards which fees produced £29,575, Government grants, £14,137, and endowments £35,627.

The New Zealand University had upon its rolls on June 1st, 1906, 807 male and 532 female nudergraduates in the faculties of arts, science, law, and music, and 117 male and 32 female undergraduates in the faculty of medicine.

Other educational returns relate to private or denominational schools and schools for Maoris.

Other Statistics.—Such matters as postal and telegraph finances, law and crime, and local government statistics of boroughs, counties, &c., do not call for comment in these pages.

JAPAN AND THE CHINESE COTTON MARKETS.

Persistent efforts are being made by Japanese merchants, with the aid of the Government, to capture the cotton markets of China, and with this object in view, the Japanese mills have, during the last six months, increased the number of their spindles. Evidence is not wanting that the Japanese Government is looking with favour upon, and lending financial assistance to, the development of the cotton industry. Japan has many things in her favour in this struggle for the Chinese cotton market. She has an abundance of cheap, concentrated labour, she understands the wants of the Chinese people, and is in a better position geographically to meet the demand, than any other country. China is producing large quantities of cotton, but the quality is not good, and has to be mixed with either American or Indian cotton to produce good fabrics. Japan uses large quantities of Chinese cotton in the manufacture of textiles, and will no doubt seek control of the supply. She is even now, it is said, growing cotton of her own, in order to make herself independent of the foreign supply. It is interesting in this connection to note the sources from which Japan obtains her raw cotton. From reliable statistics for the half-year ended June 30th, 1906, it is shown that the cotton mills of Japan used 209,574,662 pounds of raw cotton. Of this amount India supplied the greatest quantity, 75,673,683 pounds; China 67,996,954 pounds; and America 58,541,589 pounds. From all other sources only 7,362,436 pounds were used. With three exceptions all the mills in Japan used American cotton. Five mills did not use Indian cotton at all, and five did without any of the Chinese product. The total number of spindles in operation in the cotton mills of Japan last July amounted to 1,371,730, and the cotton consumed that month amounted to 35,814,125 pounds. These figures evidence the rapid strides the cotton industry is making in Japan. Nearly every mill increased its spindles and enlarged its capital stock, and every mill showed a satisfactory financial condition. There has been under consideration the question of building a cotton mill in Dalny, but conditions for several years to come will not warrant the outlay. The cost of living is double what it is in Japan, and there is a scarcity of labour which would make such an institution almost impossible to work at a profit.

HOME INDUSTRIES.

Illegitimate Industries.—A report of the Medical Officer of the Port of Manchester reminds one of what may be called the illegitimate industries that thrive in connection with food imports. The food stuffs brought into the port of Manchester last month were in excellent condition with the exception of a small percentage of grain damaged through contamination with bilge water, or from contact with the moisture condensing on the iron sides of the vessel. This contamination gave rise to fermentation, with the creation of considerable heat, and produced a mass of material upon which moulds and bacteria throve vigorously. Samples of damaged wheat and maize were sent to the Public Health Laboratory for examination, and the result showed that each sample contained moulds. The danger from consumption of these materials is the presence of bacili of the coli type; the unknown dangers cannot be gauged. But this poisonous stuff has a ready sale. It is used for the feeding of pigs, and the making up of poultry food, and is also used in the manufacture of articles intended for human consumption, especially cheap whisky and glucose. Dr. Dearden states in his report that he had made a hard and fast regulation not to deliver such grain to any person except a purchaser who would himself utilise it for purposes other than human food, and then only on an undertaking to allow an inspector of the Authority to visit the place of utilisation and satisfy himself as to the genuineness of the guarantee. But it is to be feared that medical officers are not always so alive to their responsibilities, and that despite all the precautions taken much poisonous stuff is used in the preparation of human foods. Between April 29 and May 26 the amount of food stuffs condemned at the foreign animals wharf, Manchester, and the docks, weighed 14 tons 16 cwt. 1 quarter 27½ lb., and included wheat which was delivered to the owners for making poultry food and cornflour, and which was allowed to go for the purpose of "size" making. It appears that the Authority has at present no legal power to prohibit the sale of foodstuffs which are not intended directly for human consumption. If the inspecting officer is satisfied that the unsound wheat is not to be used directly as human food he cannot prevent its leaving the docks to be used for, say, poultry feeding. The law would seem to need strengthening in this respect, and the public health to require that foodstuffs in a rotten condition when they reach British ports shall be destroyed forthwith.

The Cotton Position.—The report of the American Census Bureau upon the cotton crop confirms the general impression as to the present outlook. The estimate of condition is 70·5 as against 84·6 last year. The necessity for replanting has made the crop a late one. A great amount of seed was killed by the cold, wet weather, and the planters have had difficulty in replacing it; those who had planted "bender" seed have now had to be satisfied with seed of a poor grade; and a good deal of the seed used has been found infertile. As to acreage, the estimate is 36,060,000 against 28,686,000 last year, but last year's estimate was not generally accepted. Last month was the smallest turnover in piece goods in the cotton trade in Lancashire for some years. There has been no stimulating influence from abroad to encourage exporters to operate. Cotton continues high, and yarn remains dear. Meantime cotton mill construction proceeds, notwithstanding the increased cost of machinery, understood to be close upon 20 per cent. dearer than eighteen months ago. A new spinning mill is about to be erected at Bolton, another at Chorley, and two at Oldham, in all 450,000 spindles, costing £600,000. And some of the new concerns that have been working only six months or so are about to erect No. 2 mills.

The Coal Trade.—Now that many of the annual coal contracts have been arranged, the extent of the advance which has been made by the coal trade of the country during the year may, to some extent, be gauged. An average increase of 3s. per ton has been established in gas coal for contracts over the next twelve months. Steam coal shows an even higher advance, best large Welsh coal being fully 4s. dearer than a year ago, whilst the renewal of London house coal contracts is based on an advance of 2s. 6d. per ton. Except house coals, the heavy demand for fuel which set in last autumn continues. Orders from abroad are coming in at a record rate, and it is estimated that the exports of coal from the United Kingdom for the first six months of 1907 will show an increase of not far from three million tons as compared with those for the corresponding period of 1906.

Life Insurance without Examination. — Many persons willing and even anxious to insure their lives object to the medical examination, which until lately was indispensable, and remains with most offices a condition of insurance, but one well-known and enterprising life office has for some time past consented, upon conditions, to waive the medical examination. The result has been considerable additional business, and the managers of the institution are well satisfied with the experiment. The conditions under which insurance without examination are effected are as follows:—Insurance is not effected after the age is over 50, or for less than £100, but with these limitations the company will entertain proposals under whole life and endowment assurance tables at the ordinary rates of premium, subject to being satisfied from the statements made by the proposers that their lives are not ineligible on account of family or personal history. If the life assured die during the first year following the date of assurance, the amount payable will be one-third of the sum assured, if he die during the second year two-thirds of the sum assured, and

on a claim occurring at any time after two years from the date of assurance, the full sum assured will be payable. In the event of the life assured's death from accident at any time, the full sum assured will be payable. No assignment of a policy is allowed until the expiration of two years from the date of assurance.

Dairy Farming.—A writer in the *Times* combats the general opinion that British farmers have much to learn from Denmark, which is so frequently held up as an example to Great Britain, especially in connection with dairy farming. The writer in the *Times* submits figures to show that the British dairy farmer realises twice as much for his milk as does his Danish rival. The latter sells to to the factory at something less than 4d. per gallon, whereas in this country the price for new milk, delivered at the station, ranges from 6d. to 8d. But that only shows that the British farmer has a better market for his milk than the Danish, which is obviously the case, seeing that Great Britain is studded with highly prosperous, industrial towns, whereas in Denmark it is pretty well all country. Admittedly Denmark excels in co-operation, which has never taken much root among English farmers, but the cheaper production of Denmark is largely due to lower wages, and if a larger number of people are maintained on the land in Denmark than in Great Britain the explanation is to be found in the unwillingness of the Dane to emigrate, and the consequent necessity of finding a living upon the land since the opportunities of town life are not as a rule open to him. But whilst a good deal of exaggeration is frequently indulged in when comparison is made between British and Danish farming methods, it may be allowed that in some respects the Danes set an example that British farmers might follow with advantage. For instance, they pay much greater attention to cleanliness and to proper packing. Even now cows and pigs upon English farms are often kept in a filthy condition, methods of milking and the transport of milk leave much to be desired; and the benefits of co-operation, which are so marked in Denmark, are very imperfectly appreciated in Great Britain though, strangely enough, much greater progress in this direction has of late years been noticeable in Ireland.

The Hematite Iron Trade.—The hematite iron trade continues to be remarkably prosperous. The exports to America and the continent show large increases and there is a strong demand for early deliveries of the metal. During the first week of June 10,922 tons of iron, and 14,002 tons of steel were exported as compared with a total in the two classes last year of 8,732 tons, an increase of 16,192 tons. The total shipments this year are 409,833 tons as compared with 324,596 tons last year, an increase of 85,237 tons. Warrant stocks show renewed reduction, which must further strengthen the market. They stand at 30,793 tons, or less than a week's output of the furnaces of the district. Additional furnaces are to be put in blast to cope with the demand, for makers still hold large orders for delivery to the United States and the Continent, and local steel makers are also requiring larger deliveries. It looks as if the present year will be a record one in the north-west of England hematite iron trade.

Colonial Wool.—The figures of the wool exports from Australasia are remarkable. They cover the eleven months to the end of May, and show an increase of 230,000 bales as compared with the corresponding period of last year. The increase from Australia alone is 216,000 bales. When the drought ended in 1902 the exports had fallen below 1,000,000 bales. The previous highest record was not quite 1,600,000 bales. For the eleven months to May the exports were 1,629,000, so that with another month of the year to run they exceed those of any previous year by 30,000 bales, and are 640,000 bales more than they were in the years 1902-3. The increase for 1907 8 promises again to be very large. The arrivals of Colonial wool in this country up to last week since the closing of the list for the late auctions in London was 213,000 bales, of which 112,500 bales were forwarded direct to consumers here and on the Continent. The methods adopted by growers of Colonial wool for the realisation of their clips have been greatly changed in recent years. Formerly nearly everything was sent to London for sale, but now the clip, in large part, changes hands in Australian markets. How serious is the competition of Colonial with London brokers will be understood, says the *Manchester Guardian*, when it is remembered that during the present wool year, which will come to an end on the 30th inst., more than three-fourths, and probably not less than seven-eighths of the entire Australian clip, amounting to 1,700,000 bales, will have changed hands in Australia. The "epidemic," as London brokers and warehousemen call it, is extending every year, and it now looks as if the proportion of direct purchases in New Zealand, Tasmania, and South Africa will, in a few years, be quite as large as the Australian. Naturally, the London brokers are unwilling to lose their business without a struggle, and circulars are issued by some of them from time to time to prove that London is the best market in which growers can realise their wool. Australian newspapers, on the other hand, urge that no sensible pastoralist can be so blind to his own interests as to ship his wool to London instead of selling in the Colonial markets. All Australians are unanimous as to that, the divergence shows itself when the comparative merits of the various markets in the Commonwealth are considered. Melbourne, Sydney, Brisbane, Adelaide, are struggling for the business that not so long ago was transacted almost exclusively in London.

GENERAL NOTES.

THE SS. "ADRIATIC."—On May 8th there sailed from the Mersey a vessel larger than any that had hitherto crossed the Atlantic. The *Adriatic* cannot be described as the largest ship afloat, for the new Cunarders—the *Mauretania* and *Lusitania*—although they are not yet completed ready for service, considerably exceed even the *Adriatic* in dimensions and tonnage. The construction of the huge White Star liner has been somewhat thrown into the shade by the building of the two great ships of the rival company. Although not comparable with these latter in many respects, and, of course, intended for a different class of trade, the sailing of the *Adriatic* is a noteworthy event. Just thirty-five years ago the great Belfast shipyard of Harland and Wolff built another *Adriatic*—a ship famous in her day, and one of the finest vessels afloat at that time. She was 449 ft. 6 in. in length, 40 ft. 9 in. beam, and her gross tonnage was 3,887. The new *Adriatic* forms a striking contrast with her predecessor. Her length is 725 ft. 9 in.; breadth, 75 ft. 6 in.; depth, 50 tt.; and her gross tonnage, 25,900. The displacement is over 40,000 tons. She will carry 3,000 passengers in addition to the crew. The *Adriatic*, although making her maiden voyage from Liverpool, will henceforth use Southampton as headquarters, and arrived at that port on her return journey on May 30th, leaving again for New York on Wednesday last, thus commencing the regular weekly express service of the White Star Company between Southampton and New York. It is fourteen years since the American line adopted Southampton as its headquarters on this side of the Atlantic, since when the development of the port has been continuous and rapid, culminating this year in the transfer of the four White Star boats and the establishment of a branch yard at Southampton by Messrs. Harland and Wolff, work in connection with which is already in hand. It is stated that the Southampton Dock Board has decided to carry out the additional dredging rendered necessary for the accommodation of the new White Star vessels at its own cost, and not to depend on aid from the London and South-Western Railway Company to effect this, as was at first proposed, otherwise than by taking advantage of a loan from the company. The estimated cost is £50,000.—*The Engineer*.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JUNE 17...Geographical, University of London, Burlington-gardens, W., 8½ p.m. Major P. H. G. Powell-Cotton, "In the Equatorial Forests of Africa."

TUESDAY, JUNE 18...Asiatic, 22, Albemarle-street, W., 4 p.m. Mr. James Kennedy, "The Child Krishna, Christianity and the Gujars."

Statistical, 9, Adelphi-terrace, W.C. 4½ p.m. Annual General Meeting. 5 p.m. Mr. W. G. S. Adams, "Some Considerations relating to the Position of the Small Holding in the United Kingdom."

Zoological, 3, Hanover-square, W., 8½ p.m.

WEDNESDAY, JUNE 19...Meteorological, 70, Victoria-street, S.W., 4½ p.m. 1. Mr. Francis Campbell Bayard, "Weather and Crops, 1891-1906." 2. Mr. Charles P. Hooker, "The Relation of the Rainfall to the Depth of Water in a Well at Cirencesier, 1903-1906."

Geological, Burlington-house, W., 8 p.m.

Microscopical, 20, Hanover-square, W., 8 p.m. 1. Mr. E. M Nelson, "Eye-pieces for the Microscope." 2. Mr. F. Enock, "Life-history of the Tiger Beetle, *Cicindela campestris*."

British Archæological Association, 32, Sackville-street, W., 8 p.m.

THURSDAY, JUNE 20...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Dr. Maxwell T. Masters, "Distribution of Conifers of China." 2. Mr. Clement Reid and Mrs. Reid, "Pro-glacial Flora of Great Britain." 3. Dr. J. Stanley Gardiner, "Cruise of H.M.S. *Sealark*." Part II. 4. Mr. A. W. Waters, "*Tubucellaria*." 5. Dr. N. Wolfenden, "Cruise of the *Silver Belle*." 6. Mr. E. A. N. Arber, "Triassic species of *Zanisko* and *Plerophyllum*."

Chemical, Burlington-house, W., 8½ p.m. 1. Mr. A. T. Cameron and Sir W. Ramsay, "Some Properties of Radium Emanation." 2. Mr. V. H. Veley, "The Affinity Constants of Aminosulphonic Acids as determined by the aid of Methyl Orange." 3. Mr. M. A. Whiteley, "Azo-derivatives of 1 : 3-diphenylbarbituric Acid; Dynamic Isomerism amongt he coloured Hydrazones of 1 : 3-diphenylalloxan." 4. Messrs. G. T. Morgan and W. O. Wootton, "A series of coloured Diazo-salts derived from p-amino-aceto-α-naphthalide." 5. Messrs. J. T. Hewitt and H. V. Mitchell, "Colour and Constitution of Azo-compounds." Part I. and II. 6. Mr. F. D. Chattaway, "The Oxidation of Hydrazines by Free Oxygen." 7. Mr. F. L. Pyman, "Calmatambin: a new Glucoside." 8. Messrs. P. C. Ray and A. C. Ganguli, "The Decomposition of Hyponitrous Acid in presence of Mineral Acids." 9. Messrs. H. O. Jones and H. A. Wootton, "The Chemical Composition of Petroleum from Borneo." 10. Messrs. A. Senier and C. Austin, *a.* "The Synthesis of Phenonaphthacridines. Trimethylphenonaphthacridines." *b.* "The Condensation of Aldehydes with Mixtures of α-Napthol and α-Napthylamine: Synthesis of 7-Aryl $\begin{array}{c}\alpha\text{-N-}\alpha\\ /\\ \beta\text{-CH-}\beta\end{array}$ Dinaphthacridines. 11. Messrs. W. R. Lang and T. B. Allen, *a.* "An Improved form of Apparatus for the Rapid Estimation of Sulphates and Salts of Barium." *b.* "The Determination of Sugar by Fehling's Solution."

Optical, 20, Hanover-square, W., 8 p.m. Mr. W. A. Dixey, "A New Instrument to Measure the Fusion Power of the Eyes." 2. Discussion on "The Influence of Position of the Object on the Effective Value of High Power Sphero-cylindrical Lenses." Introduced by Mr. S. D. Chalmers.

Numismatic, 22, Albemarle-street, W., 6½ p.m. Annual meeting.

FRIDAY, JUNE 21...Art Workers' Guild, Clifford's-inn-hall, Fleet-street, E.C., 8 p.m. Paper on "Methods of Painting."

Historical, Lecture-hall, Field-court, Gray's-inn, W.C., 5 p.m.

Quekett Microscopical Club, 20, Hanover-square, W., 8 p.m.

Journal of the Society of Arts.

No. 2,848. VOL. LV.

FRIDAY, JUNE 21, 1907.

FINANCIAL STATEMENT.

The following statement is published in this week's *Journal* in accordance with Sec. 40 of the Society's By-laws —

TREASURERS' STATEMENT OF RECEIPTS AND PAYMENTS FOR THE YEAR ENDING MAY 31ST, 1907

Society's House, Adelphi, 20th June, 1907.

NOTICES.

ANNUAL GENERAL MEETING.

The Council hereby give notice that the One Hundred and Fifty-third Annual General Meeting for the purpose of receiving the Council's Report and the Treasurers' Statement of receipts, payments, and expenditure during the past year, and also for the election of officers and new members, will be held in accordance with the By-laws on Wednesday, 26th June, at 4 p.m.

(By Order of the Council),
HENRY TRUEMAN WOOD,
Secretary.

CONVERSAZIONE.

The Society's Conversazione will be held, by arrangement with the Council of the Royal Botanic Society, in the gardens of that Society, Inner Circle, Regent's-park, on Tuesday evening, July 9th, from 9 to 12 p.m.

The central portion of the gardens only will be used. The Conservatory and the Club house will be open.

The reception, by Sir Steuart Colvin Bayley, K.C.S.I., C.I.E., Chairman, and the other members of the Council, will be held at the entrance to the Conservatory, near the Broad-walk, from 9 to 10 p.m.

The Tropical-house, containing the Giant Water Lily (Victoria Regia), and other interesting tropical plants, will be open to visitors, and will be specially illuminated for the occasion.

An Exhibition of Growing and Cut Roses and other Flowers will be arranged in a marquee in the grounds by Messrs. W. Paul and Sons, of Waltham-cross.

A Selection of Music will be performed by the String Band of the Royal Marine Light Infantry (Portsmouth Division) in the Conservatory, and by the Band of H.M. Coldstream Guards in the Gardens, commencing at 9 o'clock.

A "Watteau" Pastoral Play in three acts, entitled "La Marquise," will be performed in the Gardens by Mr. Patrick Kirwan's Idyllic Players, commencing at 9.30 p.m.

A Concert and Entertainment, under the direction of Mr. Patrick Kirwan, will be given in the Club-house at 9.45 and 10.45 p.m.

Each member is entitled to a card for himself (which will not be transferable) and a

card for a lady. These tickets will be issued next week. In addition to this, a limited number of tickets will be sold to members of the Society, or to persons introduced by a member, at the price of 5s. each, if purchased before the day of the conversazione. On that date the price will be raised to 7s. 6d.

Members can purchase these additional tickets by personal application, or by letter addressed to the Secretary at the offices of the Society, John-street, Adelphi, W.C. In all cases of application by letter a remittance must be enclosed. Each ticket will admit one person, either lady or gentleman, and must be signed by the member applying for it.

Tickets will only be supplied to non-members of the Society on presentation of a letter of introduction from a member.

Further particulars as to the musical and other arrangements will be given in the Programmes, which will be distributed on the evening.

PRIZE FOR LIFE-SAVING APPARATUS FOR USE IN NOXIOUS ATMOSPHERES.

The Council of the Society of Arts are prepared to award, under the Fothergill Trust, a Gold Medal, or a prize of £20, for the best portable apparatus or appliance for enabling men to undertake rescue work in mines or other places where the air is noxious.

It is intended that the apparatus sent in shall be submitted to practical trials and tests.

In the award of the Medal regard will be had, firstly, to excellence of design and contrivance, and, secondly, to excellence of manufacture. Credit will be given to such parts of the apparatus as are the invention of the exhibitor; the object being to distinguish the apparatus which gives the best promise of being practically useful.

Inventors intending to compete should send in a notice of their intention, together with a full description of their inventions, not later than 31st March, 1908, to the Secretary of the Society of Arts, John-street, Adelphi, London, W.C.; and in cases in which the apparatus has been put into actual use, the experience of such use should be given, and the special points of merit of the apparatus indicated.

Notice of the place to which the apparatus is to be sent will be subsequently given to those competitors whose apparatus the judges may desire to test, together with an indication of the tests, and of the manner in which they will be conducted.

Competitors intending to patent their inventions should be careful to obtain protection, as the Council of the Society cannot undertake any responsibility as regards the secrecy of the whole, or of any part, of an invention submitted to them.

The Prize will be awarded on the report of judges appointed by the Council.

The competition is not limited to British subjects.

The Council reserve to themselves the right of withholding the Prize, of extending the time for sending in, or of awarding a smaller Prize or smaller Prizes.

COMMITTEE ON THE DETERIORATION OF PAPER.

A meeting of the above committee was held on Wednesday, the 12th instant, at 4 p.m. Present:—Sir Steuart Colvin Bayley, K.C.S.I., C.I.E. (in the chair), Clayton Beadle, W. C. Knight Clowes, M.A., Charles G. Cresswell, C. F. Cross, F.C.S., Cyril Davenport, Hugo Müller, Ph.D., F.R.S., Sir Boverton Redwood, D.Sc., F.R.S.E., William J. Russell, Ph.D., F.R.S., Carmichael Thomas, Prof. J. Millar Thomson, F.R.S., Dr. Quirin Wirtz, M.A., F.I.C., and Sir Henry Trueman Wood (Secretary).

EXHIBITIONS IN GREAT BRITAIN AND IRELAND SINCE 1890.*

By the Secretary of the Society.

Since the publication in the Society's *Journal* of November 8th, 1889, of the Memorandum on Exhibitions held in Great Britain and Ireland, which was prepared at the request of the Secretary of State for Foreign Affairs for the use of the Committee then occupied in organising the exhibition at Chicago, there have not been many exhibitions held in this country of an important character, or properly entitled to the epithet International.

The largest and most successful was that held in Glasgow in 1901. This resulted in a surplus of over £30,000. One held in the following year at Wolverhampton was less successful, as it resulted in a deficit of about £34,000. This was on a smaller scale than Glasgow. A still smaller exhibition was held at Bradford in the year 1904, which left a

* Supplementary to a Memorandum on British Exhibitions issued in 1889. (*See* vol. 37, p. 900.) Prepared at the request of the Board of Trade for the information of the Japanese Government.

surplus of nearly £15,000. A successful exhibition was also held at Cork in 1902, but the surplus of over £6,000 was due to the liberality of the subscribers, without whose assistance the exhibition would not have paid its expenses. In 1896 one was held at Cardiff; it had a small balance on the wrong side. Many smaller exhibitions were held at some of the chief centres of industry, Manchester, Liverpool, Bristol, Birmingham, &c. Some of these were of the nature of private speculations, others were promoted by local committees. Most of them may be said to have been popular and successful. In many cases they were certainly profitable to their promoters and beneficial to the local industries.

In London no large exhibitions have been held, though there have been a great number of various characters, particulars of some of which are given a little later on. It is certainly the fact, as far as this country is concerned, that the tendency of late years has been towards exhibitions of a special character dealing with particular trades or industries. These are of necessity small as compared with the large International Exhibitions of the past; but they seem on the whole to be regarded as more useful for business purposes by manufacturers and traders than such large exhibitions. They do not necessarily appeal specially to the general public, but they offer useful opportunities for the transaction of business, and, judging from their success, such opportunities are much appreciated and generally utilised.

It must not be forgotten that exhibitions on the scale of Paris, Chicago, or St. Louis, can only be carried on at a very heavy loss, which loss has to be made good by subscriptions or grants from one source or another. The receipts from the admission of visitors, and from the various payments made by those visitors, a large proportion of which of necessity reaches the exhibition coffers, can never be sufficient during the season for which an exhibition is open to meet the very heavy charges for buildings, installation, &c., when these are on the large scale and of the elaborate character induced by international rivalry. It may be worth while for a country or a city to incur this loss in view of the indirect benefits gained, but it must be regarded as most probable that in the future the occasions on which such indirect benefits will counterbalance the certain loss will be few and far between, though they are quite likely at intervals to recur. It is probable that in the case of Paris the indirect profits to that great city are sufficient to induce the Government to keep up the series of Paris Exhibitions, and it would be a matter for regret if the series were not continued, but it is difficult to name any other city which would gain in the same way. A new and rising country, anxious to develop its industries, might be inclined to face the cost of advertising them by an exhibition on the international scale, but so far as careful consideration of the conditions may justify prophecy, it seems unlikely that in the immediate future any of the older countries will be willing to meet the necessary expenditure. It, therefore, seems reasonable to expect that in the future we shall have a number of smaller exhibitions, of which a considerable proportion will be confined to some special subject or group of subjects, rather than any of the great International Exhibitions of the past.

I.—London Exhibitions.

During the period under consideration there have been in London no important exhibitions of an international character, but it may be useful to put on record some account of the exhibitions which have been held. The two most important exhibitions held in London during the period 1890-1906 were certainly the Royal Military Exhibition at Chelsea in 1890, and the Royal Naval Exhibition at the same place in 1891. Both of these were extremely successful. They were held on ground belonging to the Chelsea Hospital, an area of about 7½ acres. The exhibits were mainly loans, but trade exhibitors were charged 5s. per square foot.

The number of visitors to the Royal Military Exhibition, 1890, was 923,761. The total receipts of this exhibition were a little over £55,000, of which £36,750 came from admissions, and about £9,000 from concessions, sale of space, &c. A little over £6,000 was received from donations. The expenses amounted to over £45,000, of which £18,500 was for buildings, installation, &c. The surplus was nearly £10,000.

The attendances at the Royal Naval Exhibition 1891, were much larger—2,351,683. The total receipts were nearly £155,500, of this admissions accounted for £109,000, and concessions, space, sale of catalogues, &c., for about £46,500. The expenditure amounted to about £108,500; of this £36,000 was for buildings, installation, restoration of grounds, &c., £10,700 for entertainments, £6,500 for

illuminations. There was a balance of £47,000. The profits from these two exhibitions were devoted to certain military and naval benevolent institutions.

As mentioned in the previous memorandum, a series of exhibitions was started at Earl's Court after the last of the South Kensington exhibitions—the Colonial and Indian Exhibition held in 1886. These have been continued since, and have proved very popular, and well attended. They are in the hands of a private company, and are believed to have been profitable, the grounds being a very popular place of resort during the summer,* and providing what is much appreciated in London, a place of out-door recreation under good and careful management. During the same period a number of exhibitions of different characters have been held at the Crystal Palace, Sydenham. These have most of them been of a special character, and though some of them have been termed International, they were none of them genuine International Exhibitions.†

At the Imperial Institute several exhibitions have been held, all of them devoted to some special subject. The first of these was in 1894, and dealt with Pottery; in the next year (1895) the subject was Photography, in 1897 there was a Yachting and Fisheries Exhibition, in 1898 an exhibition of Acetylene Generators, in 1899 an exhibition of Ecclesiastical Art, and in 1900 one of English Education.

In 1899, at the suggestion of the Society of Arts, the Science and Art Department held an exhibition of Lithography to commemorate the invention of lithography by Senefelder in 1798. This was followed by a series of exhibitions of Methods of Illustration: 1901, Illustration by Typographical Methods; 1903, Engraving and Etching; 1905, Photogravure and other Photographic Methods. These were international, and included large and representative collections of foreign work.

A small general Industrial Exhibition was held in the People's Palace, East London, in 1896.

In addition to these were many other smaller exhibitions, and also a number of exhibitions dealing with special subjects, most of which were at the Agricultural Hall, or at Olympia. The more important of these dealt with such subjects as Tramways and Light Railways, Bicycles, Electrical Appliances, Engineering, Motors, Building Materials, Colliery and Mining Plant, Gas, Confectionery, Furniture, Brewers' Products, Groceries and Provisions, Tobacco, Boots and Shoes, &c.

The occasional exhibitions of Arts and Crafts promoted by a committee formed for the purpose should be mentioned, as affording interesting evidence of the character of, and the changes of method in, the artistic industries of the country.

II.—Provincial Exhibitions.

Glasgow.—A second exhibition was held at Glasgow in 1901. This, like the previous exhibition of 1888, attracted a very large number of visitors and was a considerable financial success. The total receipts amounted to £404,105, of which £283,024 was from admissions, £84,122 from refreshment and other concessions, and £34,923 payments for space. The surplus, as estimated in the published balance-sheet, was £30,571. It was expected this would be somewhat increased by the sale of the buildings. The cost of the buildings and grounds was £222,886, £37,936 was paid for music and entertainments, and there was a Women's Section costing £1,314. The general administration expenses were given as £51,574, and the engineer's department £36,890. The total number of admissions was 11,559,649. The admission was one shilling, children half-price, and during a certain portion of the exhibition the entrance after five p.m. was reduced to sixpence.

Bradford.—In the year 1904 an exhibition was held in Bradford to inaugurate the opening of the Cartwright Memorial-hall, which was presented to the city by Lord Lister. This was not entitled an International Exhibition, but there were a few foreign exhibitors. The exhibition was not on a large scale, but it was a distinct financial success. There were in all nearly two million and a-half visitors, but this number appears to have

* The present series commenced in 1895, and include the following:—Empire of India Exhibition, 1895; Empire of India and Ceylon Exhibition, 1896; Victorian Era Exhibition, 1897; International Universal Exhibition, 1898; Greater Britain Exhibition, 1899; Woman's Exhibition, 1900; Military Exhibition, 1901; Paris in London Exhibition, 1902; International Fire Exhibition, 1903; Italian Exhibition, 1904; Naval, Shipping and Fisheries Exhibition, 1905; Imperial Royal Austrian Exhibition, 1906.

† The Secretary of the Crystal Palace has kindly furnished the following list of exhibitions held there since 1890:—Photographic (1890), Mining (1890), Horticultural (1891), Photographic (1891), Electrical (1892), Photographic (1893), Sports and Pastimes (1893), South African (1895), Horse-drawn and Horseless Carriages (1896), "Imperial Victoria Exhibition" (1897), Photographic (1898), "Article Club" (1899), Music (1900), Naval and Military (1901), American (1902), Engineering and Hardware (1903), Music (1903), Food and Grocery (1903), Indian and Colonial (1905), Food, Health and Hygiene (1906), Pianoforte and Music Trades (1906).

included rather more than 40,000 free admissions. The total receipts amounted to £66,114. The expenditure was £51,148, leaving a surplus of £14,966. This surplus was devoted to the expenses of the Cartwright Memorial-hall—£5,000 towards the cost of erection, and £10,000 to the purchase of works of art, and furnishings for the hall. The receipts from admissions were £41,828. The amount received in payments for space was £4,551, the charge to exhibitors being 3s. per square foot. £11,688 was received from the various concessions and entertainments.

Wolverhampton.—In 1902 an International Exhibition was held at Wolverhampton. Financially this was unfortunately very far from successful, as it resulted in a deficit of about £34,000, which had to be met by the guarantors. The total expenditure was about £93,000—buildings £35,174, power and light £9,088, entertainments £13,986, fine arts £2,000, advertisements £5,514. The total receipts were about £59,000—season tickets £9,117, admissions £27,000, sale of space £6,033, concessions £12,056.

Cork.—An International Exhibition was held at Cork in 1902. This resulted in a surplus of £6,179, but it can hardly be said that this was earned by the exhibition inasmuch as donations were received amounting to nearly £16,000. The total receipts were £61,519; the expenditure was £55,340. Besides the amount of donations above mentioned the principal items of receipts included £26,000 admissions, £8,500 sale of space, and various concessions and other receipts £9,500.

The exhibition was re-opened in 1903, and a portion of the surplus was carried forward towards the expenses of the second year. The remainder was applied to the purchase of ground for a park.

Cardiff.—A Fine Art, Industrial, and Maritime Exhibition was held in this City in 1896. The exhibition was held in Cathays-park, the use of which was granted by the late Lord Bute for the purpose. The number of admissions amounted to about a million. The expenditure amounted to £31,000, of which buildings and machinery came to about £15,000, and electric light £3,000. The receipts amounted to rather less than £30,000, the balance of £1,700 being made up by the guarantors. Of the receipts £22,500 was from admissions, and £5,700 from rent of space, concessions, &c.

Dublin.—An International Exhibition is now being organised in Dublin. The arrangements are now (January, 1907) far advanced towards completion, and hold out every promise of success.*

AFRICAN TREE RUBBER.

The *Kew Bulletin* (No. 5, 1907), quotes a letter addressed to the editor of the *Agricultural News*, Barbados (vol. vi., No. 127, p. 77), Mr. H. Hesketh Bell, C.M.G., which supplies an interesting account of the system of tapping indigenous *Funtumia elastica* trees in Uganda, and of the subsequent treatment of the latex and preparation of the product for the market: —

Government House, Entebbe, Uganda,
January 3, 1907.
